THEORETICAL INVESTIGATION AT SUBSONIC SPEEDS OF THE FLOW AHEAD OF A SLENDER INCLINED PARABOLIC-ARC BODY OF REVOLUTION AND CORRELATION WITH EXPERIMENTAL DATA OBTAINED AT LOW SPEEDS. William Letko and Edward C. B. Danforth, III. July 1954. 56p. diagrs. (NACA TN 3205)

Approximate formulas, based on subsonic linearized theory, are derived for the static-pressure increment and flow inclination ahead of slender inclined parabolic-arc bodies of revolution at subsonic speeds. Charts are presented from which these quantities can be estimated. Some comparisons with experimental data obtained for a Mach number of 0.21 are also presented. Consideration is given to the induced effects of the wing and mounting boom on flow-inclination measurements.

NACA TN 3208

HEAT, MASS, AND MOMENTUM TRANSFER FOR FLOW OVER A FLAT PLATE WITH BLOWING OR SUCTION. H. S. Mickley, R. C. Ross, A. L. Squyers and W. E. Stewart, Massachusetts Institute of Technology. July 1954. ii, 149p. diagrs., photos., 9 tabs. (NACA TN 3208)

The effect on the boundary layer of sucking or blowing air through a porous flat plate into or out of a main air stream flowing parallel to the plate was studied theoretically and experimentally. Laminar-boundary-layer theory was used to calculate transfer coefficients and velocity, temperature, and concentration profiles in laminar, zero Euler number flow under certain restricted mass transfer conditions and for a range of Prandtl or Schmidt numbers. For turbulent flow film theory was used to predice the effect of mass transfer on friction, heat, and mass transfer coefficients. Experimental measurements of velocity and temperature profiles and of friction and heat transfer coefficients were carried out over a range of flow conditions.

NACA TN 3225

AN EXPERIMENTAL STUDY OF THE LIFT AND PRESSURE DISTRIBUTION ON A DOUBLE-WEDGE PROFILE AT MACH NUMBERS NEAR SHOCK ATTACHMENT. Walter G. Vincenti, Duane W. Dugan and E. Ray Phelps. July 1954. 43p. diagrs. (NACA TN 3225)

An account is given of measurements at low supersonic speeds of the pressure distribution on a double-wedge profile. The results cover the Mach number range from 1.166 to 1.377, which brackets the value (1.221) for bow-wave attachment at zero angle of attack. The results are discussed and compared with the findings of the transonic small-disturbance theory.

NACA TN 3255

SHOCK-TURBULENCE INTERACTION AND THE GENERATION OF NOISE. H. S. Ribner. July 1954. 60p. diagrs., tab. (NACA TN 3255)

Interaction of convected field of turbulence with shock wave is analyzed to yield modified turbulence, entropy spottiness, and noise generated downstream of the shock. Analysis is generalization of single-spectrum-wave treatment of TN 2864. Formulas for spectra and correlations are obtained. Numerical calculations yield curves of rms velocity components, temperature, pressure, and noise in db against Mach number for $M = 1$ to ∞; both isotropic and strongly axisymmetric (lateral/longitudinal = 36/1) initial turbulence are treated. In either case, turbulence of 0.1 percent longitudinal component generates about 120 dbs of noise.

NACA TN 3256

EXPERIMENTAL INVESTIGATION OF TEMPERATURE RECOVERY FACTORS ON A 10° CONE AT ANGLE OF ATTACK AT A MACH NUMBER OF 3.12. John R. Jack and Barry Moskowitz. July 1954. 15p. diagrs. (NACA TN 3256)

At angles of attack from 0° to 10° over the Reynolds number range (1.5 to 8×10^6), an increase in angle of attack increased the equilibrium surface temperatures in the laminar and turbulent flow regions. The equilibrium surface temperatures in regions of probable cross-flow separation were in the same range as those obtained for fully turbulent flow. For the windward surface, local recovery factors in the fully laminar and turbulent regions were not significantly affected by changes in angle of attack.

A METHOD FOR CALIBRATING A WIND TUNNEL REAR STING BALANCE. J. R. Anderson. March 1954. 14p. diagrs., tab. (RAE Tech. Note Aero 2299)

A method is described for calibrating a wind-tunnel balance consisting of a sting support bearing strain gages. The form of calibration obtained is essentially suitable for the automatic computing of wind-tunnel results. The technique of static loading of the balance is discussed, and an appendix contains practical notes on matrix inversion.

AN APPLICATION OF THE CAPACITY PROBE METHOD TO THE MEASUREMENT OF ROTOR BLADE TIP DEFLECTIONS IN AN AXIAL COMPRESSOR. R. Chaplin. December 1953. 35p. diagrs., photos. (NGTE Memo. M. 199)

An application to the first rotor stage of an axial compressor, or the capacity probe method of measuring blade tip deflections is described. Results obtained from strain gages on the same stage are included. Results from the capacity probe method were not satisfactory and it is suggested that the standards of stability required by this method were not practicable in this instance.

INVESTIGATIONS INTO GLUES AND GLUING. PROGRESS REPORT SEVENTY-SIX - MARCH 1954. DURABILITY TESTS ON PLYWOOD ADHESIVES - SERIES II. ANALYSIS AFTER SEVEN AND A HALF YEARS. R. A. G. Knight, R. J. Newall and J. E. Grosert. 9p. 4 tabs. (Forest Products Research Lab. Supersedes Progress reports 44, 46, 46 (add.) and 60)

This report analyzes the behavior of a range of adhesives used in beech plywood exposed to four natural conditions: storage in a normally heated workshop; exposure to the weather on racks facing south in an open field; storage in an open-sided shed and momentarily dipped in water once a month; and submersion in fresh water tanks standing in the open. The adhesives include a number of phenolic and resorcinol resins, one experimental melamine, fortified and normal ureas, casein and animal glues and sodium silicate.

ON THE MAGNUS EFFECT ACCORDING TO THE ASYMPTOTIC HYDRODYNAMIC THEORY. (Über den Magnuseffekt nach der Asymptotischen Hydrodynamischen Theorie). Torsten Gustafson. June 1954. ii, 93p. diagrs., photos. (Trans. from Hakan Ohlssons Buchdruckerei, Lund, 1933)

A comparison of the theoretically and experimentally determined values of pressure, drag, and lift on a rotating cylinder in fluid flow gives information on how far the asymptotic flow theory is capable of reproducing the characteristic properties of the actual flow in the case of small friction. The pressure values as well as the lift coefficients agree with experiments. For a prescribed flow in the case of small friction the flow process can be represented by determination of the wake form and formation of the corresponding potential expressions.

DIRECT MEASUREMENTS OF SKIN FRICTION. Satish Dhawan, California Institute of Technology. 1953. ii, 20p. diagrs., photos. (NACA Rept. 1121. Formerly TN 2567)

A device was developed to measure local skin friction on a flat plate by measuring the force exerted on a very small movable part of the flat plate. The apparatus was applied to measurements in the low-speed range, for both laminar and turbulent boundary layers, and the measured skin-friction coefficients show excellent agreement with Blasius' and Von Kármán's results. Measurements were made in high-speed subsonic flow and turbulent-skin-friction coefficients were determined up to a Mach number of about 0.8. A few measurements were also made in supersonic flow.

NACA Rept. 1122

SURVEY OF PORTIONS OF THE CHROMIUM-COBALT-NICKEL-MOLYBDENUM QUATERNARY SYSTEM AT 1200° C. Sheldon Paul Rideout and Paul A. Beck, University of Notre Dame. 1953. ii, 38p. diagrs., photos., 20 tabs. (NACA Rept. 1122. Formerly TN 2683)

A survey was made of portions of the chromium-cobalt-nickel-molybdenum quaternary system at 1200° C by means of microscopic and X-ray diffraction studies. Since the face-centered cubic (alpha) solid solutions form the matrix of almost all practically useful high-temperature alloys, the solid solubility limits of the quaternary alpha phase were determined up to 20 percent molybdenum. The component cobalt-nickel-molybdenum, chromium-cobalt-molybdenum, and chromium-nickel-molybdenum ternary systems were also studied. The survey of these systems was confined to the determination of the boundaries of the face-centered cubic (alpha) solid solutions and of the phases coexisting with alpha at 1200° C.

NACA RM E54E19

EFFECTS OF ADDITIVES ON CORROSION AND MASS TRANSFER IN SODIUM HYDROXIDE - NICKEL SYSTEMS UNDER FREE-CONVECTION CONDITIONS. Americo F. Forestieri. August 1954. 13p. diagrs., photos., 6 tabs. (NACA RM E54E19)

Experiments were carried out under free-convection conditions in sodium hydroxide - "L" nickel systems. Nickel crucibles half full of sodium hydroxide were heated for 24 hours at 1500° F with a temperature difference of 45° F. The effect of additives such as metals, salts, oxides, and nitrides on the extent of corrosion and mass transfer was determined by measurement of the weight change of a specimen in the hot zone, and by metallographic examination of the specimen cross section. Reduction in mass transfer occurred with additives of powdered chromium and aluminum.

NACA RM E54F10

PRELIMINARY INVESTIGATION OF STRESS-RUPTURE AND TENSILE STRENGTH OF THERMENOL, AN IRON-ALUMINUM ALLOY. Charles A. Gyorgak. August 1954. 11p. diagrs., 3 tabs. (NACA RM E54F10)

An investigation determined the stress-rupture life at 1100° and 1200° F, the room-temperature tensile strength, and the bend ductility of the oxidation-resistant iron-aluminum alloy Thermenol. Stress-rupture strengths for 100-hour life were 19,300 psi at 1200° F and 35,500 psi at 1100° F. The room-temperature tensile strength was 62,050 psi with 3-percent elongation in a 3/4-inch-gage length. Angles of bend to cause failure in the longitudinal and transverse directions ranged from 34° to 56° and were approximately equal.

NACA TN 3155

IMPINGEMENT OF WATER DROPLETS ON NACA 65A004 AIRFOIL AT 8° ANGLE OF ATTACK. Rinaldo J. Brun, Helen M. Gallagher and Dorothea E. Vogt. July 1954. 27p. diagrs. (NACA TN 3155)

The trajectories of droplets in the air flowing past an NACA 65A004 airfoil at an angle of attack of 8° were determined. The amount of water in droplet form impinging on the airfoil, the area of droplet impingement, and the rate of droplet impingement per unit area on the airfoil surface were calculated from the trajectories and presented to cover a large range of flight and atmospheric conditions. These impingement characteristics are compared briefly with those previously reported for the same airfoil at an angle of attack of 4°.

NACA TN 3178

CHARACTERISTICS OF TURBULENCE IN A BOUNDARY LAYER WITH ZERO PRESSURE GRADIENT. P. S. Klebanoff, National Bureau of Standards. July 1954. 56p. diagrs. (NACA TN 3178)

The results of an experimental investigation of a turbulent boundary layer with zero pressure gradient are presented. Measurements with the hot-wire anemometer were made of turbulent energy and turbulent shear stress, probability density and flattening factor of u-fluctuation, spectra of turbulent energy and shear stress, and turbulent dissipation. The importance of the region near the wall and the inadequacy of the concept of local isotropy are demonstrated. Attention is given to the energy balance and the intermittent character of the outer region of the boundary layer. Also several interesting features of the spectral distribution of the turbulent motions are discussed.

NACA TN 3209

HIGH-RESOLUTION AUTORADIOGRAPHY. George C. Towe, Henry J. Gomberg and J. W. Freeman, University of Michigan. July 1954. ii, 138p. diagrs., photos., 9 tabs. (NACA TN 3209)

This investigation was made to adapt wet-process autoradiography to metallurgical samples to obtain high resolution of segregated radioactive elements in microstructures. Results are confined to development of the technique, which was perfected to a resolution of less than 10 microns. The radioactive samples included carbon-14 carburized iron and steel, nickel-63 electroplated samples, a powder product containing nickel-63, and tungsten-185 in N-155 alloy.

NACA TN 3269

ADDITIONAL STATIC AND FATIGUE TESTS OF HIGH-STRENGTH ALUMINUM-ALLOY BOLTED JOINTS. E. C. Hartmann, Marshall Holt and I. D. Eaton, Aluminum Company of America. July 1954. 42p. diagrs., photos., 7 tabs. (NACA TN 3269)

Additional static and fatigue tests were made on a few types of joints in 75S-T6, 24S-T4, and 14S-T6 high-strength aluminum-alloy extruded bar in order to supplement the data in NACA Technical Note 2276. Comparisons are made with the results of these earlier tests.

Royal Aircraft Establishment (Gt. Brit.) MECHANICAL PROPERTIES OF SOME D. T. D. COMMERCIAL ALUMINIUM ALLOY SHEET MATERIALS. D. C. Hayward. March 1954. 26p. diagrs., 5 tabs. (RAE Tech. Note Met. 195)

Compressive and tensile tests on aluminum alloy sheet D. T. D. 603, 646, 546, 610, and 687 were made longitudinally and transversely to the rolling direction. Tables of proof-strength values and the tangent-moduli graphs derived are given. Artificial aging was found for small plastic deformation, to raise the stress level of the compressive tangent-moduli curves more than the tensile tangent-moduli curves. The effect of sheet thickness on strength values, investigated for D. T. D. 546 only, showed progressive increase of tensile proof-stress with increase in thickness but under compression, strength varied irregularly with sheet thickness.

DECLASSIFIED NACA REPORTS

THE FOLLOWING REPORT HAS BEEN DECLASSIFIED FROM CONFIDENTIAL, 7/29/54.

RM L52C21

NACA RM A9E05

THE AERODYNAMIC CHARACTERISTICS THROUGHOUT THE SUBSONIC SPEED RANGE OF A THIN, SHARP-EDGED HORIZONTAL TAIL OF ASPECT RATIO 4 EQUIPPED WITH A CONSTANT-CHORD ELEVATOR. Angelo Bandettini and Verlin D. Reed. June 30, 1949. 50p. diagrs., photo. (NACA RM A9E05) (Declassified from Confidential, 7/29/54)

The report presents results of tests at Mach numbers from 0.20 to 0.94 of a thin horizontal tail without sweep having an aspect ratio of 4 and taper ratio of 0.5 and equipped with a constant-chord elevator. The tail profile was a sharp-edged, faired double wedge having a thickness-chord ratio of 0.042. The investigation was made at a constant Reynolds number of 2,000,000. The effect of compressibility on the effectiveness of the elevator in producing lift at small angles of attack and elevator deflections was small at Mach numbers less than 0.60; there was a gradual increase in effectiveness between 0.60 and 0.90 Mach numbers and a slight decrease between Mach numbers of 0.90 and 0.94.

NACA RM A9K18

THE EFFECT OF ASPECT RATIO ON THE SUBSONIC AERODYNAMIC CHARACTERISTICS OF WINGS WITH NACA 65_1-210 SECTIONS. Warren H. Nelson and Albert L. Erickson. February 3, 1950. 31p. diagrs., photos., tab. (NACA RM A9K18) (Declassified from Confidential, 7/29/54)

The lift, drag, and pitching-moment characteristics of four model wings of aspect ratios 1, 2, 4, and 6 are presented. The wings all had NACA 65_1-210 sections, taper ratios of 0.4, and 3° dihedral. The 25-percent-chord lines had no sweep. Data were obtained for a Mach number range of 0.4 to 0.9, and an angle-of-attack range of -4° to 20°. The transition location and its effect on drag are studied.

NACA RM A53I01

APPLICATIONS OF AUXILIARY AIR INJECTORS TO SUPERSONIC WIND TUNNELS. Joseph M. Spiegel, Robert U. Hofstetter and Donald M. Kuehn. November 1953. 53p. diagrs., photos. (NACA RM A53I01) (Declassified from Confidential, 7/29/54)

The use of an air injector as an auxiliary device for reducing starting and running compression ratios of wind tunnels is discussed. A one-dimensional analysis and experimental data are presented to demonstrate the advantages of the device. A design procedure is included for application of the method to existing or proposed wind tunnels.

NACA RM A53L18

EXPERIMENTAL DETERMINATION OF BOUNDARY-LAYER TRANSITION ON A BODY OF REVOLUTION AT M = 3.5. James R. Jedlicka, Max E. Wilkins and Alvin Seiff. March 1954. 56p. diagrs., photos. (NACA RM A53L18) (Declassified from Confidential, 7/29/54)

Boundary-layer-transition tests were made in free flight through still air on a small-scale fin-stabilized body of revolution of fineness ratio 30 at a Mach number of 3.5 and length Reynolds numbers of 12 and 24 million. Three types of surfaces were tested and the transition Reynolds number was found to depend critically on the surface smoothness. Angle of attack was found to influence transition strongly. This effect was correlated in terms of pressure rise along streamlines and led to a prediction of the effect of varying the body shape on sheltered-side transition. In general, the transition points were time dependent, fluctuating in one case over a range of Reynolds numbers from 4 to 20 million. Steady laminar flow was observed to a length Reynolds number of 11 million. Transition due to roughness and adverse pressure gradient occurred even though the tests were within the region of theoretical infinite laminar stability to small disturbances.

NACA RM E50F22

FABRICATION AND PROPERTIES OF HOT-PRESSED MOLYBDENUM DISILICIDE. Roger A. Long. August 24, 1950. 34p. diagrs., photos., tab. (NACA RM E50F22) (Declassified from Confidential, 7/29/54)

Hot-pressed molybdenum disilicide bodies produced by industrial methods and sources were evaluated. The outstanding characteristics reported are an elevated-temperature (2400° F) short-time tensile strength of 41,070 pounds per square inch and a 100-hour rupture stress at 1800° F in excess of 30,000 pounds per square inch, as indicated in a preliminary evaluation. The material evaluated was extremely resistant to air corrosion up to 2850° F and generally brittle at temperatures below 2200° F.

NACA RM E51D27

INSTRUMENTATION FOR RECORDING TRANSIENT PERFORMANCE OF GAS-TURBINE ENGINES AND CONTROL SYSTEMS. Gene J. Delio and Glennon V. Schwent. June 27, 1951. 27p. diagrs., photos. (NACA RM E51D27) (Declassified from Confidential, 7/29/54)

Design features are presented for the instrumentation used in a study of the transient performance of gas-turbine engines and control systems. The dynamic characteristics of the instrumentation are discussed and examples are given of typical data on the acceleration of a controlled and an uncontrolled engine.

NACA RM E51K26

PRESSURE DISTRIBUTION AND AERODYNAMIC COEFFICIENTS ASSOCIATED WITH HEAT ADDITION TO SUPERSONIC AIR STREAM ADJACENT TO TWO-DIMENSIONAL SUPERSONIC WING. I. Irving Pinkel, John S. Serafini and John L. Gregg. February 1952. 33p. diagrs., tab. (NACA RM E51K26) (Declassified from Confidential, 7/29/54)

The modifications in the pressure distributions and the aerodynamic coefficients associated with additions of heat to the two-dimensional supersonic inviscid flow field adjacent to the lower surface of a 5-percent-thickness symmetrical circular-arc wing are presented in this report. The pressure distributions are obtained by the use of a graphical method which gives the two-dimensional supersonic inviscid flow field obtained with moderate heat addition. The variation is given of the lift-drag ratio and of the aerodynamic coefficients of lift, drag, and moment with free stream Mach number, angle of attack, and parameters defining extent and amount of heat addition. The six graphical solutions used in this study included Mach numbers of 3.0 and 5.0 and angles of attack of 0° and 2°.

NACA RM E52A17

PRELIMINARY INVESTIGATION OF THE HEAT-SHOCK RESISTANT PROPERTIES OF MOLYBDENUM DISILICIDE BLADES UNDER CENTRIFUGAL LOAD. Roger A. Long and John C. Freche. May 1952. 15p. diagrs., photos., tab. (NACA RM E52A17) (Declassified from Confidential, 7/29/54)

An investigation to determine the heat-shock resistant properties of two molybdenum disilicide turbine blades under centrifugal loads imposed by turbine rotation is presented. Molybdenum disilicide turbine blades fabricated by hot-pressing techniques withstood heat-shock conditions under blade centrifugal stresses up to 5350 pounds per square inch. Additional development is required before the heat-shock resistant properties of molybdenum disilicide are satisfactory for turbine-blade application.

NACA RM E52B06

SOME FACTORS AFFECTING FABRICATION AND HIGH-TEMPERATURE STRENGTH OF MOLYBDENUM DISILICIDE. W. A. Maxwell. April 1952. 25p. diagrs., photos., 3 tabs. (NACA RM E52B06) (Declassified from Confidential, 7/29/54)

It has been demonstrated that the short-time high-temperature strength of sintered molybdenum disilicide can be greatly improved by carbon addition. Improved long-time deformation properties and decreased high-temperature plasticity accompany the carbon additions. These changes are attributed to partial deoxidation by the carbon. Large-grain, hot-pressed molybdenum disilicide having a low oxygen content was found to have superior long-time properties. Hardness and other properties were found to be variable over a wide range.

NACA RM E52D09

SOME STRESS-RUPTURE AND CREEP PROPERTIES OF MOLYBDENUM DISILICIDE IN THE RANGE 1600° TO 2000° F. W. A. Maxwell. June 1952. 19p. diagrs., photos., 2 tabs. (NACA RM E52D09) (Declassified from Confidential, 7/29/54)

An investigation of the stress-rupture and creep properties of hot-pressed molybdenum disilicide has produced the following results: 1. The long-time strength of molybdenum disilicide at high temperatures is superior to that of the high-temperature alloys and titanium carbide ceramals. 2. The use of molybdenum disilicide above 1800° F may be limited by the creep rate rather than by the stress-rupture life. 3. A comparatively convenient and satisfactory method for creep and stress-rupture testing to 2000° F has been developed.

NACA RM L9B24a

AN EXPERIMENTAL INVESTIGATION OF A GYRO-ACTUATED ROLL CONTROL SYSTEM INSTALLED IN A SUBSONIC TEST VEHICLE. Jerome M. Teitelbaum and Ernest C. Seaberg. April 20, 1949. 26p. diagrs., photos., tab. (NACA RM L9B24a) (Declassified from Confidential, 7/29/54)

Contains the results of wind-tunnel and flight tests of a gyro-actuated, roll control system installed in a sweptback four-wing subsonic test vehicle. This control system links the control surface directly to the displacement gyroscope and employs a torque motor to limit gyroscope precession. The linking of the control surfaces in this manner results in an autopilot system which gives a no-lag control response to a model displacement without resorting to velocity or acceleration-sensitive devices.

NACA RM L9F15a

LABORATORY INVESTIGATION OF AN AUTOPILOT UTILIZING A MECHANICAL LINKAGE WITH A DEAD SPOT TO OBTAIN AN EFFECTIVE RATE SIGNAL. Ernest C. Seaberg. August 17, 1949. 29p. diagrs., photos., tab. (NACA RM L9F15a) (Declassified from Confidential, 7/29/54)

The results of a laboratory investigation of a frontlash autopilot are presented in this analysis. The operation of this autopilot is based on the nonlinear principle of utilizing a dead spot in the servomotor feedback linkage to the gyroscope base reference as a means of obtaining a leading control signal. The investigation consists of oscillating-table tests in order to determine the effect of frontlash on the amplitude and phase responses of the system. Roll-simulator tests were also conducted in order to confirm the possibility of stabilization of pilotless aircraft with this type of automatic pilot, and an attempt to bracket the usable range of this autopilot was made by plotting the degree of stability as a function of the aerodynamic roll parameters.

NACA RM L50B13

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF A 45° SWEPTBACK HORIZONTAL TAIL WITH PLAIN AND HORN-BALANCED CONTROL SURFACES. Harold S. Johnson and Robert F. Thompson. March 31, 1950. 44p. diagrs., photo., tab. (NACA RM L50B13) (Declassified from Confidential, 7/29/54)

A wind-tunnel investigation of a horizontal tail surface having 45° of sweepback was made through a speed range to a Mach number of 0.89. The 0.25-chord plain flap was tested with and without a horn balance. A comparison is made with the results of a previous investigation of the same model equipped with a larger horn balance. Presented are lift, drag, pitching-moment, and hinge-moment data and lift and hinge-moment parameters.

NACA RM L50F29

STATIC DIRECTIONAL STABILITY OF A TANDEM-HELICOPTER FUSELAGE. Charles C. Smith, Jr. August 9, 1950. 23p. diagrs., photo. (NACA RM L50F29) (Declassified from Confidential, 7/29/54)

An investigation has been made to determine the static directional stability of a fuselage typical of tandem helicopters. The model consisted mainly of an elliptical-cross-section body and a rear rotor pylon faired to form a large vertical tail with a very thick airfoil section. The investigation included a study of the effect of various modifications to the vertical tail surface on the directional stability of the model.

NACA RM L50I19

THEORETICAL INVESTIGATION OF A PROPORTIONAL-PLUS-FLICKER AUTOMATIC PILOT. Ernest C. Seaberg. October 19, 1950. 54p. diagrs., photo., tab. (NACA RM L50I19) (Declassified from Confidential, 7/29/54)

An analysis has been made of the stability of a supersonic canard airframe and a proportional-plus-flicker autopilot. Essentially, this autopilot maintains a zero reference about which the output is proportional to the input and a flicker response overrides this proportional response at a fixed angle of gimbal displacement on either side of the zero gyroscope reference. The analysis consists of an investigation of the calculated transient responses based on the variation of the autopilot and aerodynamic parameters. The calculations are based on the assumption that the proportional part of the system either contains a zero-phase-lag proportional autopilot or is the actual autopilot frequency response approximated by mathematical transfer function.

NACA RM L50I21

DESCRIPTION AND INVESTIGATION OF A DYNAMIC MODEL OF THE XH-17 TWO-BLADE JET-DRIVEN HELICOPTER. George W. Brooks and Maurice A. Sylvester. March 14, 1951. 49p. diagrs., photos., 6 tabs. (NACA RM L50I21) (Declassified from Confidential, 7/29/54)

A description of the NACA 1/10-scale dynamic model of the XH-17 two-blade jet-powered helicopter is presented and the investigation of the model flutter and ground-vibrations characteristics reported. At design values, rotor-blade flutter of the classical bending-torsion type was observed at speeds corresponding to full-scale tip speeds near the over-speed limit of 800 feet per second. The flutter speed could be raised by increasing the torsional frequencies of the blades and changing the blade chordwise mass distribution. The type of flutter mode depended on whether the model was externally excited. No unstable ground vibrations could be excited on the model.

NACA RM L51F06

EXPLORATORY INVESTIGATION AT HIGH AND LOW SUBSONIC MACH NUMBERS OF TWO EXPERIMENTAL 6-PERCENT-THICK AIRFOIL SECTIONS DESIGNED TO HAVE HIGH MAXIMUM LIFT COEFFICIENTS. Laurence K. Loftin, Jr. and Albert E. von Doenhoff. December 1951. 48p. diagrs., photo., 2 tabs. (NACA RM L51F06) (Declassified from Confidential, 7/29/54)

The development of a method for deriving thin airfoil sections to have high values of the low-speed maximum lift coefficient is described and the results of an experimental investigation at high and low subsonic Mach numbers of two new symmetrical airfoils of 6-percent thickness are presented. Maximum lift coefficients of about 1.3 were obtained for the two airfoils at low speeds.

CURRENT NACA REPORTS

NACA Rept. 1141

METHOD AND GRAPHS FOR THE EVALUATION OF AIR-INDUCTION SYSTEMS. George B. Brajnikoff. 1953. ii, 22p. diagrs., tab. (NACA Rept. 1141. Formerly TN 2697)

Graphs that allow rapid evaluation of air-induction systems from considerations of their aerodynamic parameters in combination with power-plant characteristics are presented for the supersonic Mach numbers up to 3.0. Restrictions imposed by the engine characteristics on the use of a fixed-size air inlet are discussed and illustrated by means of sample solutions. The relation between the engine characteristics, flight conditions, inlet characteristics, and inlet area for optimum performance is given.

NACA Rept. 1142

DIFFUSION OF HEAT FROM A LINE SOURCE IN ISOTROPIC TURBULENCE. Mahinder S. Uberoi and Stanley Corrsin, Johns Hopkins University. 1953, ii, 29p. diagrs., photos., tab. (NACA Rept. 1142. Formerly TN 2710)

An experimental and analytical study has been made of some features of the turbulent heat diffusion behind a line heated wire stretched perpendicular to a flowing isotropic turbulence. The mean temperature distributions have been measured with systematic variations in wind speed, size of turbulence producing grid, and downstream location of heat source. The nature of the temperature fluctuation field has been studied. A comparison of Lagrangian and Eulerian analyses for diffusion in a nondecaying turbulence yields an expression for turbulent-heat-transfer coefficient in terms of turbulence velocity and a Lagrangian "scale." A convenient form has been deduced for the criterion of interchangeability of instantaneous space and time derivatives in a flowing turbulence.

NACA TM 1365

PAPERS ON SHIMMY AND ROLLING BEHAVIOR OF LANDING GEARS PRESENTED AT STUTTGART CONFERENCE OCT. 16 AND 17, 1941. (Bericht über die Sitzung Flattern und Rollverhalten von Fahrwerken am 16./17. Oktober 1941 in Stuttgart). August 1954. ii, 233p. diagrs., photos., 2 tabs. (NACA TM 1365. Trans. from Lilienthal-Gesellschaft für Luftfahrtforschung, Berlin, Bericht 140)

This report is a compilation of 16 papers dealing with landing gear behavior and tire characteristics which were presented at a conference in Stuttgart in 1941. Four of these papers deal with the rolling stability or veering-off tendency of nose and tail wheel tricycle landing gears. Four others deal with theoretical and experimental studies of the characteristics of pneumatic tires including the side elasticity, the cornering characteristics, and the force distribution between tire and runway. The remaining eight papers deal with theoretical and experimental studies of wheel shimmy.

NACA RM 54G26

EFFECTS OF RESIN COATING METHODS AND OTHER VARIABLES ON PHYSICAL PROPERTIES OF GLASS-FABRIC REINFORCED POLYESTERS. B. M. Axilrod, J. E. Wier and J. Mandel, National Bureau of Standards. August 1954. 22p., 6 tabs. (NACA RM 54G26)

Effects of resin coating methods on properties of glass-fabric laminates with three finishes and two polyester resins were investigated. Coating methods were roller, use of dilute resin solution, resin immersion, use of monomeric styrene, and vacuum impregnation. A normal high-temperature rapid cure and a moderate-temperature slow cure were used. Laminate preparation followed a statistical design to minimize uncontrollable variables. Tests included flexural strength both dry and after water immersion, specific gravity, resin content, and voids content.

NACA RM E54F11

EXPERIMENTAL HEAT-TRANSFER AND FRICTION COEFFICIENTS FOR AIR FLOWING THROUGH STACKS OF PARALLEL FLAT PLATES. Eldon W. Sams and Walter F. Weiland, Jr. August 1954. 33p. diagrs., photo., tab. (NACA RM E54F11)

Forced-convection heat-transfer and pressure-drop data were obtained for stacks of parallel flat plates of short length-to-effective-diameter ratio. Two such stacks were alined and misalined in the direction of air flow with gap spacings between stacks of 1/32, 1/8, and 1/4 inch. Data were obtained with heat addition to the downstream stack only over a range of Reynolds number from 15,000 to 80,000 and average surface temperatures of about 680° R. The average and local heat-transfer coefficients were only slightly higher than predicted values from established round tube data. The friction data for both stacks are compared.

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

NACA RM E54F29

A STUDY OF THE RADIATION FROM LAMINAR AND TURBULENT OPEN PROPANE-AIR FLAMES AS A FUNCTION OF FLAME AREA, EQUIVALENCE RATIO, AND FUEL FLOW RATE. Thomas P. Clark and David A. Bittker. August 1954. 33p. diagrs., photos., 2 tabs. (NACA RM E54F29)

For laminar flames of given equivalence ratio, radiation intensity changes linearly with fuel flow rate and photographically measured surface area. Intensity per unit area depends only on equivalence ratio. Turbulent flame radiation intensity is also proportional to fuel flow rate. Laminar and turbulent flames at identical conditions of flow, equivalence ratio, and burner diameter have about the same radiation intensities. Furthermore, the spectral intensity distributions appear to be the same for both types of flame, suggesting that the kinetics may also be the same. These results are compatible with the "extended surface" concept of turbulent flame structure, but do not rule out other theories.

NACA RM E54F29a

SPARK IGNITION OF FLOWING GASES. IV - THEORY OF IGNITION IN NONTURBULENT AND TURBULENT FLOW USING LONG-DURATION DISCHARGES. Clyde C. Swett, Jr. August 1954. 29p. diagrs., 2 tabs. (NACA RM E54F29a)

A theory of spark ignition is presented that is based on the concept that only a portion of the discharge length, a line source of ignition, is important in the ignition process. Theoretical and experimental comparisons of the energy in this heated zone reveal a relation among the variables of total spark-discharge energy, gas density and velocity, electrode spacing, spark duration, intensity of turbulence, and fuel constants. The limited data available substantiate this relation.

NACA RM L54G02

RAPID ESTIMATION OF BENDING FREQUENCIES OF ROTATING BEAMS. Robert T. Yntema. August 1954. 18p. diagrs., tab. (NACA RM L54G02)

A procedure is presented in the form of charts which permits the rapid estimation of the natural bending frequencies of helicopter rotor blades both rotating and nonrotating. Since the approach is based on the Southwell equation, an evaluation of the method with regard to such things as higher modes, blade offset, and variable mass and stiffness distribution is also given. The evaluation shows that when nonrotating beam bending modes are used, the Southwell equation yields reasonably accurate bending frequencies for rotating helicopter blades. Example comparisons of frequencies estimated using the charts with values given by the manufacturer for several actual blades show that the simplified procedure yields good practical results.

NACA TN 3197

MECHANICAL PROPERTIES AT ROOM TEMPERATURE OF FOUR CERMETS OF TITANIUM CARBIDE WITH NICKEL BINDER. Aldie E. Johnson, Jr. August 1954. 22p. diagrs., photos., tabs. (NACA TN 3197)

Room-temperature stress-strain curves are presented for compression, tension, and shear loadings on four compositions of titanium carbide with nickel binder. Values of ultimate strength, modulus of elasticity, modulus of rigidity, Poisson's ratio in the elastic region, density, and hardness for the four materials are tabulated.

NACA TN 3206

TORSIONAL VIBRATIONS OF HOLLOW THIN-WALLED CYLINDRICAL BEAMS. Edwin T. Kruszewski and Eldon E. Kordes. August 1954. 33p. diagrs., tab. (NACA TN 3206)

Theoretical analyses of the torsional vibrations of hollow thin-walled cylinders are presented. Solutions for beams of arbitrary doubly symmetrical cross section with uniform wall thickness are given for cantilever and free-free beam vibrations. Numerical results are shown for cylinders of rectangular cross section and the influence of bending stresses due to torsion and longitudinal inertia is discussed. The solutions for beams of rectangular cross section are used to investigate the accuracy of a solution based on an analysis of a four-flange box beam.

NACA TN 3212

A NONLINEAR THEORY OF BENDING AND BUCKLING OF THIN ELASTIC SHALLOW SPHERICAL SHELLS. A. Kaplan and Y. C. Fung, California Institute of Technology. August 1954. 58p. diagrs., photo., 5 tabs. (NACA TN 3212)

The problem of the finite displacement and buckling of a shallow spherical dome is investigated both theoretically and experimentally. Experimental results seem to indicate that the classical criterion of buckling is applicable to very shallow spherical domes for which the theoretical calculation was made. A transition to energy criterion for higher domes is also indicated.

NACA TN 3223

AN ANALYSIS OF SHOCK-WAVE CANCELLATION AND REFLECTION FOR POROUS WALLS WHICH OBEY AN EXPONENTIAL MASS-FLOW PRESSURE-DIFFERENCE RELATION. Joseph M. Spiegel and Phillips J. Tunnell. August 1954. 23p. diagrs. (NACA TN 3223)

Conditions are derived for cancellation and reflection of two-dimensional shock waves from porous walls with wall suction. An exponential relation between mass flow and pressure differential across the walls is assumed. Applications to three-dimensional shock waves are discussed.

NACA TN 3224

THEORETICAL INVESTIGATION OF THE EFFECTS UPON LIFT OF A GAP BETWEEN WING AND BODY OF A SLENDER WING-BODY COMBINATION. Duane W. Dugan and Katsumi Hikido. August 1954. 41p. diagrs. (NACA TN 3224)

Slender-body theory is applied to determine the effects upon lift of a gap between wing and body of a slender wing-body combination. Two cases are considered, one in which the wing and body are both inclined at the same angle with respect to the free stream, the other in which the body remains at zero angle of attack and the wing is deflected with respect to the body.

NACA TN 3226

SOME POSSIBILITIES OF USING GAS MIXTURES OTHER THAN AIR IN AERODYNAMIC RESEARCH. Dean R. Chapman. August 1954. 48p. diagrs., 4 tabs. (NACA TN 3226)

A study is made of possible uses in compressible-flow research of various gas mixtures having the same specific-heat ratio as air. Such mixtures require low wind-tunnel power and have other possible applications in compressor research and firing-range research. Certain gas mixtures can be concocted which behave at wind-tunnel temperatures dynamically similar to air at flight temperatures.

NACA TN 3229

THE SMALL-DISTURBANCE METHOD FOR FLOW OF A COMPRESSIBLE FLUID WITH VELOCITY POTENTIAL AND STREAM FUNCTION AS INDEPENDENT VARIABLES. Carl Kaplan. August 1954. 18p. (NACA TN 3229)

The equations of two-dimensional compressible flow are treated according to the Prandtl-Busemann small-disturbance method. In contrast to the usual procedure, the independent variables are the compressible velocity potential and stream function and the dependent variables are the rectangular Cartesian coordinates in the plane of flow. The six first-order differential equations corresponding to the first three iteration steps are put into complex-vector form. The particular integrals of the resulting set of three equations are then directly obtained. As an example, the general results of the analysis are applied to the case of subsonic compressible flow past a sinusoidal wall of small amplitude.

NACA TN 3232

AN ANALYSIS OF THE STABILITY AND ULTIMATE BENDING STRENGTH OF MULTIWEB BEAMS WITH FORMED-CHANNEL WEBS. Joseph W. Semonian and Roger A. Anderson. August 1954. 28p. diagrs., photos. (NACA TN 3232)

Design curves and procedures are presented for calculating the stresses at which wrinkling instability and failure occur in multiweb beams with formed-channel webs. The theory is compared with test data for multiweb beams in bending and a criterion is given for predicting whether a given beam will be susceptible to a wrinkling instability or will buckle in a local mode. The specification for riveting the web attachment flanges to the cover skins of the beams is shown to be an important factor in determining the ultimate strength of this type of construction.

NACA TN 3233

A REVIEW OF PLANING THEORY AND EXPERIMENT WITH A THEORETICAL STUDY OF PURE-PLANING LIFT OF RECTANGULAR FLAT PLATES. Charles L. Shuford, Jr. August 1954. 34p. diagrs. (NACA TN 3233)

A summary is given of the background and present status of the pure-planing flat-plate lift theories. The fundamental assumptions and applicability to actual calculation of the planing lift force are reviewed. A proposed theory based on the consideration of linear lifting-line theory less the suction component of lift plus crossflow effects is presented. A comparison of this theory with existing planing formulas and experimental data is made. The agreement between the results calculated by the proposed theory and the experimental data is satisfactory for engineering calculations of pure-planing rectangular-flat-plate lift and center of pressure.

NACA TN 3234

REDUCTION OF HELICOPTER PARASITE DRAG. Robert D. Harrington. August 1954. 8p. diagrs. (NACA TN 3234)

A reduction in helicopter parasite drag is possible but not profitable except in those cases where high speed and long range are primary requirements. For some of the factors causing drag, reduction in parasite-drag area may result in increased weight whereas, in other cases, it does not. The final design, however, must be a compromise between the reduction of drag and the increase in weight.

NACA TN 3236

WIND-TUNNEL STUDIES OF THE PERFORMANCE OF MULTIROTOR CONFIGURATIONS. Richard C. Dingeldein. August 1954. 10p. diagrs., photo. (NACA TN 3236)

The power requirements measured in static thrust and in level forward flight are presented for a coaxial and a tandem helicopter rotor configuration. The experimental measurements are compared with the results of calculations based on existing NACA single-rotor theory.

NACA TN 3237

HOVERING PERFORMANCE OF A HELICOPTER ROTOR USING NACA 8-H-12 AIRFOIL SECTIONS. Robert D. Powell, Jr. August 1954. 14p. diagrs., photos. (NACA TN 3237)

A helicopter rotor employing NACA 8-H-12 airfoil sections has been tested on the Langley helicopter test tower. Tests were made for two surface conditions, one within -0.002 inch of true airfoil contour and the other within -0.020 inch. The blades within 0.002 inch of true airfoil contour showed an average decrease of 6 to 7 percent in total torque coefficients.

NACA TN 3238

REVIEW OF INFORMATION ON INDUCED FLOW OF A LIFTING ROTOR. Alfred Gessow. August 1954. 16p. diagrs., photo., tab. (NACA TN 3238)

A brief review of the available information relating to rotor inflow is presented. The available material is summarized in a table as to flight condition, type of information, source, and the reference papers in which the data can be found. Some representative aspects of some of the reference material are discussed.

NACA TN 3239

SOME ASPECTS OF THE HELICOPTER NOISE PROBLEM. Harvey H. Hubbard and Leslie W. Lassiter. August 1954. 14p. diagrs., photo. (NACA TN 3239)

Some aspects of the helicopter noise problem are briefly discussed. These discussions deal with the nature of the problem, some tentative criteria for use in evaluating it, and the physical characteristics of noise from helicopters. Overall noise data are presented for a reciprocating-engine helicopter along with discussions of the characteristics of noise from its various components such as the engine, gearing, and rotors. Some consideration is also given to the noise from tip jet rotor systems.

NACA TN 3241

AIRFOIL SECTION CHARACTERISTICS AT HIGH ANGLES OF ATTACK. Laurence K. Loftin, Jr. August 1954. 10p. diagrs. (NACA TN 3241)

Information from the literature and from recent investigations is used to summarize briefly the effects of airfoil section parameters and flow variables on the aerodynamic characteristics of symmetrical airfoils at high angles of attack. The results indicate that airfoil thickness ratio, Reynolds number, Mach number, and surface roughness can all have an important effect on the maximum lift coefficient. Beyond the stall, changes in section thickness ratio appear to have little effect on the aerodynamic characteristics of airfoil sections.

NACA TN 3244

AERODYNAMIC CHARACTERISTICS OF THE NACA 64-010 AND 0010-1.10 40/1.051 AIRFOIL SECTIONS AT MACH NUMBERS FROM 0.30 TO 0.85 AND REYNOLDS NUMBERS FROM 4.0×10^6 TO 8.0×10^6. Laurence K. Loftin, Jr. August 1954. 17p. diagrs., tab. (NACA TN 3244)

The results of a short two-dimensional investigation to determine the aerodynamic characteristics of the NACA 64-010 and 0010-1.10 40/1.051 airfoil sections are presented. The investigation covered a Mach number range from 0.30 to 0.85 and the corresponding Reynolds number range extended from 4.0×10^6 to 8.0×10^6.

NACA TN 3253

SOME EFFECTS OF EXPOSURE TO EXHAUST-GAS STREAMS ON EMITTANCE AND THERMOELECTRIC POWER OF BARE-WIRE PLATINUM RHODIUM - PLATINUM THERMOCOUPLES. George E. Glawe and Charles E. Shepard. August 1954. 30p. diagrs., photos. (NACA TN 3253)

Thermocouples were exposed to exhaust gases from the combustion of propane, 72-octane gasoline, and JP-4 fuel. Exposure increased the emissivity of the thermocouple wire, which increased its radiation error. Two methods are presented for determining the emittance of the wires. The emissivity of a clean platinum rhodium - platinum thermocouple was approximately 0.2 in the temperature range investigated, while the emittance of an exposed thermocouple coated with exhaust residue was about 0.5. The exposure caused negligible change in the thermoelectric power of the thermocouples.

NACA TN 3254

DETERMINATION OF FLAME TEMPERATURES FROM 2000° TO 3000° K BY MICROWAVE ABSORPTION. Perry W. Kuhns. August 1954. 48p. diagrs., photo., 2 tabs. (NACA TN 3254)

Equations are developed and a procedure is outlined for obtaining flame temperatures from the attenuation of microwaves by temperature-induced free electrons. The electron-molecule collision frequency and the effective ionization potentials of alkali metals are found from the attenuation by a gaseous burner flame in the region 1900° to 2400° K. Temperature data of a liquid-propellent burner flame is presented in the region 2200° to 2900° K.

NACA TN 3257

EFFECTS OF CHEMICALLY ACTIVE ADDITIVES ON BOUNDARY LUBRICATION OF STEEL BY SILICONES. S. F. Murray and Robert L. Johnson. August 1954. 24p. diagrs., photos., tab. (NACA TN 3257)

Conventional chemically active additives and more active compounds such as peroxide were investigated. Conventional additives were not effective, but more active materials such as the peroxide did give effective lubrication. However, all the chemically active-type additives were inferior to the solvent-type additions such as the diesters previously studied.

NACA TN 3258

INVESTIGATION OF MACH NUMBER CHANGES OBTAINED BY DISCHARGING HIGH-PRESSURE PULSE THROUGH WIND TUNNEL OPERATING SUPERSONICALLY. Rudolph C. Haefeli and Harry Bernstein. August 1954. 14p. diagrs., photos., tab. (NACA TN 3258)

A series of tests was performed to obtain an indication of the transient-flow phenomena caused by discharging a chamber of high-pressure gas into a wind tunnel operating supersonically. Two types of gust

were obtained; one had a maximum Mach number with a practically zero time duration whereas the other had a maximum Mach number with a finite time duration depending on the specific geometry. Such a test facility is applicable as a supersonic longitudinal-gust tunnel for producing transient boosts in Mach number.

NACA TN 3259

INVESTIGATION OF NICKEL-ALUMINUM ALLOYS CONTAINING FROM 14 TO 34 PERCENT ALUMINUM. W. A. Maxwell and E. M. Grala. August 1954. 42p. diagrs., photos., 7 tabs. (NACA TN 3259)

Alloys containing the intermetallics NiAl and Ni_3Al were prepared by casting. The melting practice developed was most important for the preparation of sound bodies. Room- and elevated-temperature strengths, ductilities, and susceptabilities to hot-rolling were determined. The 17.5-percent-aluminum alloy had the most outstanding properties and was studied in greatest detail. Creep-rupture strength at 1350° F, impact resistance, thermal shock behavior, oxidation resistance, and effects of thermal treatment on microstructure were determined for the 17.5-percent-aluminum alloy.

NACA TN 3261

A METHOD FOR EVALUATING THE EFFECTS OF DRAG AND INLET PRESSURE RECOVERY ON PROPULSION-SYSTEM PERFORMANCE. Emil J. Kremzier. August 1954. 21p. diagrs. (NACA TN 3261)

A method for evaluating the effects of inlet pressure recovery and drag on propulsion system thrust minus drag performance from consideration of engine over-all "pumping" characteristics is presented for air-breathing engines. The equations and curves presented facilitate the choice of inlet for maximum thrust minus drag. Illustrative examples of the use of the curves are also included.

NACA TN 3284

EXAMINATION OF THE EXISTING DATA ON THE HEAT TRANSFER OF TURBULENT BOUNDARY LAYERS AT SUPERSONIC SPEEDS FROM THE POINT OF VIEW OF REYNOLDS ANALOGY. Alvin Seiff. August 1954. 38p. diagrs., tab. (NACA TN 3284)

Experimental data from six investigations of the heat transferred by a turbulent boundary layer at supersonic speeds are studied to see whether or not they are well represented by the modified Reynolds analogy. The heat-transfer data are compared with the existing data on turbulent skin friction at supersonic speeds as affected by Mach number and wall temperature ratio. The effect of the wall temperature ratio on the data is emphasized.

Forest Products Research Lab. (Gt. Brit.)
RADIO FREQUENCY AND OTHER HEATING PROCESSES. PROGRESS REPORT ELEVEN - APRIL, 1954. AGEING TESTS ON GLUED JOINTS CURED BY RADIO FREQUENCY HEATING.
J. F. S. Carruthers and G. E. Soane. 4p. tab. (Forest Products Research Lab.)

Test specimens of glued beech plywood set by radio frequency glue line heating were tested by applying a splitting tool to each glue line and determining the maximum force required to force apart the laminations. The effect of five glues of the strength of the joints was investigated.

Aeronautical Research Council (Gt. Brit.)
EVAPORATION FROM THE SURFACE OF A BODY IN AN AIRSTREAM (WITH PARTICULAR REFERENCE TO THE CHEMICAL METHOD OF INDICATING BOUNDARY-LAYER TRANSITION). P. R. Owen and A. O. Ormerod. 1954. 42p. diagrs., 8 tabs. (ARC R & M 2875; ARC 14,604. Formerly RAE Aero 2431)

The problem of predicting the rate of transport of a gas from or into the surface of a two-dimensional body in an airstream is discussed. The principle object of the investigation is to provide a means of estimating the time required to obtain an experimental record of boundary-layer transition when a chemical technique is used. The methods evolved should, however, find an application to other forced diffusion phenomena.

A REVIEW OF PORPOISING INSTABILITY OF SEAPLANES. A. G. Smith and H. G. White. 1954. 41p. diagrs., 5 tabs. (ARC R & M 2852; ARC 7741. Formerly MAEE H/Res/173)

A review has been made of the evidence on take-off and landing porpoising instability of seaplanes. The basic types of porpoising and their occurrence have been examined: full-scale results have been correlated with model-scale and theoretical results. Porpoising instability has been divided into three basic types, (a) forebody, (b) forebody-afterbody, and (c) step instability.

SYMMETRIC FLUTTER CHARACTERISTICS OF A HYPOTHETICAL DELTA WING. D. L. Woodcock. 1954. 23p. diagrs. (ARC R & M 2839; ARC 13,378. Formerly RAE Structures 68)

This report considers the flutter characteristics of a hypothetical delta wing. It details the results of quaternary calculations showing the effect on the

reduced critical speed of the shapes and relative natural frequencies of the first two normal modes of the aircraft. From these results the stiffnesses necessary to avoid flutter are deduced for two forms of wing structure. The aerodynamic forces have been obtained by using two-dimensional derivatives multiplied by the cosine of the quarter-chord sweepback in conjunction with strip theory applied to fore-and-aft strips. This procedure is of doubtful validity for the low aspect-ratio wing considered. With this reservation, however, the results confirm the adequacy of the present Ministry of Supply wing-stiffness requirement.

CHANGES IN CONTROL CHARACTERISTICS WITH CHANGES IN FLOW PATTERN AT HIGH SUBSONIC SPEEDS. TEST ON AN EC.1250 AEROFOIL WITH 25 PER CENT CONCAVE CONTROL FLAP, PARTS I AND II. R. A. Shaw. 1954. 32p. diagrs., photos., tab. (ARC R & M 2436. Formerly ARC 11,933; FM 1310; S & C 2264; 0.812; ARC 12,284)

This report describes results obtained in wind-tunnel tests where it was found that considerable changes in flow pattern and pressure distribution around an airfoil with control flap occurred in certain conditions for a small increase in speed or change in incidence or control angle. The changes were found first between M = 0.85 and 0.87, when the shock-stalled flow, which had developed at lower speeds, was replaced, on one surface only, by streamline flow extending almost to the trailing edge.

NOTES ON THE DYNAMIC RESPONSE OF AN AIRCRAFT TO GUSTS AND ON THE VARIATION OF GUST VELOCITY ALONG THE FLIGHT PATH WITH SPECIAL REFERENCE TO MEASUREMENTS IN LANCASTER P.D.119. Anne Burns. 1954. 18p. diagrs. (ARC R & M 2759; ARC 12,797. Formerly RAE Structures 47)

A collection of records showing the time histories of strains and accelerations at various parts of a Lancaster flying in clear turbulent air is presented and discussed. The records include specimens taken in cloud at moderate altitudes and in clear air at low altitudes. The amount of oscillation (fundamental) excited by a gust appears to be affected by the variation of gust velocity across the span and the amount of oscillation excited does not appear to show any marked decrease as the airspeed of the aircraft is increased.

AILERON REVERSAL AND WING DIVERGENCE OF SWEPT WINGS. E. G. Broadbent and Ola Mansfield. 1954. 26p. diagrs., 6 tabs. (ARC R & M 2817; ARC 11,148. Formerly RAE Structures 9)

A method of solution for the aileron reversal speed of a swept wing (with emphasis on sweepback) is developed on the lines of strip and semirigid theories. The influence of the degree of sweep, wing torsional and flexural stiffness, wing plan form, and aileron plan form is investigated. Families of curves are given for extended variation of these parameters which may be used for the direct estimation of the reversal speed of a given wing by interpolation. A solution is given for the wing divergence speed of a swept wing.

NOTES ON THE INDUCED DRAG OF A WIND-TAIL COMBINATION. C. H. Naylor. 1954. 10p. diagrs., tab. (ARC R & M 2528. Formerly ARC 9974; Perf. 223)

An expression has been derived for the factor to be applied to ideal induced drag to allow for wing-tail interference. This factor is primarily dependent on the wing-tail lift and span ratios. It is of the order of 1:1 for a normal aircraft when the tailplane carries 10 percent of the weight of the aircraft, and can reach unexpectedly large values of high speed. Charts, generalized curves, and sufficient information are included to permit rapid evaluation of the factor for any particular case.

WING PARACHUTES FOR RECOVERY FROM THE SPIN. PART I - GENERAL DESIGN REQUIREMENTS. G. E. Pringle and T. V. Somerville. PART II - WAKE PHENOMENA. D. J. Harper, J. R. Mitchell, J. Picken and G. E. Pringle. 1954. 10p. diagrs., tab. (ARC R & M 2543; ARC 8388; ARC 10,762. Formerly RAE Tech. Note Aero 1559; Tech. Note Aero 1881)

The wing parachutes of a tailless aircraft prototype failed to open when streamed in an accidental spin. This gave a clue to the existence of a marked wake effect when a parachute is deployed on a tow cable behind a stalled wing. The wake effect is such as to reduce the critical closing speed of the parachute. The effect measured in a wind tunnel diminishes as the cable is lengthened. It is recommended that the cables be made as long as possible up to 1-1/2 spans in length; here the danger of entanglement becomes real.

FURTHER EXPERIMENTS ON AN NACA 23021 AEROFOIL WITH A 15 PER CENT HANDLEY PAGE SLOTTED FLAP IN THE COMPRESSED AIR TUNNEL. R. Jones and A. H. Bell. 1954. 16p. diagrs., 6 tabs. (ARC R & M 2519. Formerly ARC 9864; Perf.206 S & C 2041)

The NACA 23021 airfoil was tested with a form of flap and slot which was modified by a rounding-off of the trailing edge of the main wing on the lower surface and of the leading edge of the flap, thus making the gap on the lower surface appreciably larger. The model was tested at R = 0.75 to 7.1×10^6 over the usual incidence range with flap

settings of 0° to 80°. The results are very similar to those obtained on an earlier model. An overall check of apparatus and model was obtained by closing the gap at 60° flap angle and repeating with satisfactory results some of the tests on the original model.

STATIONARY RIG EXPERIMENTS ON THE HEAT EXTRACTING POWER OF CLOSED THERMOSYPHON COOLING HOLES. H. W. Hahnemann. 1954. 44p. diagrs., tab. (ARC CP 152)

Information is given on heat flow in closed sodium-filled holes in turbine blades. The rig was a tube filled with fluid, transferring heat upwards by free convection from an electrically heated lower section to a water cooled upper section. The high Grashof numbers obtained in closed thermosyphon holes in actual turbine blades were approached by using tubes of large diameter, and measurements were made with mercury, water, and oil as the heat transporting fluid in order to cover a wide range of Grashof and Prandtl numbers. A formula correlating the results for the three different fluids was obtained.

THE INFLUENCE OF SURFACE WAVES ON THE STABILITY OF A LAMINAR BOUNDARY LAYER WITH UNIFORM SUCTION. D. A. Spence and D. G. Randall. 1954. 29p. diagrs. (ARC CP 161)

In order to estimate the destabilizing effect of waves likely to be encountered on wing surfaces which will be used with boundary layer suction, calculations have been made of the effect of small sinusoidal surface waves on the stability of the asymptotic suction profile. Curves are presented of the percentage increases in local suction flow, necessary to maintain the stability of the boundary layer at the same level as on a completely flat surface for various values of local suction flow, height: wave length ratio, and Reynolds number based on wave length. It is found that for the lower local suction flow or the larger height: wave length ratio the larger the necessary percentage increase in local suction flow.

THE MEASUREMENT OF POSITION ERROR AT HIGH SPEEDS AND ALTITUDE BY MEANS OF A TRAILING STATIC HEAD. K. W. Smith. 1954. 34p. diagrs., photo. (ARC CP 160)

The static position error of a service wing-tip leading edge pressure head installation has been measured on a Meteor VII by means of a trailing static head, developed especially for use at high speeds. These tests cover an altitude range from zero to 38,000 ft, and include measurements in "g" turns. The maximum Mach number reached was 0.84. For comparative purposes the static error was also measured at ground level by the aneroid method.

CALIBRATION OF THE R. A. E. NO. 18 (9 IN. x 9 IN.) SUPERSONIC WIND TUNNEL. PART I - PRELIMINARY INVESTIGATIONS. W. T. Lord and D. Beastall. 1954. 44p. diagrs., 6 tabs. (ARC CP 162)

A detailed account is given of the investigations performed in the RAE No. 18 (9-inch by 9-inch, continuous flow, variable density) supersonic wind tunnel prior to an extensive calibration of the tunnel. Variables which have an important effect on the behavior of the flow are discussed, and preliminary experiments to determine their significance are described. Results of the investigations serve to define the course of the complete calibration, and may provide a useful guide to future calibrations of similar supersonic tunnels. The calibration program is outlined: Part II will deal with tests at atmospheric stagnation pressure, and further tests at various stagnation pressures are proposed.

CALIBRATION OF THE R. A. E. NO. 18 (9 IN. x 9 IN.) SUPERSONIC WIND TUNNEL. PART II - TESTS AT ATMOSPHERIC STAGNATION PRESSURE. W. T. Lord, G. K. Hunt, R. J. Pallant and J. Turner. 1954. 24p. diagrs., 3 tabs. (ARC CP 163)

This report presents distributions of Mach number in the empty working section of the R. A. E. No. 18 (9-inch by 9-inch) supersonic wind tunnel at nominal Mach numbers of 1.4, 1.5, 1.6, 1.8, and 1.9, for condensation-free flow at atmospheric stagnation pressure and at a stagnation temperature of 35°. The major contributions to the nonuniformity of the flow are from the disturbances which arise from the junctions of the windows with the side walls of the tunnel. An indication of the boundaries of the working section for each Mach number is given.

TABULATION OF THE BLASIUS FUNCTION WITH BLOWING AND SUCTION. H. W. Emmons and D. C. Leigh. 1954. 81p. diagrs., 3 tabs. (ARC CP 157)

The present solutions cover the whole possible range of blowing and suction values. It was in connection with the solution of a combustion problem that the present solutions were obtained. Previous

calculations were given to four decimal places. These hand computed tables generally agree to better than 5 in the last place with the present one. Calculations were done on the Electronic Delay Storage Automatic Calculator.

EFFECTS OF ROUGHNESS AND SUCTION ON TRANSITION FROM LAMINAR TO TURBULENT FLOW. Hugh L. Dryden. 12p. diagrs. (Reprint from Mémoires sur la Mécanique des Fluides, Ministére de l'Air, Publications Scientifiques et Techniques, p. 49-60, 1954)

The effect of roughness in reducing the gains attainable through the use of suction is described. Boundary layer stability, theoretical results for boundary-layer suction, effects of roughness on transition, experimental data on the effect of suction on transition, and combined effects of roughness and suction are topics included. It is concluded that only an extensive program carefully planned in the light of our present knowledge of roughness effects can settle the question as to whether the theoretically predicted stabilization of the flow can be obtained in practice.

Univ. of Minn., Institute of Technology. THERMAL STRESSES IN BOX BEAMS - A THEORETICAL AND EXPERIMENTAL STUDY OF STRESSES IN ALUMINUM ALLOY BOX SECTIONS UNDER GIVEN TEMPERATURE DISTRIBUTIONS. Joseph A. Wise and Paul Andersen. January 1954. 130p. diagrs., photos. (Univ. of Minn., Institute of Technology)

A theoretical and experimental study of stresses in thin shell box sections due to thermal gradients is presented. The basic theory is first developed for plate-like sections then for box sections. Three specimens were tested in an attempt to verify the theory. It was concluded that the basic theory has received some support from these tests, but much more extended research is necessary to establish it completely.

NACA RM A7J05

WIND-TUNNEL INVESTIGATION AT A MACH NUMBER OF 1.53 OF AN AIRPLANE WITH A TRIANGULAR WING. Richard Scherrer and William R. Wimbrow. January 23, 1948. 74p. diagrs., photos., 2 tabs. (NACA RM A7J05) (Declassified from Confidential, 8/18/54)

Models of a tailless pursuit-type supersonic airplane were tested in the Ames 1- by 3-foot supersonic wind tunnel No. 1. The basic configuration and several modifications were tested in pitch and yaw and with deflections of the constant-chord control surfaces. The control effectiveness was found to be independent of angle of attack and was found to vary linearly with control deflection. The variation of drag with lift was small. All of the configurations tested were longitudinally stable, but most were directionally unstable.

NACA RM E8F07

DESIGN AND PERFORMANCE OF EXPERIMENTAL AXIAL-DISCHARGE MIXED-FLOW COMPRESSOR. II - PERFORMANCE OF IMPELLER. Ward W. Wilcox. August 12, 1948. 21p. diagrs., photo. (NACA RM E8F07) (Declassified from Confidential, 8/18/54)

Results are presented of preliminary tests on an axial-discharge mixed-flow impeller that was designed to combine the compactness, reliability, and wide operating range of mixed-flow compressor with high flow capacity per unit of frontal area that characterizes the axial-flow compressors. At design tip speed of 1480 feet per second, maximum flow capacity of 18.7 pounds per second, peak adiabatic efficiency of 0.78, and peak total-pressure ratio of 3.7 were obtained. Flow capacity per unit of frontal area for this axial discharge impeller is much greater than that of current commercial mixed-flow compressors but is somewhat less than that for the axial-flow compressors having the highest flow capacity per unit frontal area.

NACA RM L7I04

PRELIMINARY TANK TESTS OF NACA HYDRO-SKIS FOR HIGH-SPEED AIRPLANES. John R. Dawson and Kenneth L. Wadlin. November 26, 1947. 19p. diagrs., photos. (NACA RM L7I04) (Declassified from Confidential, 8/18/54)

Contains results from tank landings and take-off tests with a dynamic model of a hypothetical jet-propelled airplane equipped with NACA hydro-skis. These results show stable take-offs and landings for the model, although the resistance is high. The resistance, which is not considered necessarily inherent, appears to be acceptable for airplanes equipped with rocket motors. It is concluded that hydro-skis suitable for flush retraction into streamline fuselages offer a practicable means for taking off and landing high-speed airplanes on the water.

NACA RM L7K14

FLIGHT TESTS TO DETERMINE THE EFFECT OF AIRFOIL SECTION PROFILE AND THICKNESS RATIO ON THE ZERO-LIFT DRAG OF LOW-ASPECT-RATIO WINGS AT SUPERSONIC SPEEDS. Ellis Katz. February 9, 1948. 19p. diagrs., photos. (NACA RM L7K14) (Declassified from Confidential, 8/18/54)

Experimental determination of the zero-lift drag at low supersonic speeds of low-aspect-ratio wings with: (1) nonswept round-nose sections having varying degrees of thickness ratio from 0.03 to 0.09 and (2) swept and nonswept wings having round-nose, circular-arc, and diamond sections of 0.09 thickness ratio.

NACA RM L7K24

HIGH-SPEED WIND-TUNNEL TESTS OF A 1/16-SCALE MODEL OF THE D-558 RESEARCH AIRPLANE. BASIC LONGITUDINAL STABILITY OF THE D-558-1. John B. Wright. May 12, 1948. 19p. diagrs., tab. (NACA RM L7K24) (Declassified from Confidential, 8/18/54)

This report contains the results of pitching-moment, lift, and drag measurements with a 1/16-scale model of the D-558-1, with no nose-inlet flow, with both the tail removed and with the tail at a constant setting. The tests were conducted through a Mach number range up to 0.96 in the Langley 8-foot high-speed tunnel. Only a limited analysis has been made. It is indicated that the airplane can experience large changes in static longitudinal stability beyond a Mach number of 0.86. At a Mach number of 0.9 there is a tendency for the airplane to become unstable at low lift coefficients followed by large stable tendency at higher speeds. A part of this change in stability is indicated to be destabilizing effects from wing-fuselage characteristics.

NACA RM L8A05

FLIGHT TESTS TO DETERMINE THE DRAG OF FIN-STABILIZED PARABOLIC BODIES AT TRANSONIC AND SUPERSONIC SPEEDS. Sidney R. Alexander, Leo T. Chauvin and Charles B. Rumsey. April 21, 1948. 24p. diagrs., photos. (NACA RM L8A05) (Declassified from Confidential, 8/18/54)

Two fin-stabilized parabolic bodies of revolution of fineness ratios 7.87 and 12 were flight tested over the transonic and supersonic range. Curves of measured total drag coefficient plotted against Mach number are presented together with estimates of total drag coefficient for several Mach numbers to indicate the reasonable accuracy that can be expected from such predictions. The tests also proved the effectiveness of a simple "drag-separation" type booster arrangement.

NACA RM L8A07

FREE-FLIGHT INVESTIGATION OF THE ROLLING EFFECTIVENESS OF A WING-SPOILER ARRANGEMENT AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS. Carl A. Sandahl. May 17, 1948. 10p. diagrs., photo. (NACA RM L8A07) (Declassified from Confidential, 8/18/54)

An investigation of the rolling effectiveness of a wing-spoiler arrangement has been conducted by the use of rocket-propelled test vehicles in free flight. The results obtained for the configuration tested, which probably was not an optimum, indicated that rolling effectiveness was a maximum at about $M = 0.91$, decreased abruptly in the Mach number range from 0.92 to about 1.0, and continued to decrease with increasing Mach number to the maximum attained ($M = 1.73$).

NACA RM L8A12

FORCE, STATIC LONGITUDINAL STABILITY, AND CONTROL CHARACTERISTICS OF A 1/16-SCALE MODEL OF THE BELL XS-1 TRANSONIC RESEARCH AIRPLANE AT HIGH MACH NUMBERS. Axel T. Mattson and Donald L. Loving. June 23, 1948. 49p. diagrs., tab. (NACA RM L8A12) (Declassified from Confidential, 8/18/54)

This report contains results obtained to determine the effects of compressibility at high Mach numbers on a 1/16-scale model of the Bell XS-1 transonic research airplane. These results are presented for several model configurations through a Mach number range from 0.4 to approximately 0.925. Presented in the report are the lift, drag, and pitching-moment variations with Mach numbers for angles of attack of 0° and 3° for various stabilizer incidences and elevator deflections. The incremental drag, lift, and pitching-moment characteristics are presented for a fuselage speed retarder.

NACA RM L8A22

QUALITATIVE MEASUREMENTS OF RELATIVE FLAP EFFECTIVENESS AT TRANSONIC SPEEDS ON A SERIES OF FIVE THIN AIRFOILS WITH 25-PERCENT-CHORD FLAPS AND VARIOUS AMOUNTS OF SWEEPBACK. Harold L. Crane and Milton D. McLaughlin. May 17, 1948. 24p. diagrs., photos. (NACA RM L8A22) (Declassified from Confidential, 8/18/54)

Tests were made by the wing-flow method on a series of 3-percent-thick models which had sweepback combinations of leading edge and flap hinge line ranging from 0° to 45°. Full-span flaps were tested in all

cases, and, in addition, a half-span flap was tested on a 45° sweptback model. The Mach number range was from 0.5 to 1.1, and at M = 0.8 the Reynolds number range was approximately 700,000 to 1,500,000. The tests showed that the sweptback flaps were less effective but had a smaller decrease in effectiveness with speed. In no case was there an abrupt change in effectiveness or a complete loss of or reversal of effectiveness.

NACA RM L8A28

CURRENT STATUS OF LONGITUDINAL STABILITY. Charles J. Donlan. May 24, 1948. 16p. diagrs. (NACA RM L8A28) (Declassified from Confidential, 8/18/54)

The problems of static and dynamic longitudinal stability both at high speeds and at low speeds are discussed and data are presented which indicate recent progress made in the solution of these problems.

NACA RM L8A28b

DRAG MEASUREMENTS AT TRANSONIC SPEEDS OF TWO BODIES OF FINENESS RATIO 9 WITH DIFFERENT LOCATIONS OF MAXIMUM BODY DIAMETER. Jim Rogers Thompson and Max C. Kurbjun. July 22, 1948. 17p. diagrs., photos. (NACA RM L8A28b) (Declassified from Confidential, 8/18/54)

Contains total drag measurements by the free-fall method for two bodies of fineness ratio 9 with the maximum diameter located 16.7 percent ahead of and behind the body midpoint. The results are compared with those of previous tests to show the effect of location of maximum body diameter on drag between Mach numbers of 0.85 to 1.08 and to provide some information on the mechanism of the abrupt drag rise which occurs between Mach numbers of 0.95 and 1.00.

NACA RM L8A28e

LANDING CHARACTERISTICS OF HIGH-SPEED WINGS. Herbert A. Wilson, Jr. and Laurence K. Loftin, Jr. September 21, 1948. 21p. diagrs. (NACA RM L8A28e) (Declassified from Confidential, 8/18/54)

The results of investigations of the maximum lift characteristics of wings for airplanes designed to fly at transonic Mach numbers are summarized. It is concluded that maximum lift coefficients of about 1.3 to 1.6 can be obtained for wings of this type with the high-lift devices investigated, leading-edge flaps improve the characteristics of the wings, and the drag at high lifts is of importance in determining the landing characteristics.

NACA RM L8B03

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A SEMISPAN AIRPLANE MODEL AT TRANSONIC SPEEDS AS OBTAINED BY THE TRANSONIC-BUMP METHOD. Joseph Weil and M. Leroy Spearman. July 19, 1948. 23p. diagrs., tab. (NACA RM L8B03) (Declassified from Confidential, 8/18/54)

Tests were made using the transonic-bump method to determine the longitudinal stability and control characteristics in the transonic range of a semispan airplane model similar to a proposed research vehicle. A comparison was made with results obtained for the same model by the NACA wing-flow method. The model was mounted on a pivot and was free to trim at zero pitching moment. The lift coefficient and angle of attack for trim at various stabilizer settings were obtained for four center-of-gravity positions. The tests were made through a Mach number range from 0.60 to 1.20.

NACA RM L8B06

HIGH-SPEED WIND-TUNNEL TESTS OF A 1/16-SCALE MODEL OF THE D-558 RESEARCH AIRPLANE. D-558-1 SPEED-REDUCTION BRAKE AND SYMMETRICAL-PROFILE WING CHARACTERISTICS. John B. Wright. June 15, 1948. 22p. diagrs., tab. (NACA RM L8B06) (Declassified from Confidential, 8/18/54)

Contains a limited analysis of the results of pitching-moment, lift, and drag measurements with a 1/16-scale model of the D-558-1 through a Mach number range up to 0.96 in the Langley 8-foot high-speed tunnel. Tests of the model were made with speed-reduction brakes on the fuselage sides fully deflected. Tests were also made with the model (without brakes) utilizing a wing of symmetrical profile. Included for comparison are data for the model without the brakes and for the model with a cambered wing.

NACA RM L8B18

TANK SPRAY TESTS OF A JET-POWERED MODEL FITTED WITH NACA HYDRO-SKIS. Kenneth L. Wadlin and John A. Ramsen. July 22, 1948. 19p. diagrs., photos. (NACA RM L8B18) (Declassified from Confidential, 8/18/54)

Contains tank results of take-off tests with a powered dynamic model of a hypothetical jet-propelled high-speed airplane, fitted with NACA hydro-skis, and having flush turbojet intakes on the upper part of the fuselage near the nose. It was concluded that take-offs can be made without spray entering the intakes by using very small longitudinal strips. The tendency of the turbojet air inflow to draw spray into the intakes is slight. Jet power increased trims during the high-speed part of the take-off run.

NACA RM L8B19

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A SEMISPAN AIRPLANE MODEL WITH A SWEPTBACK WING AND TAIL FROM TESTS AT TRANSONIC SPEEDS BY THE NACA WING-FLOW METHOD. Richard H. Sawyer and Lindsay J. Lina. July 23, 1948. 42p. diagrs., photos., tab. (NACA RM L8B19) (Declassified from Confidential, 8/18/54)

The angle of attack and lift coefficient obtained under trimmed (zero pitching-moment) conditions with fixed controls are presented for Mach numbers from 0.50 to 1.07 for a semispan airplane model having a 45° sweptback wing and tail. The effects of

Reynolds number and the effectiveness of a wing flap similar to a dive-recovery flap on a straight wing also were investigated briefly. Comparison is made with previous tests of the model equipped with, first, an unswept wing and tail and, second, with an unswept wing and sweptback tail.

NACA RM L8B26

PRELIMINARY FREE-FLIGHT INVESTIGATION OF THE EFFECT OF AIRFOIL SECTION ON AILERON ROLLING EFFECTIVENESS AT TRANSONIC AND SUPERSONIC SPEEDS. Carl A. Sandahl. June 25, 1948. 6p. diagrs. (NACA RM L8B26) (Declassified from Confidential, 8/18/54)

Results have been obtained by means of a free-flight technique utilizing rocket propulsion which indicate that aileron-rolling-effectiveness characteristics are affected adversely by variations in airfoil section which produce large increases in the trailing-edge angle.

NACA RM L8C23

HIGH-SPEED WIND-TUNNEL TESTS OF A 1/16-SCALE MODEL OF THE D-558 RESEARCH AIRPLANE. LONGITUDINAL STABILITY AND CONTROL OF THE D-558-1. John B. Wright. July 8, 1948. 47p. diagrs., tab. (NACA RM L8C23) (Declassified from Confidential, 8/18/54)

This paper contains the results of pitching-moment and lift measurements with a 1/16-scale model of the D-558-1, with no nose-inlet flow, and at several stabilizer and elevator settings. The tests were conducted up to a Mach number of 0.96 in the Langley 8-foot high-speed tunnel. Only a limited analysis of the various stability and control parameters is presented.

NACA RM L8C25

AERODYNAMIC LOSSES IN LOW-PRESSURE TAILPIPE EXHAUST DUCTS FOR ROCKET-PROPELLED AIRCRAFT. W. K. Hagginbothom and J. G. Thibodaux. July 20, 1948. 15p. diagrs., photos. (NACA RM L8C25) (Declassified from Confidential, 8/18/54)

An evaluation of the aerodynamic losses involved in the use of exhaust ducts for rocket-propelled aircraft was obtained from thrust stand tests. The aerodynamic losses created by the use of low-pressure tailpipe exhaust ducts for rocket-propelled aircraft are within practical limits insofar as overall propulsion requirements for pilotless-aircraft models are concerned.

NACA RM L8D21

PRELIMINARY INVESTIGATION OF VARIOUS AILERONS ON A 42° SWEPTBACK WING FOR LATERAL CONTROL AT TRANSONIC SPEEDS. Thomas R. Turner, Vernard E. Lockwood and Raymond D. Vogler. September 7, 1948. 35p. diagrs., photo. (NACA RM L8D21) (Declassified from Confidential, 8/18/54)

Contains the rolling-moment characteristics for a reflection-plane model with 42.8° leading-edge sweep, aspect ratio 4.0, and taper ratio 0.50 for several aileron configurations (chord and contour change) in the transonic speed range. The paper also includes some rolling-moment characteristics for spoilers, wing-tip aileron, and leading-edge flaps through the transonic speed range at Mach numbers from 0.5 to 1.15.

NACA RM L8E14

LIMITED MEASUREMENTS OF STATIC LONGITUDINAL STABILITY IN FLIGHT OF DOUGLAS D-558-1 AIRPLANE (BUAERO NO. 37971). Walter C. Williams. June 24, 1948. 10p. diagrs., photos., tab. (NACA RM L8E14) (Declassified from Confidential, 8/18/54)

Contains a few measurements of the variation of elevator angle and elevator force with Mach number at 30,000 feet altitude up to a Mach number of 0.85. These data show that the airplane possessed positive static longitudinal stability up to a Mach number of 0.80. A trim change in the nose-down direction occurred for Mach numbers above 0.82.

NACA RM L8E14a

FLIGHT MEASUREMENT OF THE STABILITY CHARACTERISTICS OF THE DOUGLAS D-558-1 AIRPLANE (BUAERO NO. 37971) IN SIDESLIPS. Walter C. Williams. April 18, 1949. 23p. diagrs., photos. (NACA RM L8E14a) (Declassified from Confidential, 8/18/54)

Measurements have been made of the stability characteristics of the D-558-1 airplane in steadily increasing sideslips at various Mach numbers from 0.50 to 0.80 at 10,000 feet altitude and at Mach numbers from 0.50 to 0.84 at 30,000 feet altitude. The results of these tests show that the apparent directional stability of the airplane is high and increases with increasing Mach number and dynamic pressure. The dihedral effect is positive at all speeds, there is little or no change in pitching moment with sideslip, and the cross-wind force is positive.

NACA RM L8E27

FLIGHT TESTS OF A TWO-DIMENSIONAL WEDGE DIFFUSER AT TRANSONIC AND SUPERSONIC SPEEDS. M. A. Faget. August 11, 1948. 21p. diagrs., photos. (NACA RM L8E27) (Declassified from Confidential, 8/18/54)

A two-dimensional wedge diffuser suitable for use in a ducted-airfoil ram jet was flight tested. Test results at flight speeds from $M = 0.7$ to $M = 1.4$ are presented. A velocity survey at the exit of the diffuser showed a large wake effect from the island which was faired behind the central wedge. Curves showing diffuser-exit Mach numbers, velocity, pressure, and mass flow are all smooth throughout the transonic region indicating the diffusion process to be fairly insensitive to passage through the transonic region.

NACA RM L8F24

APPLICATION OF ONE PART OF VON KARMAN'S TWO-DIMENSIONAL TRANSONIC SIMILARITY LAW TO DRAG DATA OF NACA 65-SERIES WINGS. Kenneth B. Amer. August 24, 1948. 9p. diagrs. (NACA RM L8F24) (Declassified from Confidential, 8/18/54)

Application of one part of Von Kármán's two-dimensional transonic similarity law to drag data of wings having NACA 65-006, 65-009, and 65_1-012 profiles and aspect ratios of 7.6 in the transonic range shows satisfactory correlation. The presence of various factors in the flow which were not considered in the derivation of the law from the potential flow equation did not appreciably affect the degree of correlation.

NACA RM L8G29a

DETERMINATION BY THE FREE-FALL METHOD OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 1/4-SCALE MODEL OF THE BELL XS-1 AIRPLANE AT TRANSONIC SPEEDS. James T. Matthews, Jr. and Charles W. Mathews. November 9, 1948. 19p. diagrs., photo., tab. (NACA RM L8G29a) (Declassified from Confidential, 8/18/54)

Report presents results of a free-fall test to determine longitudinal stability and control characteristics of a 1/4-scale model of the Bell XS-1 airplane. The model attained a Mach number of 0.98. Time histories given show variations of elevator position, normal and transverse accelerations, longitudinal retardation, and Mach number throughout the fall. Variations with Mach number of lift coefficient, drag coefficient, and lift-to-drag ratio are also presented. Observations on and explanations of the behavior of the model are included.

NACA RM L8G30

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A SEMISPAN MODEL OF A SUPERSONIC AIRPLANE CONFIGURATION AT TRANSONIC SPEEDS FROM TESTS BY THE NACA WING-FLOW METHOD. Norman S. Silsby and James M. McKay. November 8, 1948. 30p. diagrs., photos., tab. (NACA RM L8G30) (Declassified from Confidential, 8/18/54)

The investigation was made by the NACA wing-flow method of the longitudinal stability and control characteristics in the transonic range of a semispan model of a supersonic airplane configuration having a long slender fuselage and straight wing and tail with faired double-wedge airfoil sections 4.6 percent thick, aspect ratio 4.0, and taper ratio 2.

NACA RM L8H05

HIGH-SPEED WIND-TUNNEL TESTS OF A 1/16-SCALE MODEL OF THE D-558 RESEARCH AIRPLANE - DYNAMIC PRESSURE AND COMPARISON OF POINT AND EFFECTIVE DOWNWASH AT THE TAIL OF THE D-558-1. Harold L. Robinson. November 4, 1948. 27p. diagrs. (NACA RM L8H05) (Declassified from Confidential, 8/18/54)

The results indicate that the downwash changes that occur at the tail location of the D-558-1 airplane are not the cause for the instability reported in previous papers. The tests include a Mach number range of 0.40 to 0.94 and a lift-coefficient range of -0.3 to 0.7. The rate of change of point downwash with lift coefficient decreases at high speeds and low lift coefficient, thus causing a stabilizing effect. The appendices of this paper give a method of correlating stability with downwash and also give a method of including tail drag when measuring downwash by the tail-on and tail-off methods.

NACA RM L8H06a

EFFECT OF DOWNWASH ON THE ESTIMATED ELEVATOR DEFLECTION REQUIRED FOR TRIM OF THE XS-1 AIRPLANE AT SUPERSONIC SPEEDS. James T. Matthews, Jr. November 1, 1948. 11p. diagrs. (NACA RM L8H06a) (Declassified from Confidential, 8/18/54)

Contains estimation of elevator deflections required for trim at supersonic speeds of the XS-1 including the effect of downwash determined from linearized theory. Results indicate that increasing up-elevator deflection is required in level flight as the Mach number increases from 1.1 to about 1.6 with a slight reduction of up elevator occurring between 1.6 and 2.0. The reasons for these trends have been analyzed and are presented in the paper.

NACA RM L8I23

ADDITIONAL FREE-FLIGHT TESTS OF THE ROLLING EFFECTIVENESS OF SEVERAL WING-SPOILER ARRANGEMENTS AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS. H. Kurt Strass. November 24, 1948. 16p. diagrs., photos. (NACA RM L8I23) (Declassified from Confidential, 8/18/54)

Additional results of an aerodynamic-control-effectiveness investigation using free-flight, rocket-propelled test vehicles have been obtained recently which show some results of chordwise spoiler location and a comparison of a sharp-edge spoiler with a wedge-type spoiler at the 0.8-chord location and a plain, full-span, 0.2-chord aileron with a deflection equal to 4.4°.

NACA RM L8J21

THE EFFECT OF AIR JETS SIMULATING CHINES OR MULTIPLE STEPS ON THE HYDRODYNAMIC CHARACTERISTICS OF A STREAMLINE FUSELAGE. Bernard Weinflash. January 7, 1949. 37p. diagrs., photos., 2 tabs. (NACA RM L8J21) (Declassified from Confidential, 8/18/54)

Preliminary tests were made to determine the effect of forced ventilation on the hydrodynamic characteristics of a streamline fuselage of a hypothetical transonic airplane. This forced ventilation consisted of air ejected at about 300 feet per second through small orifices distributed over the fuselage bottom in various patterns simulating chines and/or multiple steps. Data are presented on the resistance, trim, and effective hydrodynamic lift for the basic model and **for**

each of the jet configurations. All of the jet configurations caused appreciable improvement in hydrodynamic performance, especially at higher speeds.

NACA RM L8K01

EFFECT OF WING SWEEP, TAPER, AND THICKNESS RATIO ON THE TRANSONIC DRAG CHARACTERISTICS OF WING-BODY COMBINATIONS. Jim Rogers Thompson and Charles W. Mathews. December 31, 1948. 29p. diagrs., photos., 2 tabs. (NACA RM L8K01) (Declassified from Confidential, 8/18/54)

Contains free-fall measurements of the transonic drag characteristics of three wing-body combinations having 35° sweptback wings with thickness ratios of 0.09 and 0.12 and taper ratios of 1:1 and 1.467:1. Results are compared with measurements for four related configurations reported previously and with theoretical calculations to show the effects of wing sweep, taper, and thickness ratio on the transonic drag characteristics of wing-body combinations and their component parts.

NACA RM L8K02

AERODYNAMIC CHARACTERISTICS AT SUBSONIC AND TRANSONIC SPEEDS OF A 42.7° SWEPTBACK WING MODEL HAVING AN AILERON WITH FINITE TRAILING-EDGE THICKNESS. Thomas R. Turner, Vernard E. Lockwood and Raymond D. Vogler. January 12, 1949. 24p. diagrs., photo. (NACA RM L8K02) (Declassified from Confidential, 8/18/54)

This paper contains the aerodynamic characteristics for a reflection-plane model having 42.7° leading-edge sweep, an aspect ratio of 4.0, and a taper ratio of 0.50 with an aileron of various finite trailing-edge thicknesses. The aerodynamic characteristics which include aileron rolling moments were obtained through the transonic-speed range from a Mach number of 0.5 to 1.15. The tests were performed in transonic flow over a bump on the tunnel floor and in subsonic flow on one of the tunnel side walls.

NACA RM L8K03

STABILITY RESULTS OBTAINED WITH DOUGLAS D-558-1 AIRPLANE (BUAERO NO. 37971) IN FLIGHT UP TO A MACH NUMBER OF 0.89. William H. Barlow and Howard C. Lilly. April 22, 1949. 16p. diagrs., photos. (NACA RM L8K03) (Declassified from Confidential, 8/18/54)

Contains flight measurements of trim characteristics in straight flight for two stabilizer settings for D-558-1 airplane up to a Mach number of 0.89. Also shows elevator angle per unit normal-force coefficient and elevator control force per unit acceleration up to a Mach number of 0.82. The buffet boundary is well defined up to a Mach number of 0.84 and is shown in comparison with that of the XS-1 airplane with the same wing section, 65-110.

NACA RM L8K23a

THEORETICAL ANALYSIS OF THE ROLLING MOTIONS OF AIRCRAFT USING A FLICKER-TYPE AUTOMATIC ROLL STABILIZATION SYSTEM HAVING A DISPLACEMENT-PLUS-RATE RESPONSE. Howard J. Curfman, Jr. January 12, 1949. 29p. diagrs., 2 tabs. (NACA RM L8K23a) (Declassified from Confidential, 8/18/54)

A general analysis of the steady-state rolling oscillations of aircraft using the displacement-plus-rate response, flicker-type automatic roll stabilization system is presented, and charts are included for finding the amplitude and period of these oscillations for any aircraft. The addition of the rate-sensitive element to the displacement-response, flicker-type system reduces the amplitude and increases the frequency of the steady-state oscillations. Current trends in pilotless-aircraft designs indicate that small amplitude residual oscillations are possible. The analysis shows close agreement with roll-simulator tests.

NACA RM L8K29

AN INVESTIGATION OF AILERON OSCILLATIONS AT TRANSONIC SPEEDS ON NACA 23012 AND NACA 65-212 AIRFOILS BY THE WING-FLOW METHOD. Harold L. Crane. December 29, 1948. 9p. diagrs., photo. (NACA RM L8K29) (Declassified from Confidential, 8/18/54)

An investigation is being conducted to determine the feasibility of studying aileron buzz by means of the wing-flow method. Two semispan models which had an aspect ratio of 6 and a taper ratio of 2 with quarter-chord half-span mass-balanced ailerons have been used. One had an NACA 23012 airfoil section and the second, an NACA 65-212 airfoil section. The ailerons on both models were subject to buzz over a small range of Mach number near 0.9. Data obtained by wing-flow testing agreed reasonably well with full-scale flight results.

NACA RM L8L07

ESTIMATION OF LIFT AND DRAG OF AIRFOILS AT NEAR SONIC SPEEDS AND IN THE PRESENCE OF DETACHED SHOCK WAVES. John P. Mayer. February 23, 1949. 23p. diagrs. (NACA RM L8L07) (Declassified from Confidential, 8/18/54)

A semiempirical method of estimating the forces on airfoils at near sonic speeds and in the presence of detached shock waves is presented. Fairly good agreement with the trend of existing experimental data is found at Mach numbers from 0.95 to 2.3 for sharp-nose airfoils at speeds and angles of attack above those at which shock detachment occurs and for blunt-nose airfoils where shock waves always are detached. Computed values of the forces on two-dimensional wings are in good agreement with wind-tunnel data on three-dimensional wings at high angles of attack. The approximate method is in agreement with Von Kármán transonic similarity laws.

NACA RM L9J12
National Advisory Committee for Aeronautics. LOW-SPEED STATIC LATERAL STABILITY CHARACTERISTICS OF A CANARD MODEL HAVING A 60° TRIANGULAR WING AND HORIZONTAL TAIL. William R. Bates. November 23, 1949. 29p. diagrs., tab. (NACA RM L9J12) (Declassified from Confidential, 8/18/54)

Contains results of force tests and flow surveys made in the Langley free-flight tunnel to determine the stability characteristics of a canard model having 60° triangular plan-form wing and horizontal tail. Tests were made with the horizontal tail used as a fixed nose elevator or floating freely at various tab deflections. Various vertical-tail configurations were also studied. Unusual directional stability characteristics were obtained from the results.

NACA RM L9J28

LOW-SPEED INVESTIGATION OF DEFLECTABLE WING-TIP AILERONS ON AN UNTAPERED 45° SWEPTBACK SEMISPAN WING WITH AND WITHOUT AN END PLATE. Jack Fischel and James M. Watson. December 14, 1949. 32p. diagrs., photo. (NACA RM L9J28) (Declassified from Confidential, 8/18/54)

Contains results and discussion of a low-speed investigation of triangular- and parallelogram-plan-form deflectable wing-tip ailerons on an untapered 45° sweptback semispan wing with and without a rectangular end plate (simulating a vertical fin) mounted on the wing inboard of the ailerons. Lift and lateral-control data were obtained through a large angle-of-attack range and a large aileron-deflection range for each aileron plan form on the plain wing and the wing with end plate. Aileron plan form had little or no effect, whereas the end plate had measurable effect on lift, drag, and rolling-moment data. These ailerons should provide adequate control over the entire angle-of-attack range.

NACA RM L9K10a

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 35°, ASPECT RATIO 6, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. William C. Sleeman, Jr. and William D. Morrison, Jr. December 12, 1949. 32p. diagrs., photos., tab. (NACA RM L9K10a) (Declassified from Confidential, 8/18/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a 35° sweptback wing with aspect ratio 6, taper ratio 0.6, and an NACA 65A006 airfoil section. Lift, drag, pitching moment, and root bending moment were obtained for the wing-alone and wing-fuselage configurations over a Mach number range of 0.60 to 1.18. Effective downwash angles and dynamic-pressure characteristics in the region of a probable tail location were also obtained and are presented for a range of tail heights at one tail length.

CURRENT NACA REPORTS

NACA Rept. 1135

EQUATIONS, TABLES, AND CHARTS FOR COMPRESSIBLE FLOW. Ames Research Staff. 1953. iii, 69p. diagrs., 25 charts, 2 tabs. (NACA Rept. 1135. Formerly TN 1428)

This report, which is a revision and extension of TN 1428, presents a compilation of equations, tables, and charts useful in the analysis of high-speed flow of a compressible fluid. The equations provide relations for continuous one-dimensional flow, normal and oblique shock waves, and Prandtl-Meyer expansions for both perfect and imperfect gases. The tables present useful dimensionless ratios for continuous one dimensional flow and for normal shock waves as functions of Mach number for air considered as a perfect gas. One series of charts presents the characteristics of the flow of air (considered a perfect gas) for oblique shock waves and for cones in a supersonic airstream. A second series shows the effects of caloric imperfections on continuous one-dimensional flow and on the flow through normal and oblique shock waves.

NACA Rept. 1153

ON THE APPLICATION OF TRANSONIC SIMILARITY RULES TO WINGS OF FINITE SPAN. John R. Spreiter. 1953. ii, 21p. diagrs. (NACA Rept. 1153. Formerly TN 2726)

The transonic aerodynamic characteristics of wings of finite span are discussed from the point of view of a unified small perturbation theory for subsonic, transonic, and supersonic flows about thin wings. This approach avoids certain ambiguities which appear if one studies transonic flows by means of equations derived under the more restrictive assumption that the local velocities are everywhere close to sonic velocity. The relation between the two methods of analysis of transonic flow is examined, the similarity rules and known solutions of transonic flow theory are reviewed, and the asymptotic behavior of the lift, drag, and pitching-moment characteristics of wings of large and small aspect ratio is discussed. It is shown that certain methods of data presentation are advantageous for the effective display of these characteristics.

NACA TM 1374

KINETIC TREATMENT OF THE NUCLEATION IN SUPERSATURATED VAPORS. (Kinetische Behandlung der Keimbildung in ubersattigten Dampfen). R. Becker and W. Döring. September 1954. 43p. diagrs. (NACA TM 1374. Trans. from Annalen der Physik, Ser. 5, v. 24, 1935, p. 719-752).

The equations of the individual processes of self nucleation are utilized through an electrical analogy to obtain the nucleation frequency. This process is shown to be shorter and less subject to error than that of previous investigators since the appearance of indeterminant integration constants is completely avoided. With the nucleation frequencies of crystals and spheres the Ostwald law of stages is reviewed and modified. In the final section the general resistance image is discussed and mention is made of the relation of the electrical network and Volmers formula.

NACA TN 3199

STRESS DISTRIBUTIONS CAUSED BY THREE TYPES OF LOADING ON A CIRCULAR SEMIMONOCOQUE CYLINDER WITH FLEXIBLE RINGS. Harvey G. McComb, Jr. September 1954. 54p. diagrs. (NACA TN 3199)

Equations are derived for the stress distributions caused by three types of loading on infinitely long, circular, semimonocoque cylinders with flexible rings. The results are given as formulas for the stringer loads and shear flows in the shell due to each type of loading. For each loading case these formulas can be used to construct tables of influence coefficients giving stringer loads and shear flows in the neighborhood of the load due to a unit magnitude of that load.

NACA TN 3231
National Advisory Committee for Aeronautics.
BENDING TESTS ON BOX BEAMS HAVING SOLID- AND OPEN-CONSTRUCTION WEBS. Aldie E. Johnson, Jr. August 1954. 25p. diagrs., photos., 2 tabs. (NACA TN 3231)

The results of an exploratory experimental investigation of the effects of replacing alternate webs in a multiweb beam by open, post-stringer construction are reported. Post-stringer (either upright or inclined posts) construction is shown to perform the function of comparable-weight, solid, fabricated webs in the stabilization of the compression cover of a beam in bending both before and after buckling.

NACA TN 3235
National Advisory Committee for Aeronautics.
LOW-SPEED YAWED-ROLLING AND SOME OTHER ELASTIC CHARACTERISTICS OF TWO 56-INCH-DIAMETER, 24-PLY-RATING AIRCRAFT TIRES. Walter B. Horne, Bertrand H. Stephenson and Robert F. Smiley. August 1954. 108p. diagrs., photos., 6 tabs. (NACA TN 3235)

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

The low-speed (up to 4 miles per hour) cornering characteristics of two 56 x 16, type VII, extra-high-pressure, 24-ply-rating tires were determined for a range of vertical loadings, yaw angles, and tire inflation pressures. Locked-wheel drag tests were also made for one vertical load condition. The quantities measured included cornering force, drag force, self-alining torque, pneumatic caster, vertical tire deflection, rolling radius, and relaxation length. Some supplementary tests were made which included measurements of tire footprint area, vertical-load-deflection characteristics, and the variation of tire radius and width with inflation pressure.

NACA TN 3303

TURBULENT-HEAT-TRANSFER MEASUREMENTS AT A MACH NUMBER OF 3.03. Maurice J. Brevoort and Bernard Rashis. September 1954. 21p. diagrs., tab. (NACA TN 3303)

A three-dimensional axially symmetric plug nozzle was used to obtain flat-plate data on turbulent-heat-transfer coefficients and recovery factors. The test results of this paper are for Mach number 3.03 and for a Reynolds number range of 5.6×10^6 to 6.5×10^7. The heat-transfer-coefficient results are in good agreement with theoretical analyses and the recovery-factor results are in good agreement with extrapolations of lower Reynolds number data.

MISCELLANEOUS

N-22929

Advisory Group for Aeronautical Research and Development. DIFFUSION FLAMES IN THE LABORATORY. John Barr. March 1954. 10p. diagrs. (Advisory Group for Aeronautical Research and Development. AG11/M7)

A survey of five recent reviews of diffusion flames is given. All the flames discussed are related to each other or can be obtained in a similar burner by varying the fuel type, the fuel and air flows or the static pressure. This survey tended to emphasize our lack of knowledge and the need for further research concerning the factors governing the structure, length and occurrence of diffusion flames.

UNPUBLISHED PAPERS

N-13524*

EXPERIMENTAL INVESTIGATION OF ICING PHENOMENA. (Experimentelle Untersuchung von Vereisungserscheinungen) Domenic Melcher. April 1954. 36p. diagrs., photos. (Trans. from Zeitschrift für angewandte Mathematik und Physik, v. 2, no. 6, 1951, p. 421-443)

An examination is made of the mechanism of icing phenomena. Artificial rime deposits of various types were produced and measurements made to establish the quantitative dependence of the deposit on temperature, H_2O-content, wind speed, and material of the body to be iced. The growth of the rime on metallic surfaces was observed under the polarizing microscope. An arrangement is described for studying rime in the open air, the purpose of which was to discover whether natural icing is a result of temperature effects. In addition, the influence of the electric field on the type of deposit was examined and measured.

NACA RM A6G24

THE SUBSONIC AERODYNAMIC CHARACTERISTICS OF TWO DOUBLE-WEDGE AIRFOIL SECTIONS SUITABLE FOR SUPERSONIC FLIGHT. Joseph Solomon and Floyd W. Henney. May 12, 1947. 33p. diagrs., photos. (NACA RM A6G24) (Declassified from Confidential, 8/18/54)

High-speed wind tunnel tests have been made to investigate the aerodynamic characteristics at subsonic speeds of two symmetrical double-wedge airfoil sections of 4- and 6-percent thickness. Section coefficients of lift, drag, and quarter-chord pitching moment are presented for a moderate range of angles of attack at Mach numbers up to approximately 0.93. Comparisons are made between the significant characteristics of the double-wedge airfoils and those of the NACA 65-206 airfoils as an index of the merit of the former at subsonic speeds.

NACA RM A7G15

AN EXPERIMENTAL INVESTIGATION AT SUPERSONIC SPEEDS OF ANNULAR DUCT INLETS SITUATED IN A REGION OF APPRECIABLE BOUNDARY LAYER. Wallace F. Davis, George B. Brajnikoff, David L. Goldstein and Joseph M. Spiegel. September 24, 1947. 41p. diagrs., photos. (NACA RM A7G15) (Declassified from Confidential, 8/18/54)

The recovery of total pressure after diffusion to a low subsonic velocity was found to be approximately two-thirds of that through a normal shock wave occurring at the same free-stream Mach number. The cause of this low-pressure recovery is the interaction between the boundary layer and the back pressure in the diffuser. Compression at a local Mach number comparable to that of the supersonic stream will result in large losses in total pressure if the compression occurs in the presence of an appreciable boundary layer.

NACA RM A8A13

PRESSURE RECOVERY AT SUPERSONIC SPEEDS THROUGH ANNULAR DUCT INLETS SITUATED IN A REGION OF APPRECIABLE BOUNDARY LAYER. I - ADDITION OF ENERGY TO THE BOUNDARY LAYER. Wallace F. Davis and George B. Brajnikoff. April 1, 1948. 22p. diagrs., photos. (NACA RM A8A13) (Declassified from Confidential, 8/18/54)

This report contains the results of an experimental investigation made at Mach numbers between 1.36 and 2.01 of the total-pressure recovery attainable with a model having a nozzle upstream of an annular duct inlet for the purpose of ejecting high-velocity air into the boundary layer of the flow along the forebody. A comparison of the total-pressure recovery effective in producing thrust is made between a hypothetical engine that recirculates air to the intake and one that does not. It was found that for the assumed conditions recirculation would increase the effective recovery about 8 percent.

NACA RM A8B16

AN EXPERIMENTAL INVESTIGATION OF NACA SUBMERGED INLETS AT HIGH SUBSONIC SPEEDS. I - INLETS FORWARD OF THE WING LEADING EDGE. Charles F. Hall and F. Dorn Barclay. June 9, 1948. 64p. diagrs., photos. (NACA RM A8B16) (Declassified from Confidential, 8/24/54)

Results are given of an experimental investigation of NACA submerged inlets with deflectors on a fighter airplane model at Mach numbers from 0.30 to 0.875. Data are presented showing the characteristics of the model without inlets and with inlets 16.7-percent wing-root chord forward of the wing leading edge. The results indicate that the ram recovery at the entrance was affected greatly by variations in mass-flow coefficient and only slightly by Mach number and angle-of-attack variations.

NACA RM A8C22

INVESTIGATION AT SUPERSONIC SPEED (M = 1.53) OF THE PRESSURE DISTRIBUTION OVER A 63° SWEPT AIRFOIL OF BICONVEX SECTION AT ZERO LIFT. Charles W. Frick and John W. Boyd. June 10, 1948. 33p. diagrs., photos. (NACA RM A8C22) (Declassified from Confidential, 8/18/54)

The results of an investigation at supersonic speed (M = 1.53) of the distribution of pressure at zero lift over the surface of a 63° swept airfoil of biconvex section (7 percent thick) are presented. The measured pressures are compared with theoretical values calculated from thin airfoil theory.

NACA RM A8F08

PRESSURE RECOVERY AT SUPERSONIC SPEEDS THROUGH ANNULAR DUCT INLETS SITUATED IN A REGION OF APPRECIABLE BOUNDARY LAYER. II - EFFECT OF AN OBLIQUE SHOCK WAVE IMMEDIATELY AHEAD OF THE INLET. George B. Brajnikoff. August 9, 1948. 15p. diagrs., photos. (NACA RM A8F08) (Declassified from Confidential, 8/18/54)

This report contains the results of an experimental investigation made at Mach numbers between 1.36 and 2.01 of the total-pressure recovery attainable with a model having a ramp ahead of an annular inlet for the purpose of reducing the entrance Mach number by means of an oblique shock wave. It was found that the recovery improved considerably with increasing ramp angle and that a model with a 15° ramp produced approximately four-fifths of the recovery through a normal shock wave occurring at the free-stream Mach number. Use of ramp angles greater than 15° resulted in unsteady flow through the induction system and a reduction in recovery.

NACA RM A8F21

AN EXPERIMENTAL INVESTIGATION AT LARGE SCALE OF SEVERAL CONFIGURATIONS OF AN NACA SUBMERGED AIR INTAKE. Norman J. Martin and Curt A. Holzhauser. October 19, 1948. 68p. diagrs., photos., 7 tabs. (NACA RM A8F21) (Declassified from Confidential, 8/18/54)

Results of an experimental investigation in the Ames 40- by 80-foot wind tunnel of NACA submerged inlets installed on a full-scale model of a fighter airplane are presented. Tests at various inlet-velocity ratios and angles of attack indicated the same favorable characteristics that had been noted at small scale. A small difference in the magnitude of pressure recovery measured at full scale and small scale was mainly accounted for by differences of boundary-layer thickness. The effect on pressure recovery of systematic changes of ramp divergence is also presented.

NACA RM A8F22

INVESTIGATION AT SUPERSONIC SPEED (M = 1.53) OF THE PRESSURE DISTRIBUTION OVER A 63° SWEPT AIRFOIL OF BICONVEX SECTION AT SEVERAL ANGLES OF ATTACK. John W. Boyd, Elliott D. Katzen and Charles W. Frick. September 24, 1948. 41p. diagrs., photos., tab. (NACA RM A8F22) (Declassified from Confidential, 8/18/54)

The results of an investigation at supersonic speed (M = 1.53) of the distribution of pressure at angles of attack over the surface of a 63° swept airfoil of biconvex section (7 percent thick) are presented. The measured pressures are compared with theoretical values calculated from supersonic lifting-surface theory.

NACA RM A8I16

AERODYNAMIC CHARACTERISTICS AT SUBSONIC AND SUPERSONIC MACH NUMBERS OF A THIN TRIANGULAR WING OF ASPECT RATIO 2. I - MAXIMUM THICKNESS AT 20 PERCENT OF THE CHORD. Robert E. Berggren and James L. Summers. November 19, 1948. 41p. diagrs., photos. (NACA RM A8I16) (Declassified from Confidential, 8/18/54)

This report presents the results of wind-tunnel tests to determine the variation with Mach number, from 0.50 to 1.49, of the lift, drag, and pitching-moment characteristics of a 5-percent-thick symmetrical double-wedge section triangular wing. The results are compared with results of tests of similar wings from other sources and with the characteristics calculated by current analytical methods.

NACA RM A8I20

AERODYNAMIC CHARACTERISTICS AT SUBSONIC AND SUPERSONIC MACH NUMBERS OF A THIN TRIANGULAR WING OF ASPECT RATIO 2. II - MAXIMUM THICKNESS AT MIDCHORD. Harold J. Walker and Robert E. Berggren. December 3, 1948. 41p. diagrs., photos. (NACA RM A8I20) (Declassified from Confidential, 8/18/54)

This report presents the results of wind-tunnel tests to determine the variation with Mach number between limits of 0.50 and 1.49 of the lift, drag, and pitching-moment characteristics of a 5-percent-thick triangular wing. The results are compared with the characteristics calculated by analytical methods. The effects upon the characteristics due to change in location of maximum profile thickness are also discussed.

NACA RM A8I29

RAM-RECOVERY CHARACTERISTICS OF NACA SUBMERGED INLETS AT HIGH SUBSONIC SPEEDS. Charles F. Hall and Joseph L. Frank. November 17, 1948. 44p. diagrs., photos. (NACA RM A8I29) (Declassified from Confidential, 8/18/54)

Results are presented of an experimental investigation of the characteristics of NACA submerged inlets on a model of a fighter airplane for Mach numbers from 0.30 to 0.875. The effects on the ram-recovery ratio at the inlets of Mach number, angle of attack, boundary-layer thickness on the fuselage, inlet location, and boundary-layer deflectors are shown. The data indicate only a slight decrease in ram-recovery ratio for the inlets ahead of or just behind the wing leading edge as Mach number increased, but showed large decreases at high Mach numbers for the inlets aft of the point of maximum thickness of the wing.

NACA RM A8L16

INVESTIGATION OF DOWNWASH AND WAKE CHARACTERISTICS AT A MACH NUMBER OF 1.53. I - RECTANGULAR WING. Edward W. Perkins and Thomas N. Canning. March 1, 1949. 29p. diagrs. (NACA RM A8L16) (Declassified from Confidential, 8/18/54)

The results of an experimental investigation of the downwash and wake characteristics behind a rectangular plan-form wing of aspect ratio 3.5 are presented. The airfoil section was a 5-percent-thick, symmetrical double wedge. The tests were made at a Mach number of 1.53 and a Reynolds number of 1.25 million. A comparison between experimental and theoretical values of the downwash angles is made.

NACA RM A9D20

INVESTIGATION OF DOWNWASH AND WAKE CHARACTERISTICS AT A MACH NUMBER OF 1.53. II - TRIANGULAR WING. Edward W. Perkins and Thomas N. Canning. June 6, 1949. 31p. diagrs. (NACA RM A9D20) (Declassified from Confidential, 8/18/54)

The results of an experimental investigation of the downwash and wake characteristics for a triangular plan-form wing of aspect ratio 2.04 are presented. The wing had a 5-percent-thick, symmetrical, double-wedge airfoil section. The tests were made at a Mach number of 1.53 and a Reynolds number of 2 million. A comparison between experimental and theoretical values of $(d\epsilon/d\alpha)_{\alpha=0}$ showed that the agreement was good within that part of the flow field where the theory predicts downwash for positive angles of attack of the wing. Within the remainder of the flow field the agreement was only fair. At finite angles of attack the measured downwash angles depart markedly from the values predicted by the theory.

NACA RM A9F16

A COMPARISON OF TWO SUBMERGED INLETS AT SUBSONIC AND TRANSONIC SPEEDS. Emmet A. Mossman. September 15, 1949. 31p. diagrs., photos. (NACA RM A9F16) (Declassified from Confidential, 8/18/54)

A qualitative experimental study of the effects of ramp-wall divergence on ram-pressure recovery has been made at Mach numbers up to 0.96. It is shown that the use of ramp-wall divergence considerably extends the Mach number range for satisfactory submerged-inlet operation. The increase in Mach number for satisfactory pressure recovery is attributed to a less severe interaction between the shock waves and the ramp boundary layer.

NACA RM A9F20

AN EXPERIMENTAL INVESTIGATION AT LARGE SCALE OF SINGLE AND TWIN NACA SUBMERGED SIDE INTAKES AT SEVERAL ANGLES OF SIDESLIP. Norman J. Martin and Curt A. Holzhauser. August 1, 1949. 31p. diagrs., photo. (NACA RM A9F20) (Declassified from Confidential, 8/18/54)

Results of an experimental investigation in the Ames 40- by 80-foot wind tunnel of single and twin NACA submerged-intake installations on a full-scale model of a fighter airplane at several angles of sideslip are presented. The effect of sideslip on the pressure-recovery and flow characteristics is shown. The effect of sideslip on pressure recovery and duct airflow instability was small.

NACA RM A9G15

THE EFFECT OF THE PROPELLER SLIPSTREAM ON THE CHARACTERISTICS OF SUBMERGED INLETS. Noel K. Delany. September 9, 1949. 41p. diagrs., photos. (NACA RM A9G15) (Declassified from Confidential, 8/18/54)

Wind-tunnel tests were made of submerged air inlets in the fuselage behind the propeller and forward of the wing of a 1/4-scale model of a hypothetical fighter airplane powered by a turbine-propeller unit. The results are presented for ramps with parallel and with divergent walls, and show the effect of propeller operation on the ram-recovery ratio at the entrance of the duct and at the simulated entrance of the compressor. The propeller used in these tests had dual rotation and had eight blades with thin shanks.

NACA RM A9H11

REDUCTION OF PROFILE DRAG AT SUPERSONIC VELOCITIES BY THE USE OF AIRFOIL SECTIONS HAVING A BLUNT TRAILING EDGE. Dean R. Chapman. November 1, 1949. 31p. diagrs., photo. (NACA RM A9H11) (Declassified from Confidential, 8/18/54)

A preliminary theoretical and experimental investigation has been made on the aerodynamic characteristics of blunt-trailing-edge airfoils at supersonic velocities. The theoretical considerations indicate that properly designed airfoils with moderately blunt trailing edges can have less profile drag, greater lift-curve slope, and a higher maximum lift-drag ratio than conventional sections. These predictions have been substantiated by experimental measurements on airfoils of 10-percent-thickness ratio at Mach numbers of 1.5 and 2.0, and at Reynolds numbers between 0.2 and 1.2 million.

NACA RM A9L01

WIND-TUNNEL INVESTIGATION AT MACH NUMBERS FROM 0.50 TO 1.20 OF AN ALL-MOVABLE TRIANGULAR WING OF ASPECT RATIO 4 ALONE AND WITH A BODY. Louis S. Stivers, Jr. and Alexander W. Malick. February 2, 1950. 45p. diagrs., photos., tab. (NACA RM A9L01) (Declassified from Confidential, 8/23/54)

Aerodynamic characteristics from wind-tunnel tests of semispan models are presented for an all-movable triangular wing alone and with a body (body attitude 0°). The wing had an aspect ratio of 4 and had doubly symmetrical double-wedge sections with maximum thickness-chord ratios of 0.08 in the streamwise direction. The tests were made at Mach numbers from 0.50 to about 0.98 and from 1.09 to 1.29. The corresponding Reynolds numbers varied from about 0.8×10^6 to 1.1×10^6. The experimental results are compared with calculated characteristics based on linear theory.

NACA RM A9L29

TESTS OF A SMALL-SCALE NACA SUBMERGED INLET AT TRANSONIC MACH NUMBERS. L. Stewart Rolls and George A. Rathert, Jr. February 23, 1950. 18p. diagrs., photos. (NACA RM A9L29) (Declassified from Confidential, 8/23/54)

The pressure-recovery characteristics of an NACA submerged inlet have been measured qualitatively in the Mach number range 0.60 to 1.08 by the wing-flow method. High ram-recovery ratios were maintained up to test-station Mach numbers of 1.03 to 1.08 where, for mass-flow ratios below 0.5, an abrupt loss in pressure recovery was measured.

NACA RM A50A04

STALL CHARACTERISTICS OBTAINED FROM FLIGHT 10 OF NORTHROP X-4 NO. 2 AIRPLANE (USAF NO. 46-677). Melvin Sadoff and Thomas R. Sisk. February 27, 1950. 25p. diagrs., photos., tab. (NACA RM A50A04) (Declassified from Confidential, 8/23/54)

Some limited results of stall characteristics have been obtained on a Northrop X-4 airplane. The results indicated that the motions of the airplane following the stall were mild and recovery was effected rapidly and completely with the use of down-elevon deflections. It was shown that the relative mildness of the stalls was probably due to the flat-top type of lift-curve characteristic of the 0010-64 airfoil section used, the plan form, and to the effect of sideslip on the stalling characteristics. It was further indicated that the low values of maximum normal-force coefficients obtained in gradual stall maneuvers could have been increased if corrective control had been used.

NACA RM A50C13

PRELIMINARY INVESTIGATION OF THE TRANSONIC CHARACTERISTICS OF AN NACA SUBMERGED INLET. John A. Axelson and Robert A. Taylor. June 5, 1950. 44p. diagrs., photos. (NACA RM A50C13) (Declassified from Confidential, 8/23/54)

Ram-recovery and pressure-distribution results for an NACA submerged inlet investigated on a transonic bump in the Ames 16-foot high-speed wind tunnel are presented for Mach numbers from 0.70 to 1.15, for simulated angles of attack of 0°, 4°, and 8°, and for mass-flow ratios between 0.25 and 0.68. The results indicate favorable ram-recovery characteristics for the inlet over the entire test range of Mach numbers, with the minimum ram recovery occurring around 1.05 Mach number.

NACA RM A50D27

LONGITUDINAL-STABILITY CHARACTERISTICS OF THE NORTHROP X-4 AIRPLANE (USAF NO. 46-677). Melvin Sadoff and Thomas R. Sisk. June 29, 1950. 24p. diagrs., photos., tab. (NACA RM A50D27) (Declassified from Confidential, 8/23/54)

The results obtained from several recent flights on the Northrop X-4 No. 2 airplane are presented. Information is included on the longitudinal-stability characteristics in straight flight over a Mach number range of 0.38 to about 0.63, the stability characteristics in accelerated flight over a Mach number range of 0.43 to 0.79, and the short-period longitudinal-oscillation characteristics at Mach numbers of 0.49 and 0.78. A description and a limited analysis of a pitch-up which was encountered during the accelerated stability tests at a Mach number of 0.79 and a normal-force coefficient of about 0.45 are also included.

NACA RM A50E26

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF METHODS OF ALLEVIATING THE ADVERSE INTERFERENCE AT THE ROOT OF A SWEPT-BACK WING. Lee E. Boddy. August 10, 1950. 31p. diagrs., photos. (NACA RM A50E26) (Declassified from Confidential, 8/23/54)

Tests were made of a model having the 50-percent-chord line of the wing unswept or swept back 35°. The tests with the swept-back wing included modifications to the body contour and to the wing section in the region of the wing-body juncture. The divergence Mach number of the swept-back wing agreed fairly well with that predicted from tests of the unswept wing using the simple cosine concepts. Either of the modifications increased the drag-divergence Mach number of the swept-back wing about 0.01.

NACA RM A50I01

SUMMARY REPORT OF RESULTS OBTAINED DURING DEMONSTRATION TESTS OF THE NORTHROP X-4 AIRPLANES. Melvin Sadoff and Thomas R. Sisk. December 13, 1950. 46p. diagrs., photos., tab. (NACA RM A50I01) (Declassified from Confidential, 8/23/54)

The results obtained during the demonstration flight tests of the Northrop X-4 No. 1 and No. 2 airplanes are presented. Information is included on the static and the dynamic longitudinal- and lateral-stability characteristics, the stalling characteristics, and the buffet boundary.

NACA RM A50I14a

INVESTIGATION OF THE DOWNWASH AND WAKE BEHIND A TRIANGULAR WING OF ASPECT RATIO 4 AT SUBSONIC AND SUPERSONIC MACH NUMBERS. Harold J. Walker and Louis S. Stivers, Jr. December 12, 1950. 32p. diagrs. (NACA RM A50I14a) (Declassified from Confidential, 8/23/54)

Downwash and wake characteristics for a thin, symmetrical, triangular wing are presented for angles of attack up to 10° and for Mach numbers from 0.50 to 1.29, corresponding to Reynolds numbers between 0.8×10^6 and 1.1×10^6. Downwash angles are shown for locations between the 25- and the 75-percent-semispan stations at a distance of about 0.8 root-chord length downstream from the trailing edge of the wing. The location and thickness of the wake are given for the 50-percent-semispan station at a distance of 3.44 root-chord lengths downstream from the trailing edge. A number of comparisons between the results from experiment and theory are also included.

NACA RM A50J09

LIFT AND MOMENT CHARACTERISTICS AT SUBSONIC MACH NUMBERS OF FOUR 10-PERCENT-THICK AIRFOIL SECTIONS OF VARYING TRAILING-EDGE THICKNESS. James L. Summers and William A. Page. December 20, 1950. 32p. diagrs., photos. (NACA RM A50J09) (Declassified from Confidential, 8/31/54)

The results of a wind-tunnel investigation from 0.3 to 0.9 Mach number of the lift and moment characteristics of four 10-percent-thick circular-arc airfoil sections having trailing-edge thicknesses of 0, 25, 50, and 100 percent of the maximum thickness are presented. It was observed that increases in the trailing-edge thickness resulted in increases in maximum lift coefficient and lift-curve slope at all Mach numbers and in increases in lift-divergence Mach number at all lift coefficients. Kármán vortex streets were produced by the thick trailing-edge sections indicating the presence of fluctuating lifts and high drags. It was further noted that a splitter plate at the trailing edge and in the chord plane eliminated the vortex streets.

NACA RM A50J09b

WIND-TUNNEL INVESTIGATION AT MACH NUMBERS FROM 0.50 TO 1.29 OF AN UNSWEPT TAPERED WING OF ASPECT RATIO 2.67 WITH LEADING- AND TRAILING-EDGE FLAPS - TRAILING-EDGE FLAPS DEFLECTED. Louis S. Stivers, Jr. and Alexander W. Malick. December 13, 1950. 45p. diagrs., photo., 5 tabs. (NACA RM A50J09b) (Declassified from Confidential, 8/31/54)

Aerodynamic characteristics are presented for an unswept wing having an aspect ratio of 2.67, a taper ratio of 0.5, and full-span, 25-percent-chord, plain, trailing-edge flaps. Sections of the wing were 8-percent chord thick from the 25- to the 75-percent-chord points tapering to sharp leading and trailing edges. The data were determined from wind-tunnel tests of the semispan model for a range of angles of attack from -3° to 12° and for a range of flap deflections from -10° to 60° at Mach numbers from 0.50 to about 0.98 and from 1.09 to 1.29. The corresponding Reynolds numbers varied from about 0.94×10^6 to 1.27×10^6.

NACA RM A50K10

WIND-TUNNEL INVESTIGATION AT MACH NUMBERS FROM 0.50 TO 1.29 OF AN UNSWEPT, TAPERED WING OF ASPECT RATIO 2.67 WITH LEADING- AND TRAILING-EDGE FLAPS - LEADING-EDGE FLAPS DEFLECTED. Louis S. Stivers, Jr. and Alexander W. Malick. February 26, 1951. 37p. diagrs., photo., 5 tabs. (NACA RM A50K10) (Declassified from Confidential, 8/31/54)

Results of a wind-tunnel investigation are presented for a semispan model of an unswept wing having an aspect ratio of 2.67, a taper ratio of 0.5, and full-span, 25-percent-chord, plain, leading-edge flaps. Sections of the wing in the streamwise direction were uniform 8-percent chord thick from the 25- to the 75-percent-chord points tapering to sharp leading and trailing edges. The data were obtained for a range of angles of attack from -3° to 12° and for a range of flap deflections from -20° to 10° at Mach numbers from about 0.50 to 0.95 and from 1.09 to 1.29. The corresponding Reynolds numbers varied from about 0.94×10^6 to about 1.27×10^6.

NACA RM A50K15

THE EFFECTS OF CENTRALLY MOUNTED WING-TIP TANKS ON THE SUBSONIC AERODYNAMIC CHARACTERISTICS OF A WING OF ASPECT RATIO 10 WITH 35° OF SWEEPBACK. Bruce E. Tinling and W. Richard Kolk. February 21, 1951. 44p. diagrs., photos., 2 tabs. (NACA RM A50K15) (Declassified from Confidential, 8/31/54)

This report presents results of a wind-tunnel investigation of the effects of centrally mounted wing-tip tanks on the aerodynamic characteristics of a wing having an aspect ratio of 10 with 35° of sweepback of the quarter-chord line. Three tip tanks of equal volume having fineness ratios of 10, 6.67, and 5 were tested. The effects of a vane near the tank-wing juncture were also investigated. Lift, drag, and pitching-moment data are presented. The Reynolds number of the tests was varied from 2,000,000 to 10,000,000 at a Mach number of 0.25, and the Mach number was varied from 0.25 to 0.90 at a Reynolds number of 2,000,000.

NACA RM A50K27

THE EFFECTS OF MACH NUMBER AND REYNOLDS NUMBER ON THE AERODYNAMIC CHARACTERISTICS OF SEVERAL 12-PERCENT-THICK WINGS HAVING 35° OF SWEEPBACK AND VARIOUS AMOUNTS OF CAMBER. Bruce E. Tinling and W. Richard Kolk. February 23, 1951. 68p. diagrs., photo., tab. (NACA RM A50K27) (Declassified from Confidential, 8/31/54)

Six semispan model wings with 35° of sweepback were tested: three of aspect ratio 10, and three of aspect ratio 5. The thickness distribution of the wing sections was the same from root to tip and there was no twist. The streamwise sections of the three wings of each aspect ratio were the NACA 65_1A012, the NACA 64_1A312, and the NACA 64_1A612. Lift, drag, and pitching-moment data are presented. The Reynolds number of the tests was varied from 2,000,000 to 10,000,000 at a Mach number of 0.25, and the Mach number was varied from 0.25 to 0.92 at a Reynolds number of 2,000,000.

NACA RM A50K27b

WIND-TUNNEL INVESTIGATION AT MACH NUMBERS FROM 0.50 TO 1.29 OF AN UNSWEPT, TAPERED WING OF ASPECT RATIO 2.67 WITH LEADING- AND TRAILING-EDGE FLAPS - FLAPS DEFLECTED IN COMBINATION. Louis S. Stivers, Jr. and Alexander W. Malick. February 26, 1951. 41p. diagrs., photo., 7 tabs. (NACA RM A50K27b) (Declassified from Confidential, 8/31/54)

Aerodynamic characteristics from wind-tunnel tests of a semispan model are presented for an unswept wing having an aspect ratio of 2.67, a taper ratio of 0.5, and full-span, 0.25 chord, plain, leading- and trailing-edge flaps. Sections of the wing were uniform 0.08 chord thick from the 0.25 to the 0.75 chord points and tapered to sharp leading and trailing edges. The data are presented for a range of angles of attack from -3° to 12° and for ranges of leading-edge-flap deflection from -20° to 10° and of trailing-edge-flap deflection from 0° to 60°. The Mach numbers ranged from about 0.50 to 0.98 and from 1.09 to 1.29 with corresponding Reynolds numbers varying from about 0.94×10^6 to 1.27×10^6.

NACA RM A50L12

PRELIMINARY INVESTIGATION OF THE DELAY OF TURBULENT FLOW SEPARATION BY MEANS OF WEDGE-SHAPED BODIES. George B. McCullough, Gerald E. Nitzberg and John A. Kelly. March 1, 1951. 28p. diagrs., photos. (NACA RM A50L12) (Declassified from Confidential, 8/31/54)

A wind-tunnel investigation of pyramidal, wedge-like bodies as devices for delaying separation of a turbulent boundary layer was conducted. The flow fields of individual wedges mounted on a flat plate and of multiple wedges applied to a two-dimensional airfoil were studied. Substantial increases of maximum lift and reductions of drag at high lift coefficients were realized at the expense of doubling the zero-lift drag. A brief investigation of vane-type vortex generators gave comparable increases of maximum lift with about one-half the incremental drag of the wedges at zero lift.

NACA RM A51A12

THE TRANSONIC CHARACTERISTICS OF 17 RECTANGULAR, SYMMETRICAL WING MODELS OF VARYING ASPECT RATIO AND THICKNESS. Warren H. Nelson and John B. McDevitt. May 10, 1951. 91p. diagrs., photos. (NACA RM A51A12) (Declassified from Confidential, 8/31/54)

An investigation utilizing the transonic-bump technique was made to determine the aerodynamic characteristics of transonic Mach numbers of 17 rectangular wings having aspect ratios of 6, 4, 2, and 1, and NACA 63A0XX sections with thickness-to-chord ratios of 10, 8, 6, 4, and 2 percent. The Mach number range was 0.4 to 1.1, corresponding under the test conditions to a Reynolds number range from 1.25 to 2.05 million. These data are presented without analysis.

NACA RM A51B16

EXPERIMENTAL DOWNWASH AND WAKE CHARACTERISTICS AT SUBSONIC AND SUPERSONIC MACH NUMBERS BEHIND AN UNSWEPT, TAPERED WING OF ASPECT RATIO 2.67 WITH LEADING- AND TRAILING-EDGE FLAPS. Harold J. Walker, Louis S. Stivers, Jr. and Luther Beard, Jr. April 20, 1951. 43p. diagrs. (NACA RM A51B16) (Declassified from Confidential, 8/31/54)

Results of a wind-tunnel investigation are presented which show the effects of flap deflection and Mach number on the downwash and wake characteristics at distances of 1.80 and 4.74 mean aerodynamic chord lengths, respectively, downstream from the midchord line of a semispan model of an unswept, tapered wing of aspect ratio 2.67 with full-span, 25-percent-chord, plain, leading- and trailing-edge flaps. Sections of the wing were 8-percent chord thick from the 25- to the 75-percent-chord points, and tapered to sharp leading and trailing edges. The data were obtained for flap deflections ranging from -20° to 40° at Mach numbers from 0.50 to 1.29. The corresponding Reynolds numbers varied from 0.94×10^{6} to 1.27×10^{6}.

NACA RM A51C14

A SEMIEMPIRICAL METHOD FOR CALCULATING THE PITCHING MOMENT OF BODIES OF REVOLUTION AT LOW MACH NUMBERS. Edward J. Hopkins. May 17, 1951. 27p. diagrs., tab. (NACA RM A51C14) (Declassified from Confidential, 8/31/54)

A semiempirical method, in which potential theory is arbitrarily combined with an approximate viscous theory, for calculating the aerodynamic pitching moments for bodies of revolution is presented. The method can also be used for calculating the lift and drag forces. The calculated and experimental force and moment characteristics of 15 bodies of revolution are compared.

NACA RM E7F13

INVESTIGATION OF SHOCK DIFFUSERS AT MACH NUMBER 1.85. III - MULTIPLE-SHOCK AND CURVED-CONTOUR PROJECTING CONES. W. E. Moeckel and J. F. Connors. August 13, 1947. 23p. diagrs., photos. (NACA RM E7F13) (Declassified from Confidential, 8/18/54)

The configurations tested were; a cone designed to produce three oblique shocks ahead of the diffuser inlet in combination with a straight and curved inlet section; a cone generated by a parabolic arc, also in combination with a curved and a straight inlet section; a cone-inlet combination designed by the method of characteristics to produce an isentropic entrance flow at an angle of attack of 0°; and a 30° single-shock cone in combination with a perforated inlet section. The effect of angle of attack was also investigated for the isentropic configuration.

NACA RM E7K21

COMPARISON OF HOVERING PERFORMANCE OF HELICOPTERS POWERED BY JET-PROPULSION AND RECIPROCATING ENGINES. Virginia L. Brightwell, Max D. Peters and J. C. Sanders. June 11, 1948. 39p. diagrs., 3 tabs. (NACA RM E7K21) (Declassified from Confidential, 8/18/54)

An analysis was made to compare the fuel consumptions of three jet engines and one reciprocating engine used to power helicopters in hovering flight at sea level. The calculations showed that the conventional reciprocating engine permitted much longer hovering time than the jet-propulsion engines investigated, but because the jet-propulsion engines were lighter than the reciprocating engine, the jet-propelled helicopters could lift greater disposable loads.

NACA RM E8C16

STUDY OF STRESS STATES IN GAS-TURBINE DISK AS DETERMINED FROM MEASURED OPERATING-TEMPERATURE DISTRIBUTIONS. J. Elmo Farmer, M. B. Millenson and S. S. Manson. July 21, 1948. 41p. diagrs., photos. (NACA RM E8C16) (Declassified from Confidential, 8/18/54)

Results are presented of an experimental investigation to determine the temperature distribution in an aircraft-engine gas-turbine disk. High axial- and radial-temperature gradients were found to exist both when the engine was accelerated as rapidly as possible to maximum speed and power output and when it was gradually brought to these conditions in a manner typical of normal service operation. Calculated stresses based on the measured temperature distributions are presented.

NACA RM E8K24

COMPARISON OF PERFORMANCE OF AN-F-58 AND AN-F-32 FUELS IN J33-A-23 TURBOJET ENGINE. H. D. Wilsted and J. C. Armstrong. June 2, 1949. 33p. photos., diagrs., tab. (NACA RM E8K24) (Declassified from Confidential, 8/18/54)

Performance of fuels corresponding to specifications AN-F-58 and AN-F-32 was investigated using a J33-A-23 turbojet engine. Comparatively, AN-F-58 fuel indicated equal performance in terms of engine thrust and fuel consumption, improved altitude starting, improved blow-out limits, higher but non-detrimental carbon-deposition rate, and iron oxide contamination. If contaminating iron oxide can be excluded from the engine, AN-F-58 fuel is considered satisfactory.

NACA RM E8K26

EXPERIMENTAL PRESSURE DISTRIBUTIONS OVER WING TIPS AT MACH NUMBER 1.9. I - WING TIP WITH SUBSONIC LEADING EDGE. James M. Jagger and Harold Mirels. January 27, 1949. 28p. diagrs., photo. (NACA RM E8K26) (Declassified from Confidential, 8/18/54)

An investigation was conducted at Mach number of 1.91 to determine spanwise pressure distribution over a wing tip in a region influenced by a sharp subsonic leading edge swept back at 70°. Except for pressure distribution on the top surface in the immediate vicinity of the subsonic leading edge, the maximum difference between linearized theory and experimental data was 2-1/2 percent (of free-stream dynamic pressure) for angles of attack up to 4° and 7 percent for angles of attack up to 8°. Pressures on the top surface nearest the subsonic edge indicated local expansions beyond values predicted by linearized theory.

NACA RM E8L24
National Advisory Committee for Aeronautics.
ALTITUDE PERFORMANCE OF AN-F-58 FUELS IN J33-A-21 SINGLE COMBUSTOR. Ralph T. Dittrich and Joseph L. Jackson. April 8, 1949. 23p. diagrs., 2 tabs. (NACA RM E8L24) (Declassified from Confidential, 8/18/54)

Three fuels conforming to AN-F-58 specification were investigated in order to determine the influence of boiling temperatures and aromatic content on altitude performance in single combustor of a 4600-pound-thrust turbojet engine. Combustion efficiencies of the three AN-F-58 fuels were approximately equal at each simulated engine condition for altitudes from 5,000 to 50,000 feet, 90-percent normal rated engine speed, and flight Mach numbers of 0.0 and 0.6.

NACA RM E9D06

CARBON DEPOSITION FROM AN-F-58 FUELS IN A J33 SINGLE COMBUSTOR. Jerrold D. Wear and Howard W. Douglass. June 24, 1949. 27p. diagrs., photos., 2 tabs. (NACA RM E9D06) (Declassified from Confidential, 8/18/54)

Effects of change in boiling temperature and aromatic content of AN-F-58 fuels on carbon deposition and change in simulated engine operating conditions on carbon deposition were evaluated in a J33 single combustor. Effect of carbon deposits in the combustor on altitude operational limits was investigated. Carbon deposition increased with increase in boiling temperature at constant aromatic content and with increase in aromatic content of the AN-F-58 fuels. Operational limits occurred at slightly lower altitudes when the combustor assembly contained carbon deposits than when it did not.

NACA RM E9H15

DOWNWASH IN VORTEX REGION BEHIND TRAPEZOIDAL-WING TIP AT MACH NUMBER 1.91. J. L. Cummings, H. Mirels and L. E. Baughman. November 10, 1949. 39p. diagrs., photos. (NACA RM E9H15) (Declassified from Confidential, 8/18/54)

Results of an experimental investigation to determine downwash and wake characteristics in region of trailing vortex system behind a trapezoidal-wing tip at Mach number 1.91 are presented. The wing was cut along inner Mach line from the tip and had a 5-percent-thick symmetrical diamond cross section. For small angles of attack, the experimental spanwise variation of $-d\epsilon/d\alpha$ (where ϵ is the downwash angle and α is the angle of attack) was generally similar to the variation predicted by linearized theory. At higher angles of attack, differences between the experimental and theoretical variations were attributed to a modification of the spanwise distribution of shed vorticity and a distortion of the shed vortex sheet.

NACA RM E9H17

ANALYTICAL DETERMINATION OF EFFECT OF WATER INJECTION ON POWER OUTPUT OF TURBINE-PROPELLER ENGINE. Albert O. Ross and Merle C. Huppert. November 3, 1949. 29p. diagrs. (NACA RM E9H17) (Declassified from Confidential, 8/18/54)

An analysis is presented to show the effect of evaporative cooling of the charge air during compression on the performance of a turbine-propeller engine incorporating a centrifugal compressor. Calculations were made with water as the cooling agent for compressor tip speeds of 1200, 1500, and 1800 feet per second. Results indicated that a power augmentation of 200 percent is possible at a compressor tip speed of 1800 feet per second if sufficient water is evaporated during compression to saturate the air at the compressor outlet.

NACA RM E9I22a

EXPERIMENTAL PRESSURE DISTRIBUTIONS OVER WING TIPS AT MACH NUMBER 1.9. II - WING TIP WITH SUBSONIC TRAILING EDGE. Harold Mirels and James M. Jagger. December 21, 1949. 23p. diagrs., photo. (NACA RM E9I22a) (Declassified from Confidential, 8/18/54)

An investigation was conducted at Mach number 1.90 to determine experimental pressure distribution over a wing tip in region influenced by sharp subsonic trailing edge. Experimental pressure distribution in region influenced by subsonic trailing edge was generally in poor agreement with linearized theory. Difference between theory and experiment was attributed to separation associated with adverse pressure gradient predicted by linearized theory for this region.

NACA RM E50D05

EXPERIMENTAL INVESTIGATION OF SUPERSONIC FLOW WITH DETACHED SHOCK WAVES FOR MACH NUMBERS BETWEEN 1.8 AND 2.9. W. E. Moeckel. July 5, 1950. 56p. diagrs., photos., 4 tabs. (NACA RM E50D05) (Declassified from Confidential, 8/23/54)

An experimental investigation of the flow near the nose of plane and axially symmetric bodies was conducted to check the predictions of theory. The location of the detached wave was determined for a variety of nose forms over a range of Mach numbers from 1.8 to 2.9. At a Mach number of 1.9, the form of the detached wave and the pressure distribution near the nose were also investigated. In addition, the relation between shock location and flow spillage was determined for several nose inlets. Most of the experimental results agreed to good approximation with the results predicted by the one-dimensional continuity method.

NACA RM E50D19

EFFECT OF INLET TEMPERATURE AND HUMIDITY ON THRUST AUGMENTATION OF TURBOJET ENGINE BY COMPRESSOR-INLET INJECTION. Thomas B. Shillito and James L. Harp, Jr. July 3, 1950. 46p. diagrs., photos. (NACA RM E50D19) (Declassified from Confidential, 8/23/54)

An investigation was conducted to determine the effect of inlet temperature and humidity on turbojet-engine performance with water-alcohol injection at the compressor inlet. At a constant total liquid flow (fuel flow plus injected flow) the augmented thrust ratio increased with compressor-inlet temperature. At a given inlet temperature and injection rate, the thrust decreased slightly with increasing humidity.

NACA RM E50E03a

EXPERIMENTAL INVESTIGATION OF SPREADING CHARACTERISTICS OF CHOKED JETS EXPANDING INTO QUIESCENT AIR. Morris D. Rousso and Fred D. Kochendorfer. August 9, 1950. 39p. diagrs., photos., tab. (NACA RM E50E03a. Now RM E51F18) (Declassified from Confidential, 8/23/54)

The boundaries of single and twin jets discharging into quiescent air are presented for several values of nozzle-outlet pressure ratio and spacing between nozzles. The effects of jet temperature, Reynolds number, and humidity on jet spreading are briefly evaluated. The results indicate that for a jet temperature ratio of 2.6 the pressure boundaries are slightly smaller than those of corresponding unheated jets and that the effects of Reynolds number and humidity are negligible.

NACA RM E50F12

INVESTIGATION OF PERFORATED CONVERGENT-DIVERGENT DIFFUSERS WITH INITIAL BOUNDARY LAYER. Maynard I. Weinstein. August 15, 1950. 26p. diagrs., photo. (NACA RM E50F12) (Declassified from Confidential, 8/23/54)

An experimental investigation was made at Mach number 1.90 of the performance of a series of perforated convergent-divergent supersonic diffusers operating with initial boundary layer, which was induced and controlled by lengths of cylindrical inlets affixed to the diffusers. Supercritical mass-flow and peak total-pressure recoveries were decreased slightly by use of the longest inlets (4 inlet diameters in length). Combinations of cylindrical inlets, perforated diffusers, and a subsonic diffuser were evaluated as simulated wind tunnels having second throats. Comparisons with noncontracted configurations of similar scale indicated conservatively computed power reductions of 25 percent.

NACA RM E50H10

DOWNWASH IN VORTEX REGION BEHIND RECTANGULAR HALF-WING AT MACH NUMBER 1.91. John L. Cummings and Rudolph C. Haefeli. October 26, 1950. 43p. diagrs., photos., tab. (NACA RM E50H10) (Declassified from Confidential, 8/23/54)

Results of an experimental investigation to determine downwash and wake characteristics in region of trailing vortex system behind a rectangular half-wing at Mach number 1.91 are presented. The wing had a 5-percent thick symmetric diamond cross section beveled to a knife edge at the tip. At small angles of attack, downwash angles were in close agreement with predictions of linearized theory based on the assumption of an undistorted vortex sheet. At higher angles of attack, the flow was greatly influenced by the rolling up of the vortex sheet.

NACA RM E50H28

COMBUSTION EFFICIENCY AND ALTITUDE OPERATIONAL LIMITS OF THREE LIQUID HYDROCARBON FUELS HAVING HIGH VOLUMETRIC ENERGY CONTENT IN A J33 SINGLE COMBUSTOR. Edward G. Stricker. November 6, 1950. 22p. diagrs., tab. (NACA RM E50H28) (Declassified from Confidential, 8/23/54)

Combustion efficiency and altitude operational limits were determined in a J33 single combustor for AN-F-58 fuel and three liquid hydrocarbon fuels having high volumetric energy content (decalin, tetralin, and monomethylnaphthalene) at simulated altitude and combustor inlet-air conditions. At the conditions investigated, the combustion efficiency for the four fuels generally decreased with an increase in volumetric energy content. The altitude operational limits for decalin and tetralin fuels were higher than for AN-F-58 fuel; monomethylnaphtalene fuel gave the lowest altitude operational limit.

NACA RM E50H29

INVESTIGATION OF POWER REQUIREMENTS FOR ICE PREVENTION AND CYCLICAL DE-ICING OF INLET GUIDE VANES WITH INTERNAL ELECTRIC HEATERS. Uwe von Glahn and Robert E. Blatz. December 1, 1950. 49p. diagrs., photos. (NACA RM E50H29) (Declassified from Confidential, 8/23/54)

An investigation was conducted to determine the electric power requirements for turbojet-engine inlet guide vanes with continuous heating and with cyclical de-icing for a range of icing conditions. Minimum total power requirements for continuous heating and dyclical de-icing are presented in terms of average surface datum temperature. An analysis is included to extend the experimentally obtained continuous heating data to vane sizes and icing conditions other than those investigated. Cyclical de-icing provides a total power saving as high as 79 percent over continuous heating for a typical engine installation. Heat-on periods of 10 seconds or less with heat-off periods of 60 seconds are recommended for cyclical de-icing.

NACA RM E50I08

ICING CHARACTERISTICS AND ANTI-ICING HEAT REQUIREMENTS FOR HOLLOW AND INTERNALLY MODIFIED GAS-HEATED INLET GUIDE VANES. Vernon H. Gray and Dean T. Bowden. December 5, 1950. 49p. diagrs., photos. (NACA RM E50I08) (Declassified from Confidential, 8/23/54)

Gas temperatures and flow rates required for anti-icing a two-dimensional cascade of turbojet inlet guide vanes were determined for hollow and internally modified vanes. The pressure losses caused by icing on unheated guide vanes were also determined. Less heat was required for anti-icing internally modified blades than for the hollow blades. Pressure losses across the cascade were greater at an inlet temperature of 22° F than at 0° F because of the characteristic shapes of ice deposits at the two temperatures.

NACA RM E50K14

SUPERSONIC TUNNEL INVESTIGATION BY MEANS OF INCLINED-PLATE TECHNIQUE TO DETERMINE PERFORMANCE OF SEVERAL NOSE INLETS OVER MACH NUMBER RANGE OF 1.72 TO 2.18. Jerome L. Fox. February 14, 1951. 27p. diagrs., photos. (NACA RM E50K14) (Declassified from Confidential, 8/31/54)

A suspended flat plate was used to continuously vary the Mach number in the NACA Lewis 18- by 18-inch Mach number 1.91 supersonic tunnel. Useful range of the tunnel was extended over range of Mach numbers from 1.72 to 2.18. Maximum variations in Mach number of the flow produced at vicinity of nose inlets at zero angle of attack were ±0.01 and flow angularities were less than approximately 0.35°. The technique was applied to determination of pressure recovery and mass-flow characteristics of four supersonic nose inlets over Mach number range produced.

NACA RM E50L08

INVESTIGATION OF THREE TYPES OF SUPERSONIC DIFFUSER OVER A RANGE OF MACH NUMBERS FROM 1.75 TO 2.74. L. Eugene Baughman and Lawrence I. Gould. March 12, 1951. 37p. diagrs., photos. (NACA RM E50L08) (Declassified from Confidential, 8/31/54)

An investigation was conducted to determine the off-design pressure recovery, mass-flow, and thrust characteristics of a normal-shock diffuser, two single-shock spike diffusers, and three convergent-divergent perforated diffusers operating in the Mach number range between 1.75 and 2.74.

NACA RM L6I11

DRAG MEASUREMENTS OF A 34° SWEPT-FORWARD AND SWEPT-BACK NACA 65-009 AIRFOIL OF ASPECT RATIO 2.7 AS DETERMINED BY FLIGHT TESTS AT SUPERSONIC SPEEDS. Sidney R. Alexander. February 20, 1947. 11p. diagrs., photos. (NACA RM L6I11) (Declassified from Confidential, 8/18/54)

The data were obtained by tracking rocket-propelled winged bodies moving at supersonic speeds. The test results show that for the comparable Mach number range investigated (M = 0.9 - 1.30) both the 34° swept-forward and swept-back airfoils produced lower values of zero-lift drag than the unswept airfoil. At Mach numbers between 1.0 and 1.3, the drag of the swept-back wing was about 50 percent and that of the swept-forward wing about 65 percent of the unswept wing.

NACA RM L6K21

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A SEMISPAN AIRPLANE MODEL WITH A SWEPT-BACK TAIL FROM TESTS AT TRANSONIC SPEEDS BY THE NACA WING-FLOW METHOD. John A. Zalovcik and Richard H. Sawyer. March 28, 1947. 30p. diagrs., photos., tab. (NACA RM L6K21) (Declassified from Confidential, 8/18/54)

The model was mounted in such a way as to permit it to assume a position of zero pitching moment about the center of gravity at 27 percent of the mean aerodynamic chord. Measurements were made of lift and angle of attack for trim for several stabilizer and elevator settings. Because of the chordwise variation of Mach number in the test region, the effective Mach number for the wing of the model was lower than that for the tail of the model.

NACA RM L6L09

OBSERVATIONS ON AN AILERON-FLUTTER INSTABILITY ENCOUNTERED ON A 45° SWEPT-BACK WING IN TRANSONIC AND SUPERSONIC FLIGHT. Marvin Pitkin, William N. Gardner and Howard J. Curfman, Jr. April 11, 1947. 23p. diagrs., photos. (NACA RM L6L09) (Declassified from Confidential, 8/18/54)

Flight data are presented showing the free-floating and oscillatory characteristics of the wing and aileron. It is shown that aileron vibration occurred at flight velocities corresponding to a Mach number range from 1.03 to 1.4. The frequencies of the aileron and wing oscillations were identical at a given Mach number, were of the order of 100 cycles per second, and increased with Mach number. The test data indicate that aileron compressibility flutter is delayed in appearance but not prevented by sweepback.

NACA RM L6L24

DRAG OF A WING-BODY CONFIGURATION CONSISTING OF A SWEPT-FORWARD TAPERED WING MOUNTED ON A BODY OF FINENESS RATIO 12 MEASURED DURING FREE FALL AT TRANSONIC SPEEDS. Jim Rogers Thompson and Charles W. Mathews. March 13, 1947. 15p. diagrs., photos. (NACA RM L6L24) (Declassified from Confidential, 8/18/54)

The total drag and the drag of the wing were measured separately. These measurements were made to determine optimum aerodynamic shapes and configurations for use in the transonic and supersonic velocity ranges, and show that the drag of the complete configuration rose almost linearly from 0.07 of atmospheric pressure per unit of frontal area at a Mach number of 0.90 to 0.30 of atmospheric pressure at a Mach number of 1.02.

NACA RM L6L30

DRAG MEASUREMENTS OF A SWEPT-BACK WING HAVING INVERSE TAPER AS DETERMINED BY FLIGHT TESTS AT SUPERSONIC SPEEDS. Sidney R. Alexander. April 8, 1947. 12p. diagrs., photo. (NACA RM L6L30) (Declassified from Confidential, 8/18/54)

The test results showed that for the comparable Mach number range investigated (M = 1.0 to 1.275), the tapered wing produced values of drag coefficient that averaged about 30 percent lower than those of the 34° swept-back untapered wing and about 20 percent higher than those of the 45° swept-back untapered wing. At Mach numbers of 1.1 and 1.2, the tapered wing revealed drag coefficients of 0.0195 and 0.0225, the latter value being the maximum value obtained for this arrangement. The data were obtained by radar tracking of the rocket-propelled winged body moving at supersonic speeds.

NACA RM L7A03

FORCE AND LONGITUDINAL CONTROL CHARACTERISTICS OF A 1/16 – SCALE MODEL OF THE BELL XS-1 TRANSONIC RESEARCH AIRPLANE AT HIGH MACH NUMBERS. Axel T. Mattson. May 21, 1947. 32p. diagrs., photo., tab. (NACA RM L7A03) (Declassified from Confidential, 8/18/54)

The results given do not present completely the force and longitudinal control characteristics of the model. General trends are illustrated, however, which can be qualitatively analyzed for level-flight Mach numbers up to 0.93. A large increase in drag coefficient occurs beyond a Mach number of 0.78. At a Mach number of approximately 0.825 an initial lift force break occurs. This force break, up to a Mach number of approximately 0.875, is not severe, although elevator-control effectiveness is decreasing. At a Mach number of 0.9, use of the stabilizer as a trim control is required.

NACA RM L7E08

MEASUREMENTS OF THE EFFECTS OF THICKNESS RATIO AND ASPECT RATIO ON THE DRAG OF RECTANGULAR-PLAN-FORM AIRFOILS AT TRANSONIC SPEEDS. Jim Rogers Thompson and Charles W. Mathews. June 20, 1947. 17p. diagrs., photo. (NACA RM L7E08) (Declassified from Confidential, 8/18/54)

In the present paper results are presented for two airfoils of the series (those having NACA 65-012 sections and aspect ratios of 7.6 and 5.1) and are compared with results for other airfoils of the series which were previously reported. At sonic and low supersonic speeds the pressure-drag coefficient was found to vary in proportion to the square of the thickness ratio between values of thickness ratio of 0.09 and 0.12 but between values of thickness ratio of 0.06 and 0.09 the exponent was somewhat less than 2.

NACA RM L7E26

FLIGHT TESTS TO DETERMINE THE EFFECT OF TAPER ON THE ZERO-LIFT DRAG OF WINGS AT LOW SUPERSONIC SPEEDS. Sidney R. Alexander and Robert L. Nelson. July 13, 1947. 19p. diagrs., photos. (NACA RM L7E26) (Declassified from Confidential, 8/18/54)

At a constant leading-edge sweep of 45° no orderly variation of drag coefficient with taper ratio occurs, the variation being dependent upon the Mach number. Maximum thickness, leading-edge, and trailing-edge sweep are all important in determining the drag coefficient of a tapered wing. A comparison is made between the results of theoretical drag calculations of tapered wings and applicable experimental values derived herein.

NACA RM L7G02

A TORSIONAL STIFFNESS CRITERION FOR PREVENTING FLUTTER OF WINGS OF SUPERSONIC MISSILES. Bernard Budiansky, Joseph N. Kotanchik and Patrick T. Chiarito. August 28, 1947. 14p. diagrs., tab. (NACA RM L7G02) (Declassified from Confidential, 8/18/54)

Failures probably due to flutter were encountered in NACA flight tests of several rocket-powered, drag-research missiles that were intended to attain Mach numbers of about 1.4. The wing failures of these missiles led to the development of a simple, semi-rational torsional stiffness criterion for preventing flutter of uniform, sweptback or unswept missile wings that attain supersonic speeds. Results of missile flights at speeds up to Mach number 1.4 demonstrate the usefulness of the formula.

NACA RM L7K20

WIND-TUNNEL INVESTIGATION OF A WING-FUSELAGE COMBINATION WITH EXTERNAL STORES. H. Norman Silvers and Kenneth P. Spreemann. July 9, 1948. 55p. diagrs. (NACA RM L7K20) (Declassified from Confidential, 8/18/54)

Contains drag measurements of several external-store installations specifically designed to delay the advent of airplane buffet due to stores which has been recognized in wing-tunnel data as a sharp increase of the drag coefficient of the external-store installation. Results indicate that of the arrangements tested the highest store drag rise Mach number may be obtained by locating the store maximum thickness at large chordwise distance from the wing maximum thickness or by attaching the store flush to the wing lower surface, thus eliminating the pylon suspension system typical of current installations.

NACA RM L8A28a

FACTORS AFFECTING LATERAL STABILITY AND CONTROLLABILITY. John P. Campbell and Thomas A. Toll. May 13, 1948. 19p. diagrs. (NACA RM L8A28a) (Declassified from Confidential, 8/18/54)

The effects on dynamic lateral stability and controllability of some of the important aerodynamic and mass characteristics are discussed and methods are presented for estimating the various stability parameters to be used in the calculation of the dynamic lateral stability of airplanes with swept and low-aspect-ratio wings.

NACA RM L8H31

AN INVESTIGATION OF THE LOW-SPEED STATIC STABILITY CHARACTERISTICS OF COMPLETE MODELS HAVING SWEPTBACK AND SWEPT FORWARD WINGS. M. Leroy Spearman and Paul Comisarow. November 19, 1948. 51p. diagrs., tab. photos. (NACA RM L8H31) (Declassified from Confidential, 8/18/54)

An investigation has been conducted in the Langley 300 mph 7- by 10-foot tunnel to determine the static stability characteristics at low speeds of complete models with various swept wings so that comparisons might be made with available theoretical and emphirical methods of predicting the stability characteristics. Longitudinal and lateral stability characteristics, flaps up and down, were obtained for models having 0°, 15°, 30°, and 45° sweptforward and sweptback wings.

NACA RM L8J28

SUMMARY OF RESULTS OF TUMBLING INVESTIGATIONS MADE IN THE LANGLEY 20-FOOT FREE-SPINNING TUNNEL ON 14 DYNAMIC MODELS. Ralph W. Stone, Jr. and Robert L. Bryant. December 31, 1948. 91p. diagrs., photos., 23 tabs. (NACA RM L8J28) (Declassified from Confidential, 8/18/54)

The tumbling characteristics of dynamic models of 14 specific airplane designs tested in the Langley 20-foot free-spinning tunnel for various loadings and configurations have been summarized. Both tailless and conventional airplane configurations were considered. Sweep angles varied from 15° forward to a 60° delta wing. Aspect ratios varied from 1.27 to 10.6. Consideration has also been given to the problem of accelerations encountered during a tumble, pilot escape, and use of wing-tip parachutes for termination of the tumbling motion.

NACA RM L9A17

PRELIMINARY TANK INVESTIGATION OF THE USE OF SINGLE MONOPLANE HYDROFOILS FOR HIGH-SPEED AIRPLANES. Douglas A. King and John A. Rockett. March 22, 1949. 35p. diagrs., photos., 6 tabs. (NACA RM L9A17) (Declassified from Confidential, 8/18/54)

Presents results of hydrodynamic take-off and landing tests of a model of a hypothetical high-speed airplane fitted with a variety of single hydrofoils mounted near the center of gravity. Instability occurred during take-off when the hydrofoil of any configuration emerged. The hydrodynamic resistance was greater than that of conventional hulls.

NACA RM L9A21

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 45°, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Joseph Weil and Kenneth W. Goodson. February 24, 1949. 28p. diagrs., photo., tab. (NACA RM L9A21) (Declassified from Confidential, 8/18/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a wing with the quarter-chord line swept back 45°, with aspect ratio 4, taper ratio 0.6, and an NACA 65A006 airfoil section. Lift, drag, pitching moment, and root bending moment were obtained for the isolated wing and wing-body configurations in a Mach number range between 0.6 and 1.18. Effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were also obtained and are presented for a range of tail heights at one tail length. The effects of two wing-fence arrangements were also investigated.

NACA RM L9A31

STABILITY AND CONTROL DATA OBTAINED FROM FIRST FLIGHT OF X-4 AIRPLANE. Hubert M. Drake. February 7, 1949. 11p. diagrs., photos., tab. (NACA RM L9A31) (Declassified from Confidential, 8/18/54)

Results are presented from the first flight of NACA instrumented Northrop X-4 semitailless research airplane. Data presented include rudder and elevon position, and angle of sideslip for various airspeeds up to 290 miles per hour indicated and 11,000 feet pressure altitude. The airplane exhibited a slight degree of static longitudinal instability for certain conditions.

NACA RM L9B02

FULL-SCALE INVESTIGATION OF A WING WITH THE LEADING EDGE SWEPT BACK 47.5° AND HAVING CIRCULAR-ARC AND FINITE-TRAILING-EDGE-THICKNESS AILERONS. Roy H. Lange. March 11, 1949. 16p. diagrs., photo. (NACA RM L9B02) (Declassified from Confidential, 8/18/54)

The results of an investigation in the Langley full-scale tunnel to determine the aerodynamic characteristics of a wing with the leading edge swept back 47.5° and having a 20-percent-chord, 50-percent-span outboard-flap-type aileron are presented in this paper. The wing had circular-arc airfoil sections, and the aileron was investigated for the circular-arc contour and for a flat-sided contour with finite trailing-edge thickness. The aileron effectiveness was determined and the data are presented for a Reynolds number of 4.3×10^6 and a Mach number of about 0.07.

NACA RM L9B08

SOME WIND-TUNNEL EXPERIMENTS ON SINGLE DEGREE OF FREEDOM FLUTTER OF AILERONS IN THE HIGH SUBSONIC SPEED RANGE. Sherman A. Clevenson. March 30, 1949. 33p. diagrs., photo., 3 tabs. (NACA RM L9B08) (Declassified from Confidential, 8/18/54)

Results of tests of three wing models with various aileron configurations are presented. Density had little effect on the initial magnitude or initial Mach number of buzz. Buzz frequency decreased with decrease of density. Initial buzz Mach number decreases with increasing angle of attack. Mass balancing and changes of spring stiffness of the ailerons in these tests had little effect on buzz. Increasing the aileron mass moment of inertia lowers the buzz frequency. Placing the aileron at the wing tip delays the onset of buzz. A comparison of the test results with two empirical analyses is made.

NACA RM L9B10a

THE EFFECT OF REAR CHINE STRIPS ON THE TAKE-OFF CHARACTERISTICS OF A HIGH-SPEED AIRPLANE FITTED WITH NACA HYDRO-SKIS. John A. Ramsen. March 17, 1949. 7p. diagrs., photo. (NACA RM L9B10a) (Declassified from Confidential, 8/18/54)

Results are presented from tank take-off tests of a dynamic model of a hypothetical high-speed airplane fitted with NACA hydro-skis and having the transverse curvature of the lower rear portion of the fuselage broken by small longitudinal chine strips. For the configuration tested, both trim and resistance were considerably reduced by the addition of the strips from the speed at which the ski emerged to the speed at which the rear of the fuselage came clear of the water. Results indicate that fuselage shape has a large effect on the take-off characteristics for a hydro-ski configuration in which the rear of the fuselage acts as a planing surface.

NACA RM L9B23a

MEASUREMENTS OF AERODYNAMIC CHARACTERISTICS OF A 35° SWEPTBACK NACA 65-009 AIRFOIL MODEL WITH 1/4-CHORD HORN-BALANCED FLAP BY THE NACA WING-FLOW METHOD. Harold I. Johnson and B. Porter Brown. April 18, 1949. 59p. diagrs., photo. (NACA RM L9B23a) (Declassified from Confidential, 8/18/54)

Contains lift, pitching-moment, and hinge-moment data obtained from wing-flow tests of a low-aspect-ratio sweptback airfoil model having a full-span 1/4-chord horn-balanced flap. Mach number range was 0.55 to 1.15. Data are compared with results obtained from previous tests of an equivalent plain-flap model. Conclusion is that horn balance appears satisfactory for $M < 0.95$ but will not be useful between $M \approx 0.95$ and $M = 1.15$.

NACA RM L9B25

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 35°, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. William C. Sleeman, Jr. and Robert E. Becht. April 21, 1949. 29p. diagrs., photo., tab. (NACA RM L9B25) (Declassified from Confidential, 8/18/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a wing with quarter-chord line swept back 35°, aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil section. Lift, drag, pitching moment, and root bending moment were obtained for the wing-alone and wing-body configurations over a Mach number range of 0.6 to 1.18. Effective downwash angles and dynamic-pressure characteristics in the region of a probable tail location were also obtained and are presented for a range of tail heights at one tail length.

NACA RM L9C01

APPARATUS FOR OBTAINING A SUPERSONIC FLOW OF VERY SHORT DURATION AND SOME DRAG MEASUREMENTS OBTAINED WITH ITS USE. John E. Yeates, Jr., F. J. Bailey, Jr. and T. J. Voglewede. July 23, 1951. 23p. diagrs., photos. (NACA RM L9C01) (Declassified from Confidential, 8/18/54)

Contains description of a vacuum-actuated supersonic nozzle and a comparison of drag data obtained from free-fall tests and models tested using this equipment. The comparison indicates that the apparatus gives drag values in good agreement with free-fall, free-flight, and wind-tunnel tests and it should also give good results for comparative drag studies for which this equipment was primarily designed.

NACA RM L9C11

STUDY BY NACA WING-FLOW METHOD OF TRANSONIC DRAG CHARACTERISTICS OF A BLUNT-NOSE BODY OF REVOLUTION AND COMPARISON WITH RESULTS FOR A SHARP-NOSE BODY. J. Ford Johnston and Mitchell Lopatoff. April 26, 1949. 26p. diagrs., photos. (NACA RM L9C11) (Declassified from Confidential, 8/18/54)

Contains studies by NACA wing-flow method of pressure distributions and pressure drag of a body of revolution with NACA 1-50-100 nose inlet at zero inlet flow at Mach numbers from 0.70 to 1.10. Comparison is made with pressure-drag characteristics of a sharp-nose body having same rear end. Consideration of component front- and rear-end drag contributions suggests general picture of body-drag variation in transonic speed range.

NACA RM L9C18

PRESSURE-DISTRIBUTION DATA FOR THE NACA 64_1-012 AND 64_1A012 AIRFOILS AT HIGH SUBSONIC MACH NUMBERS. Milton D. Humphreys. May 6, 1949. 37p. photos., diagrs., 8 tabs. (NACA RM L9C18) (Declassified from Confidential, 8/18/54)

Pressure-distribution tests and schlieren photographs of the NACA 64_1012 and 64_1A012 airfoils indicated that the primary effect of increasing the trailing-edge angle from 9° to 14° was to decrease the loading over the rear portion of the airfoil. The effect was more pronounced with increasing Mach numbers and lift coefficients.

NACA RM L9C25

ERROR IN AIRSPEED MEASUREMENT DUE TO STATIC-PRESSURE FIELD AHEAD OF SHARP-NOSE BODIES OF REVOLUTION AT TRANSONIC SPEEDS. Edward C. B. Danforth and J. Ford Johnston. August 19, 1949. 31p. diagrs., photos. (NACA RM L9C25) (Declassified from Confidential, 8/18/54)

Contains measurements of static-pressure error at several distances ahead of two sharp-nose bodies of revolution at zero angle of attack in the transonic speed range by the NACA wing-flow method. By application of the linearized subsonic theory and the transonic similarity rule to the data contained herein, the position error at any reasonable distance ahead of any sharp-nose body of revolution with an approximately parabolic nose profile and fineness ratio greater than about 4.5 can be predicted at any Mach number.

NACA RM L9D01

PRELIMINARY WIND-TUNNEL INVESTIGATION AT HIGH-SUBSONIC SPEEDS OF PLANING-TAIL, BLENDED, AND AIRFOIL-FOREBODY SWEPT HULLS. John M. Riebe and Richard G. MacLeod. September 12, 1949. 33p. diagrs., photos., 3 tabs. (NACA RM L9D01) (Declassified from Confidential, 8/23/54)

A preliminary investigation was made in the Langley high-speed 7- by 10-foot tunnel to determine the high subsonic aerodynamic characteristics of three different types of flying-boat hull: namely, a planing-tail hull, a blended hull, and an airfoil-forebody swept hull. For comparative purposes a body of revolution representative of the fuselage of a modern high-speed airplane was also included. The hull and fuselage data presented include the forces and moments of a 51.3° sweptback wing; the models were tested as reflection-plane half-models on the side wall of the tunnel. The results include the lift, drag, and pitching-moment coefficients through angles of attack from -1° to 4° up to Mach numbers to 0.99.

NACA RM L9D06

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE LATERAL-CONTROL CHARACTERISTICS OF AN AILERON AND A STEPPED SPOILER ON A WING WITH LEADING EDGE SWEPT BACK 51.3°. Leslie E. Schneiter and John R. Hagerman. June 7, 1949. 34p. diagrs., photo. (NACA RM L9D06) (Declassified from Confidential, 8/18/54)

Contains results and discussion of an investigation to a Mach number of about 0.9 of the lateral-control characteristics of a 20-percent-chord by 39-percent-semispan plain sealed aileron and a 60-percent-span stepped spoiler on a semispan-wing model of aspect ratio 3.0 and leading edge swept back 51.3°. The general wing aerodynamic characteristics were also determined in this investigation.

NACA RM L9D06a

MEASUREMENT OF THE DYNAMIC LATERAL STABILITY OF THE DOUGLAS D-558-1 AIRPLANE (BUAERO NO. 37971) IN RUDDER KICKS AT A MACH NUMBER OF 0.72. Hubert M. Drake. May 31, 1949. 10p. diagrs., photos. (NACA RM L9D06a) (Declassified from Confidential, 8/18/54)

Contains results of flight measurements of the dynamic lateral stability of the Douglas D-558-1 airplane at a Mach number of 0.72 and a pressure altitude of 8500 feet.

NACA RM L9D07

INVESTIGATIONS AT SUPERSONIC SPEEDS OF 22 TRIANGULAR WINGS REPRESENTING TWO AIRFOIL SECTIONS FOR EACH OF 11 APEX ANGLES. Eugene S. Love. May 10, 1949. 100p. diagrs., photos., 3 tabs. (NACA RM L9D07) (Declassified from Confidential, 8/18/54)

The results of tests of 22 triangular wings, representing two leading-edge shapes for each of 11 apex angles, at Mach numbers of 1.62, 1.92, and 2.40 are presented and compared with theory. All wings have a common thickness ratio of 8 percent and a common location of maximum thickness point of 18 percent. Lift, drag, and pitching moment are given for all wings at each Mach number. The relation of transition in the boundary layer, shocks on the wing surfaces, and characteristics of the pressure distributions is discussed for several wings.

NACA RM L9D11

FLIGHT INVESTIGATION OF THE JETTISONABLE-NOSE METHOD OF PILOT ESCAPE USING ROCKET-PROPELLED MODELS. Reginald R. Lundstrom and Burke R. O'Kelly. June 2, 1949. 27p. diagrs., photos., 2 tabs. (NACA RM L9D11) (Declassified from Confidential, 8/18/54)

Results of an investigation at a Mach number of 0.87 of the jettisonable-nose method of pilot escape, using rocket-propelled models, is presented. With a fin-stablized nose section the accelerations produced are well within human tolerance. The drag-weight ratios of nose and rear bodies were such that the deceleration of the nose was less than that of the rear body. The shielding effect of the nose on the rear body was appreciable, and forcible separation appears necessary.

NACA RM L9D13

MEASUREMENTS OF AILERON EFFECTIVENESS OF BELL X-1 AIRPLANE UP TO A MACH NUMBER OF 0.82. Hubert M. Drake. June 20, 1949. 7p. diagrs. (NACA RM L9D13) (Declassified from Confidential, 8/18/54)

Contains results of flight measurements of the aileron effectiveness of the Bell X-1 airplane up to a Mach number of 0.82. The data indicate that Mach number has little effect on the aileron effectiveness up to a Mach number of 0.82.

NACA RM L9D20

THE EFFECT OF AIR-JET AND STRIP MODIFICATIONS ON THE HYDRODYNAMIC CHARACTERISTICS OF THE STREAMLINE FUSELAGE OF A TRANSONIC AIRPLANE. Bernard Weinflash, Kenneth W. Christopher and Charles L. Shuford, Jr. June 3, 1949. 32p. diagrs., photos. (NACA RM L9D20) (Declassified from Confidential, 8/18/54)

Specific free-to-trim tests were made on a 1/12-size model of a streamline fuselage modified by patterns of air jets or strips on the fuselage bottom. The effects of spacing of jets, length of jet rows, and direction of jets were determined for a simulated chine configuration. Tests were also made of a

simulated multiple-step configuration. The effect of air flow on both the chine and step configurations was studied. In addition, the effect of substituting narrow breaker strips for the rows of jets in the chine configuration and in three multiple-step configurations was investigated. Data are presented on resistance, trim, effective hydrodynamic lift, and spray.

NACA RM L9D20a

MEASURED CHARACTERISTICS OF THE DOUGLAS D-558-1 AIRPLANE (BUAERO NO. 37971) IN TWO LANDINGS. Hubert M. Drake. June 3, 1949. 8p. diagrs., photos. (NACA RM L9D20a) (Declassified from Confidential, 8/18/54)

Records were obtained of two landings which indicate approach and landing speeds of 150 and 115 percent of the estimated minimum speed. The rates of descent just prior to the start of the landing flare were about 1200 to 1800 feet per minute.

NACA RM L9E10

EFFECTS OF MACH NUMBER AND SWEEP ON THE DAMPING-IN-ROLL CHARACTERISTICS OF WINGS OF ASPECT RATIO 4. Richard E. Kuhn and Boyd C. Myers, II. June 27, 1949. 28p. diagrs., photo. (NACA RM L9E10) (Declassified from Confidential, 8/18/54)

The damping-in-roll characteristics of three wings of aspect ratio 4 and taper ratio 0.6 with sweep angles of 3.6°, 32.6°, and 46.7° at the quarter-chord line and the NACA 65A006 section have been determined through the Mach number range from 0.4 to 0.91 and angle-of-attack range from 0° to 6.5° in the Langley high-speed 7- by 10-foot tunnel by the free-roll method. Rolling-moment and rate-of-roll data for each wing are presented for an angle-of-attack range from 0° to 6.5° and aileron angles of 0°, ±4°, and ±8°. Aileron effectiveness and the damping-in-roll parameter C_{l_p} are presented for these conditions along with a comparison with theory.

NACA RM L9E19

AERODYNAMIC CHARACTERISTICS OF SEVERAL 6-PERCENT-THICK AIRFOILS AT ANGLES OF ATTACK FROM 0° TO 20° AT HIGH SUBSONIC SPEEDS. Bernard N. Daley and Douglas R. Lord. July 14, 1949. 63p. diagrs., photos. (NACA RM L9E19) (Declassified from Confidential, 8/18/54)

Gives aerodynamic characteristics obtained from experimental two-dimensional tests of eight 6-percent-thick symmetrical airfoils of the supersonic and subsonic type at angles of attack from 0° to 20° and at Mach numbers from 0.3 to about 0.9. Results indicate generally improved characteristics for the circular-arc and wedge-type airfoils when the maximum thickness was located forward. The variations with Mach number of the lift, drag, and pitching-moment coefficients are generally similar for the supersonic- and subsonic-type airfoils tested.

NACA RM L9E25

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 45°, ASPECT RATIO 4, TAPER RATIO 0.3, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Boyd C. Myers, II and Thomas J. King, Jr. July 20, 1949. 28p. diagrs., photo., tab. (NACA RM L9E25) (Declassified from Confidential, 8/18/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a wing with quarter-chord line swept back 45° with aspect ratio 4, taper ratio 0.3, and NACA 65A006 airfoil. Lift, drag, pitching moment, and root bending moment were obtained for the isolated wing and wing-fuselage configurations over a Mach number range 0.70 to 1.18. Effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were also obtained and are presented for a range of tail heights at one tail length. In order to expedite publishing of these data only a brief analysis has been made.

NACA RM L9F14

EFFECT OF SWEEPBACK ON THE LOW-SPEED STATIC AND ROLLING STABILITY DERIVATIVES OF THIN TAPERED WINGS OF ASPECT RATIO 4. William Letko and Walter D. Wolhart. August 9, 1949. 36p. diagrs., photo. (NACA RM L9F14) (Declassified from Confidential, 8/18/54)

Contains results of an investigation made in the rolling-flow test section of the Langley stability tunnel to determine the effects of sweepback on the static and rolling derivatives of a series of wings each of which had a taper ratio of 0.6 and an aspect ratio of 4. The wings were of NACA 65A006 section and had sweepback angles of their quarter-chord line of 3.6°, 32.6°, and 46.7°. Most of the results are for wings tested in combination with a fuselage. The damping-in-roll results are compared with those obtained from free rotation of the models in the Langley 7- by 10-foot tunnel, and some comparisons are made with theory.

NACA RM L9F15

DAMPING-IN-ROLL CHARACTERISTICS OF A 42.7° SWEPT-BACK WING AS DETERMINED FROM A WIND-TUNNEL INVESTIGATION OF A TWISTED SEMISPAN WING. Vernard E. Lockwood. August 8, 1949. 23p. diagrs. (NACA RM L9F15) (Declassified from Confidential, 8/18/54)

This paper presents the results of a damping-in-roll investigation of a sweptback wing as determined from tunnel tests of a twisted semispan wing. The wing of the investigation had a leading-edge sweep of 42.7°, a taper ratio of 0.5, an aspect ratio of 4.0, and a circular-arc airfoil section normal to the 50-percent chord line. The tests were made in the transonic speed range between Mach numbers 0.6 and 1.15 in the Langley high-speed 7- by 10-foot tunnel by utilizing the transonic bump and at a Mach number of 1.9 in the Langley 9- by 12-inch supersonic blowdown tunnel.

NACA RM L9F21

RESULTS OBTAINED FROM SECOND FLIGHT OF X-4 AIRPLANE (A.F. NO. 46-676). Walter C. Williams. July 18, 1949. 13p. diagrs., photos., tab. (NACA RM L9F21) (Declassified from Confidential, 8/18/54)

Results are presented from the second flight of the NACA instrumented Northrop X-4 semitailless research airplane. Data presented include static-longitudinal-stability measurements and a time history of a landing approach and landing with the center of gravity at 19.7 percent mean aerodynamic chord. The airplane exhibited positive static longitudinal stability and low damping of the lateral oscillation.

NACA RM L9F28a

AN NACA VANE-TYPE ANGLE-OF-ATTACK INDICATOR FOR USE AT SUBSONIC AND SUPERSONIC SPEEDS. Jesse L. Mitchell and Robert F. Peck. August 16, 1949. 10p. diagrs., photos. (NACA RM L9F28a) (Declassified from Confidential, 8/18/54)

A description is presented of a vane-type angle-of-attack indicator developed by the NACA for use at supersonic and subsonic speeds. A brief history of the development and a wind-tunnel calibration are given, together with a discussion of the corrections to be applied to the indicated readings.

NACA RM L9F29

TESTS OF LIFTING SURFACES ON CONICAL AND CYLINDRICAL PORTIONS OF A BODY AT SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. Robert S. Osborne and John B. Wright. September 2, 1949. 22p. diagrs. (NACA RM L9F29) (Declassified from Confidential, 8/18/54)

Tests have been conducted at a Mach number of 1.2 and at several subsonic speeds to determine the possibilities of using a subsonic conical-flow field in a supersonic free stream to delay the onset of adverse compressibility effects on lifting surfaces.

NACA RM L9F29a

LATERAL-CONTROL INVESTIGATION OF FLAP-TYPE CONTROLS ON A WING WITH QUARTER-CHORD LINE SWEPT BACK 45°, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Raymond D. Vogler. August 15, 1949. 22p. diagrs. (NACA RM L9F29a) (Declassified from Confidential, 8/18/54)

This paper presents the results of a lateral-control investigation of a 30-percent-chord flap-type control of various spanwise magnitudes on a wing of 45° of sweepback of the quarter-chord line, an aspect ratio of 4, a taper ratio of 0.6, and an NACA 65A006 airfoil section. Rolling and pitching moments and lift of the semispan wing fuselage were obtained through a Mach number range of 0.6 to 1.20.

NACA RM L9G06a

INVESTIGATION OF THE NACA 4-(5)(08)-03 TWO-BLADE PROPELLER AT FORWARD MACH NUMBERS TO 0.925. James B. Delano and Melvin M. Carmel. September 15, 1949. 61p. diagrs., photo. (NACA RM L9G06a) (Declassified from Confidential, 8/23/54)

The paper presents propeller characteristics for the NACA 4-(5)(08)-03 two-blade propeller for forward Mach numbers up to 0.925 for blade angles from 20° to 70°.

NACA RM L9G20a

RESULTS OBTAINED FROM THIRD FLIGHT OF NORTHROP X-4 AIRPLANE (A.F. NO. 46-676). Walter C. Williams. September 9, 1949. 13p. diagrs., photos., tab. (NACA RM L9G20a) (Declassified from Confidential, 8/18/54)

Results are presented from the third flight of the NACA instrumented Northrop X-4 semitailless research airplane. Data presented are steady sideslip characteristics at 175 miles per hour which show that directional stability is positive and high and lateral stability is positive.

NACA RM L9G22

THE STATIC-PRESSURE ERROR OF WING AND FUSELAGE AIRSPEED INSTALLATIONS OF THE X-1 AIRPLANES IN TRANSONIC FLIGHT. Harold R. Goodman and Roxanah B. Yancey. July 22, 1949. 20p. diagrs. (NACA RM L9G22) (Declassified from Confidential, 8/18/54)

Contains measurements of the static-pressure error of the airspeed installations of the X-1 airplanes obtained from flight tests made in the Mach number range of 0.8 to 1.32. The static-pressure error was measured at a point ahead of the fuselage nose and at a point ahead of the wing tip. Data are presented showing the variation of the static-pressure error with Mach number, airplane lift coefficient, and wing thickness.

NACA RM L9G22a

AERODYNAMIC CHARACTERISTICS OF A DELTA WING WITH LEADING EDGE SWEPT BACK 45°, ASPECT RATIO 4, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. William C. Sleeman, Jr. and Robert E. Becht. September 6, 1949. 29p. diagrs., photo., tab. (NACA RM L9G22a) (Declassified from Confidential, 8/18/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a delta wing with leading edge swept back 45°, aspect ratio 4, and an NACA 65A006 airfoil section. Lift, drag, pitching moment, and root bending moment were obtained for the wing-alone and wing-fuselage configurations over a Mach number range of 0.60 to 1.18. Effective downwash angles and dynamic-pressure characteristics in the region of a probable tail location were also obtained and are presented for a range of tail heights at one tail length.

NACA RM L9G25a

STABILITY AND CONTROL DATA OBTAINED FROM FOURTH AND FIFTH FLIGHTS OF THE NORTHROP X-4 AIRPLANE (A.F. NO. 46-676). George M. Valentine. August 4, 1949. 22p. diagrs., photos., tab. (NACA RM L9G25a) (Declassified from Confidential, 8/18/54)

Results are presented from the fourth and fifth flights of the NACA instrumented Northrop X-4 semitailless research airplane. Data presented from steady level runs from 140 to 340 miles per hour which showed the airplane to be longitudinally stable, stick fixed, in the clean configuration and in the gear-down flaps-retracted configuration. Data also are presented from steady sideslip characteristics at 175 to 280 miles per hour which show that the directional stability is positive and high and lateral stability is positive.

NACA RM L9G27

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 60°, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Thomas J. King, Jr. and Boyd C. Myers, II. September 6, 1949. 32p. diagrs., photos., tab. (NACA RM L9G27) (Declassified from Confidential, 8/18/54)

The paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a wing with quarter-chord line swept back 60° with aspect ratio 4, taper ratio 0.6, and 65A006 airfoil. Lift, drag, pitching-moment, and root-bending moment characteristics were obtained for the isolated-wing and wing-fuselage configurations over a Mach number range from 0.60 to 1.18. In addition, the effect of a fence, mounted at the mean aerodynamic chord, is also discussed. Effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were also obtained and are presented for a range of tail heights at one tail length. In order to expedite publishing of these data only a brief analysis has been made.

NACA RM L9H04

INVESTIGATION OF EXTENSIBLE WING-TIP AILERONS ON AN UNTAPERED SEMISPAN WING AT 0° AND 45° SWEEPBACK. John R. Hagerman and William M. O'Hare. September 20, 1949. 40p. diagrs.; photo., tab. (NACA RM L9H04) (Declassified from Confidential, 8/18/54)

Contains results and discussion of a low-speed lateral control investigation of three different plan forms of extensible wing-tip ailerons on each of two untapered wing configurations, one unswept with aspect ratio of 3.13 and the other swept back 45° with aspect ratio of 1.59. The results indicate that the extensible ailerons had satisfactory rolling effectiveness at moderate and high values of lift coefficient but insufficent rolling effectiveness at low values of lift coefficient for satisfactory application to an airplane. However, these ailerons may be suitable for use on some types of missiles. The extensible ailerons produced yawing moments comparable to those produced by conventional flap-type ailerons.

NACA RM L9H16

WIND-TUNNEL INVESTIGATION AT LOW TRANSONIC SPEEDS OF THE EFFECTS OF NUMBER OF WINGS ON THE LATERAL-CONTROL EFFECTIVENESS OF AN RM-5 TEST VEHICLE. Harold S. Johnson. November 29, 1949. 15p. diagrs., photo., tab. (NACA RM L9H16) (Declassified from Confidential, 8/18/54)

Contains results of a wind-tunnel investigation conducted to determine the effects of number of wings on the rolling characteristics of an RM-5 test vehicle through a speed range to a Mach number of 0.9.

NACA RM L9H22

AERODYNAMIC CHARACTERISTICS OF A WING WITH UNSWEPT QUARTER-CHORD LINE, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Kenneth W. Goodson and William D. Morrison, Jr. October 21, 1949. 32p. diagrs., photos., tab. (NACA RM L9H22) (Declassified from Confidential, 8/18/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a wing with unswept quarter-chord line, aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil section. Lift, drag, pitching moment, and root bending moment were obtained for the wing-alone and wing-body configurations over a Mach number range of 0.6 to 1.18. Effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were also obtained and are presented for a range of tail heights at one tail length.

NACA RM L9H29a

INVESTIGATION OF SOME TURBULENT-BOUNDARY-LAYER VELOCITY PROFILES AT A TUNNEL WALL WITH MACH NUMBERS UP TO 1.2. Marshall P. Tulin and Ray H. Wright. November 9, 1949. 22p. diagrs. (NACA RM L9H29a) (Declassified from Confidential, 8/18/54)

Turbulent-boundary-layer profiles at large Reynolds numbers, of the order of 40,000 based on the momentum thickness, and at Mach numbers up to 1.2 are presented and analyzed. The effects of compressibility on the profiles and on the displacement and momentum thicknesses are discussed. The turbulent boundary layer under a normal shock is investigated.

NACA RM L9I01

A FREE-FLIGHT TECHNIQUE FOR MEASURING DAMPING IN ROLL BY USE OF ROCKET-POWERED MODELS AND SOME INITIAL RESULTS FOR RECTANGULAR WINGS. James L. Edmondson and E. Claude Sanders, Jr. December 20, 1949. 25p. diagrs., photos. (NACA RM L9I01) (Declassified from Confidential, 8/18/54)

A simplified method for obtaining damping in roll experimentally at transonic and supersonic speeds through use of a simple rocket-powered model employing canted nozzles to apply a torque has been developed. A description of the method and results of the initial flight tests of rectangular wings with aspect ratio 3.71 are presented.

NACA RM L9I06

INVESTIGATION OF THE NACA 4-(3)(08)-03 TWO-BLADE PROPELLER AT FORWARD MACH NUMBERS TO 0.925. James B. Delano and Francis G. Morgan, Jr. November 2, 1949. 30p. diagrs., photos. (NACA RM L9I06) (Declassified from Confidential, 8/23/54)

Propeller characteristics are presented for the NACA 4-(3)(08)-03 blade propeller for forward Mach numbers up to 0.925 for blade angles of 55°, 60°, and 65°. A comparison of results for this propeller with those for the NACA 4-(5)(08)-03 propeller is presented to show the effect of design camber on propeller performance.

NACA RM L9I06a

STATIC STABILITY OF FUSELAGE HAVING A RELATIVELY FLAT CROSS SECTION. William R. Bates. December 9, 1949. 29p. diagrs., tab. (NACA RM L9I06a) (Declassified from Confidential, 8/18/54)

Contains results of force tests and flow surveys made in the Langley free-flight tunnel to determine the static stability characteristics of several fuselages having a relatively flat cross section and a high fineness ratio.

NACA RM L9I07

INVESTIGATION OF THE NACA 4-(4)(06)-04 TWO-BLADE PROPELLER AT FORWARD MACH NUMBERS TO 0.925. James B. Delano and Daniel E. Harrison. October 28, 1949. 39p. diagrs., photos. (NACA RM L9I07) (Declassified from Confidential, 8/23/54)

The paper presents propeller characteristics for the NACA 4-(4)(06)-04 two-blade propeller for forward Mach numbers up to 0.925 for blade angles from 20° to 70°.

NACA RM L9I08

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 45°, ASPECT RATIO 6, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Kenneth W. Goodson and Albert G. Few, Jr. November 1, 1949. 34p. diagrs., photos., tab. (NACA RM L9I08) (Declassified from Confidential, 8/18/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-alone and a wing-fuselage combination employing a wing with quarter-chord line swept back 45°, aspect ratio 6, taper ratio 0.6, and NACA 65A006 airfoil section. Lift, drag, pitching moment, and root bending moment were obtained for the wing-alone and wing-fuselage configurations over a Mach number range from 0.60 to 1.18. Effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were also obtained and are presented for a range of tail heights at one tail length.

NACA RM L9I28

AN EMPIRICAL CRITERION FOR FIN STABILIZING JETTISONABLE NOSE SECTIONS OF AIRPLANES. Stanley H. Scher. December 8, 1949. 21p. diagrs., photo., tab. (NACA RM L9I28) (Declassified from Confidential, 8/18/54)

The present paper summarizes the results of investigations in the Langley 20-foot free-spinning tunnel which show the inherent instability of models of jettisonable nose sections. A criterion is presented from which, for a given center-of-gravity position, the fin area required for stabilization of airplane nose sections can be determined.

NACA RM L9J04

EFFECT OF AIRFOIL SECTION AND TIP TANKS ON THE AERODYNAMIC CHARACTERISTICS AT HIGH SUBSONIC SPEEDS OF AN UNSWEPT WING OF ASPECT RATIO 5.16 AND TAPER RATIO 0.61. H. Norman Silvers and Kenneth P. Spreemann. December 1, 1949. 30p. diagrs., photos., 2 tabs. (NACA RM L9J04) (Declassified from Confidential, 8/18/54)

An investigation of a wing of aspect ratio 5.16 and of taper ratio 0.61 with two airfoil sections and a tip tank was made in the Langley high-speed 7- by 10-foot tunnel over a Mach number range that generally extended from 0.60 to 0.90. In addition to the effect of airfoil section and tip tank on the lift, drag, and pitching-moment coefficients of the wing alone and the wing-tank combination, tests included the effect of two modifications to the trailing edge of one section and horizontal stabilizing fins on the tip tank. Pitching moment and lift of the tank alone in the presence of the wing with one airfoil section were also measured.

NACA RM L9J05

INVESTIGATION AT MACH NUMBER 1.62 OF THE PRESSURE DISTRIBUTION OVER A RECTANGULAR WING WITH SYMMETRICAL CIRCULAR-ARC SECTION AND 30-PERCENT-CHORD TRAILING-EDGE FLAP. K. R. Czarnecki and James N. Mueller. January 25, 1950. 81p. diagrs., photos. (NACA RM L9J05) (Declassified from Confidential, 8/23/54)

Contains the results of an investigation at a Mach number of 1.62 and a Reynolds number range of 0.55 to 1.07×10^6 of the pressure distributions over a rectangular wing having a 9-percent-thick circular-arc section and a 30-percent-chord trailing-edge flap. The characteristics of the air flow at two spanwise stations, one in the two-dimensional flow region and the other in the region influenced by the airfoil tip, are discussed.

NACA RM L9J13

WIND-TUNNEL INVESTIGATION AT LOW SPEED TO DETERMINE AERODYNAMIC PROPERTIES OF A JETTISONABLE NOSE SECTION WITH CIRCULAR CROSS SECTION. Roscoe H. Goodwin. May 19, 1950. 38p. diagrs., photos. (NACA RM L9J13) (Declassified from Confidential, 8/23/54)

The aerodynamic properties of a model of a jettisonable nose section with a circular cross section were determined at low speed from an investigation in the Langley 20-foot free-spinning tunnel. Force and moment measurements were made of the nose section in various positions removed from the fuselage and in a position simulating its final condition of free fall (not under the influence of the fuselage). For each location of the nose, the measurements were obtained for the nose with and without stabilizing fins attached for 0° and 5° angle of attack.

NACA RM L9J13a

THE PATH AND MOTION OF SCALE MODELS OF JETTISONABLE NOSE SECTIONS AT SUPERSONIC SPEEDS AS DETERMINED FROM AN INVESTIGATION IN THE LANGLEY FREE-FLIGHT APPARATUS. Lawrence J. Gale. May 23, 1950. 35p. diagrs., photos., 2 tabs. (NACA RM L9J13a) (Declassified from Confidential, 8/23/54)

An investigation has been conducted on models of two different designs of jettisonable nose sections wherein the nose sections have been projected at supersonic speeds (Mach number ranged from 1.2 to 1.4) in the Langley free-flight apparatus. Both nose designs in the original unstabilized condition turned away from a nose-first flight attitude and calculations indicated that a pilot within corresponding full-scale nose sections would encounter large accelerations (12 negative g for 0.014 sec for one nose design and 26 negative g for 0.013 sec for the other design) as a result of this instability. Both nose designs with fins installed appeared stable, and calculations indicated that the equivalent motion in a corresponding full-scale nose section would not subject the pilot to large accelerations (6 transverse g).

NACA RM L9J19

THE EFFECT OF TIP TANKS ON THE ROLLING CHARACTERISTICS AT HIGH SUBSONIC MACH NUMBERS OF A WING HAVING AN ASPECT RATIO OF 3 WITH QUARTER-CHORD LINE SWEPT BACK 35°. Richard E. Kuhn and Boyd C. Myers, II. January 17, 1950. 27p. diagrs., photo., 2 tabs. (NACA RM L9J19) (Declassified from Confidential, 8/23/54)

An investigation of the effect of two wing-tip mounted tank configurations on the rolling characteristics of a swept wing through the Mach number range from 0.4 to 0.91 and in the angle-of-attack range from 0.3° to 6.5° was conducted by the free-roll method. An additional tank configuration was tested through the Mach number range at a constant angle of attack of 0.3°. Tanks mounted directly on the tip increased both the aileron effectiveness and the damping in roll. Pylon-mounted tanks gave a much smaller increase in both of these quantities. The variation of damping in roll with Mach number was similar and slightly greater than the wing alone for all configurations tested at a constant angle of attack of 0.3°.

NACA RM L9J27

MEASUREMENTS OF THE DRAG AND PRESSURE DISTRIBUTION ON A BODY OF REVOLUTION THROUGHOUT TRANSITION FROM SUBSONIC TO SUPERSONIC SPEEDS. Jim Rogers Thompson. January 16, 1950. 36p. diagrs., photos., 2 tabs. (NACA RM L9J27) (Declassified from Confidential, 8/23/54)

The drag and pressure distribution on a body of revolution of fineness ratio 12 were measured by the free-fall method at large scale under actual flight conditions throughout a range of Mach number from 0.75 to 1.27. Analysis shows in detail the mechanism of the abrupt drag rise which occurs near the speed of sound and demonstrates that the theoretical method of NACA TN 1768 satisfactorily predicts the shape of the pressure distribution over the test body at supersonic speeds. Limited information on skin friction is presented.

NACA RM L9K02

INVESTIGATION OF EFFECT OF SPAN AND SPANWISE LOCATION OF PLAIN AND STEPPED SPOILER AILERONS ON LATERAL CONTROL CHARACTERISTICS OF A WING WITH LEADING EDGE SWEPT BACK 51.3°. Jack Fischel and Alexander D. Hammond. January 18, 1950. 59p. diagrs., photos. (NACA RM L9K02) (Declassified from Confidential, 8/23/54)

Contains results and discussion of a low-speed lateral control investigation of a 51.3° sweptback wing equipped with plain and stepped spoiler ailerons having various spans and spanwise locations. The various ailerons were tested on the wing alone and on the wing with a simulated fuselage, an 0.487-span drooped nose, an 0.487-span split flap, and with various combinations thereof through a large angle-of-attack range.

NACA RM L9K03

MAXIMUM-LIFT INVESTIGATION AT MACH NUMBERS FROM 0.05 TO 1.20 OF A WING WITH LEADING EDGE SWEPT BACK 42°. Thomas R. Turner. February 14, 1950. 21p. diagrs. (NACA RM L9K03) (Declassified from Confidential, 8/23/54)

This paper contains the aerodynamic characteristics in pitch up to maximum lift for a reflection-plane model having 42° leading-edge sweep, an aspect ratio of 4, and a taper ratio of 0.625. The Mach number varied from 0.05 to 1.20 with the Reynolds number varying from 350,000 to 5,000,000. The higher Mach numbers were obtained by means of the transonic bump.

NACA RM L9K04a

A STUDY OF THE DYNAMIC STABILITY OF THE BELL X-1 RESEARCH AIRPLANE. Edward C. Polhamus. January 10, 1950. 16p. diagrs., tab. (NACA RM L9K04a) (Declassified from Confidential, 8/23/54)

The period and damping of the lateral oscillation of the Bell X-1 research airplane have been calculated for a range of Mach numbers and wing loadings for an altitude of 30,000 feet. The effect of changes in the magnitude of some of the parameters has been investigated and a comparison with flight results has been made.

NACA RM L9K11

MEASUREMENTS OF AERODYNAMIC CHARACTERISTICS OF A 35° SWEPTBACK NACA 65-009 AIRFOIL MODEL WITH 1/4-CHORD BEVELLED-TRAILING-EDGE FLAP AND TRIM TAB BY THE NACA WING-FLOW METHOD. Harold I. Johnson and B. Porter Brown. January 6, 1950. 68p. diagrs., photo. (NACA RM L9K11) (Declassified from Confidential, 8/23/54)

Contains lift, pitching-moment, and hinge-moment data from wing-flow tests of a low-aspect-ratio sweptback airfoil model having a full-span 1/4-chord bevelled-trailing-edge flap. Mach number range was 0.55 to 1.15. Conclusion is that bevelled trailing edge is undesirable type of aerodynamic balance for large speed range because of nonuniform balancing characteristics at subsonic speeds and loss of balancing effectiveness at low supersonic speeds.

NACA RM L9K22

RESULTS OBTAINED DURING FLIGHTS 1 TO 6 OF THE NORTHROP X-4 AIRPLANE (A.F. NO. 46-677). James T. Matthews, Jr. January 12, 1950. 19p. diagrs., photos., tab. (NACA RM L9K22) (Declassified from Confidential, 8/23/54)

Results are presented for flights 1 to 6 of a Northrop X-4 number 2 semitailless research airplane (A.F. No. 46-677) equipped with NACA instruments. Data presented include time histories of a complete pull-up and several short runs in level and accelerated flight, and the effect of dive-brake extension on longitudinal and lateral trim extension.

NACA RM L9K28

AN INVESTIGATION OF THE SPIN, RECOVERY, AND TUMBLING CHARACTERISTICS OF A 1/20-SCALE MODEL OF THE NORTHROP X-4 AIRPLANE. Lawrence J. Gale, Ira P. Jones, Jr. and Jack H. Wilson. January 4, 1950. 27p. diagrs., photos., 4 tabs. (NACA RM L9K28) (Declassified from Confidential, 8/23/54)

An investigation of the spin, recovery, and tumbling characteristics of a 1/20-scale model of the Northrop X-4 airplane has been conducted in the Langley 20-foot free-spinning tunnel. The effects of control settings and movements upon the erect and inverted spin and recovery characteristics of the model were determined for the model for loading conditions simulating various degrees of exhaustion of fuel in the airplane. An investigation was also made to determine the spin-recovery parachute requirements.

NACA RM L9L05

INVESTIGATION OF THE NACA 4-(4)(06)-057-45A AND NACA 4-(4)(06)-057-45B TWO-BLADE SWEPT PROPELLERS AT FORWARD MACH NUMBERS TO 0.925. James B. Delano and Daniel E. Harrison. February 6, 1950. 44p. diagrs., photos. (NACA RM L9L05) (Declassified from Confidential, 8/23/54)

The paper presents propeller characteristics for the NACA 4-(4)(06)-057-45A and NACA 4-(4)(06)-057-45B two-blade swept propellers for forward Mach numbers up to 0.925 for blade angles of 25°, 55°, 60°, 65°, and 70°. Moderate delays in onset of adverse compressibility effects were obtained through use of large amounts of sweep. The measured delay was approximately 25 percent of the value predicted by the use of simple infinite-span sweep theory.

NACA RM L9L08a

MOTION OF A TRANSONIC AIRPLANE NOSE SECTION WHEN JETTISONED AS DETERMINED FROM WIND-TUNNEL INVESTIGATIONS ON A 1/25-SCALE MODEL. Stanley H. Scher and Lawrence J. Gale. May 26, 1950. 64p. diagrs., photos., tab. (NACA RM L9L08a) (Declassified from Confidential, 8/23/54)

An investigation has been conducted with a 1/25-scale model in the Langley 300 mph 7- by 10-foot tunnel, the Langley free-flight tunnel, and the Langley 20-foot free-spinning tunnel to determine the path and motion of a transonic airplane nose section when jettisoned. The investigation included determination of the probable accelerations that would act on a pilot in the jettisoned nose section.

NACA RM L9L12

PRESSURE DISTRIBUTIONS ON THE BLADE SECTIONS OF THE NACA 10-(3)(066)-033 PROPELLER UNDER OPERATING CONDITIONS. Julian D. Maynard and Maurice P. Murphy. January 24, 1950. 166p. diagrs., photos., 12 tabs. (NACA RM L9L12) (Declassified from Confidential, 8/23/54)

Contains preliminary data obtained by measuring the pressure distributions on eleven blade sections of the NACA 10-(3)(066)-033 propeller having section design lift coefficients of 0.3 and varying in thickness from about 4 percent at the tip to 16 percent at the spinner surface. The pressure distributions

together with the corresponding section normal-force coefficients, chordwise-pressure-force coefficients, and pitching-moment coefficients are presented in the form of tables for a range of angle of attack from about -2° to 11° and for a Mach number range from about 0.3 to 1.2.

NACA RM L9L12a

LATERAL-CONTROL INVESTIGATION OF FLAP-TYPE CONTROLS ON A WING WITH QUARTER-CHORD LINE SWEPT BACK 35°, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Robert F. Thompson. January 25, 1950. 22p. diagrs., tab. (NACA RM L9L12a) (Declassified from Confidential, 8/23/54)

This paper presents the results of an investigation to determine the control-effectiveness characteristics of 30-percent-chord flap-type control surfaces of various spans on a semispan wing-fuselage model by the transonic-bump method. The model employed a wing with the quarter-chord line swept back 35°, an aspect ratio of 4, a taper ratio of 0.6, and an NACA 65A006 airfoil section parallel to the free stream. Rolling moments, pitching moments, and lift were obtained through a Mach number range of 0.6 to 1.20.

NACA RM L9L15

THE TIME LAG BETWEEN FLAP DEFLECTION AND FORCE DEVELOPMENT AT A MACH NUMBER OF 4. Walter F. Lindsey and Edward F. Ulmann. February 13, 1950. 11p. diagr., photos. (NACA RM L9L15) (Declassified from Confidential, 8/23/54)

Presents the results of an investigation at a Mach number of 4 and a Reynolds number of 5×10^6 of the time lag between flap deflection and force development on a rectangular wing having a 9-percent-thick symmetrical circular-arc profile and a 30-percent-chord full-span flap. The lag was found to be less than one-half of a millisecond or less than a 3-1/2 chord movement of the model.

NACA RM L9L16

PRESSURE MEASUREMENTS AT SUPERSONIC SPEEDS ON A SECTION OF A RECTANGULAR WING HAVING AN NACA 65-009 PROFILE. Robert W. Rainey. March 10, 1950. 31p. diagrs., photos., tab. (NACA RM L9L16) (Declassified from Confidential, 8/23/54)

Experimental and predicted pressure distributions are presented for a section of a rectangular wing having an NACA 65-009 profile at $M = 1.62$, 1.93, and 2.40 at Reynolds numbers of 1.07×10^6, 0.97×10^6, and 0.81×10^6, respectively. Integrated normal-force, pitching-moment, and chordwise coefficients, as well as shadowgraphs and a discussion of the character of flow about the model, are reported. Comparison between the aerodynamic characteristics of the NACA 65-009 airfoil and a symmetrical circular-arc airfoil of the same thickness ratio is made.

NACA RM L9L19

FLIGHT INVESTIGATION OF THE EFFECT OF THICKENING THE AILERON TRAILING EDGE ON CONTROL EFFECTIVENESS FOR SWEPTBACK TAPERED WINGS HAVING SHARP- AND ROUND-NOSE SECTIONS. H. Kurt Strass and Edison M. Fields. May 2, 1950. 20p. diagrs., photo., tab. (NACA RM L9L19) (Declassified from Confidential, 8/23/54)

The effect of thickening the trailing edge of an aileron on control effectiveness and drag at transonic and supersonic speeds as determined in flight are presented for a wing having an NACA 0010-64 airfoil section, a taper ratio of 0.455, an aspect ratio of 3.6, sweepback of the quarter-chord of 38.1°, and a trailing edge angle of 17°. The results are compared with a previous investigation of a similar wing having a circular-arc section. The blunt trailing edge eliminated the control reversal obtained with the true-contour ailerons and greatly improved the control effectiveness although at some sacrifice in drag.

NACA RM L9L21a

HYDRODYNAMIC FORCE CHARACTERISTICS OF A STREAMLINE FUSELAGE MODIFIED BY EITHER BREAKER STRIPS OR ROWS OF AIR JETS SIMULATING CHINES. Bernard Weinflash, Charles L. Shuford, Jr. and Kenneth W. Christopher. February 21, 1950. 45p. diagrs., photos. (NACA RM L9L21a) (Declassified from Confidential, 8/23/54)

Force tests were made to determine the effect of trim on the resistance, hydrodynamic lift, and hydrodynamic moment of a streamline fuselage modified by either strips or rows of air jets simulating chines. Tests were also made of the model modified by the strips for three load-on-the-water conditions and for the model with the longitudinal curvature of the after half of the fuselage bottom eliminated.

NACA RM L9L23

PRESSURE DISTRIBUTIONS ON THE BLADE SECTIONS OF THE NACA 10-(3)(049)-033 PROPELLER UNDER OPERATING CONDITIONS. W. H. Gray and Robert M. Hunt. February 14, 1950. 120p. diagrs., 11 tabs. (NACA RM L9L23) (Declassified from Confidential, 8/23/54)

Presents unanalyzed data in tabular form obtained from pressure-distribution measurements on one of a family of five related propellers incorporating 16-series blade sections. Nine radial stations were investigated with a variation of thickness ratio from 2.6 percent to 8.9 percent and covering a section Mach number range from 0.375 to 1.197.

NACA RM L9L23a

AN INVESTIGATION OF SEVERAL NACA 1-SERIES NOSE INLETS WITH AND WITHOUT PROTRUDING CENTRAL BODIES AT HIGH-SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. Robert E. Pendley and Harold L. Robinson. February 21, 1950. 53p. diagrs., photos. (NACA RM L9L23a) (Declassified from Confidential, 8/23/54)

Measurements of pressure distribution, drag, and internal-flow pressure loss are presented for three NACA 1-series nose inlets, two of which were fitted with protruded central bodies. Test Mach number and inlet-velocity ratio ranged from 0.4 to 1.2 and from 0 to 1.34, respectively. Nose-inlet pressure drag at a Mach number of 1.2, and central-body effects on subcritical drag, the supercritical drag rise, and inlet total-pressure loss are discussed.

NACA RM L9L28a

AERODYNAMIC INVESTIGATION AT MACH NUMBER 1.92 OF A RECTANGULAR WING AND TAIL AND BODY CONFIGURATION AND ITS COMPONENTS. Macon C. Ellis, Jr. and Carl E. Grigsby. March 1, 1950. 96p. diagrs., photos., 4 tabs. (NACA RM L9L28a) (Declassified from Confidential, 8/23/54)

An investigation at Mach number 1.92 in the Langley 9-inch supersonic tunnel of a variable body-wing-tail configuration has been made in order to determine and to isolate the aerodynamic effects on each other of the components of the configuration. The body had a fineness ratio of 12.5 with a cylindrical midsection so that the aspect-ratio-4 rectangular wing could be located at three longitudinal positions along the body. The variable-incidence-angle rectangular tail was of the same aspect ratio as the wing, but one-fourth the wing area, and could be located at three vertical positions relative to the plane of the wing. The tests included lift, drag, and pitching-moment measurements of all possible elements and combinations of this model.

NACA RM L50A03

LATERAL-CONTROL INVESTIGATION OF FLAP-TYPE CONTROLS ON A WING WITH UNSWEPT QUARTER-CHORD LINE, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Alexander D. Hammond. March 10, 1950. 20p. diagrs. (NACA RM L50A03) (Declassified from Confidential, 8/23/54)

This paper presents the results of a lateral-control investigation of a 30-percent-chord flap-type control having various spans and spanwise locations on a wing with unswept quarter-chord line, aspect ratio 4, taper ratio 0.6, and an NACA 65A006 airfoil section. Rolling moments, pitching moments, and lift of the semispan wing-fuselage were obtained through a Mach number range of 0.7 to 1.15.

NACA RM L50A03a

AN 8-FOOT AXISYMMETRICAL FIXED NOZZLE FOR SUBSONIC MACH NUMBERS UP TO 0.99 AND FOR A SUPERSONIC MACH NUMBER OF 1.2. Virgil S. Ritchie, Ray H. Wright and Marshall P. Tulin. February 23, 1950. 52p. diagrs., photos., 2 tabs. (NACA RM L50A03a) (Declassified from Confidential, 8/23/54)

The design and operating characteristics of an 8-foot-diameter circular nozzle for Mach number 1.2 and for high-subsonic Mach numbers are discussed. The nozzle was carefully designed and adjusted for boundary-layer displacement. The flow in the subsonic and supersonic test sections was satisfactorily uniform for model testing. Consideration was given to disturbances in the flow, irregularities at the wall, humidity effects, and power requirements.

NACA RM L50A12

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 60°, ASPECT RATIO 2, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Boyd C. Myers, II and Thomas J. King, Jr. February 24, 1950. 31p. diagrs., photos., tab. (NACA RM L50A12) (Declassified from Confidential, 8/23/54)

This paper presents the results of an investigation by the transonic-bump method of a wing-fuselage combination employing a wing with quarter-chord line swept back 60°, aspect ratio 2, taper ratio 0.6, and NACA 65A006 airfoil. Lift, drag, pitching-moment and root-bending-moment characteristics were obtained for the wing-alone and wing-fuselage configurations over a Mach number range from 0.70 to 1.18. In addition, effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were obtained and are presented for a range of tail heights at one tail length. In order to expedite publishing of these data, only a brief analysis has been made.

NACA RM L50A13

PRELIMINARY INVESTIGATION OF A SUBMERGED AIR SCOOP UTILIZING BOUNDARY-LAYER SUCTION TO OBTAIN INCREASED PRESSURE RECOVERY. Mark R. Nicholas and P. Kenneth Pierpont. March 17, 1950. 77p. diagrs., photos., tab. (NACA RM L50A13) (Declassified from Confidential, 8/23/54)

Presents results of low-speed tests of a submerged inlet consisting essentially of a conventional scoop located in a dimple in the fuselage surface. Boundary-layer-control systems investigated are shown to provide important increases in performance. It appears that the flow instability frequently encountered in the case of twin internally coupled inlets will be avoided for design high-speed inlet-velocity ratios as low as 0.5.

NACA RM L50A17

LATERAL-CONTROL INVESTIGATION OF FLAP-TYPE CONTROLS ON A WING WITH QUARTER-CHORD LINE SWEPT BACK 60°, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Raymond D. Vogler. March 2, 1950. 21p. diagrs. (NACA RM L50A17) (Declassified from Confidential, 8/23/54)

This paper presents the results of a lateral-control investigation of a 30-percent-chord flap-type control of various spanwise magnitudes and locations on a wing of 60° of sweepback of the quarter-chord line, an aspect ratio of 4, a taper ratio of 0.6, and an NACA 65A006 airfoil section. Rolling and pitching moments and lift of the semispan wing-fuselage were obtained through a Mach number range of 0.7 to 1.15.

NACA RM L50A18

AERODYNAMIC CHARACTERISTICS OF A WING WITH UNSWEPT QUARTER-CHORD LINE, ASPECT RATIO 2, TAPER RATIO 0.78, AND NACA 65A004 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Edward C. Polhamus and George S. Campbell. March 8, 1950. 17p. diagrs., photos., tab. (NACA RM L50A18) (Declassified from Confidential, 8/23/54)

This paper presents the results of an investigation by the transonic-bump method of a wing having an unswept quarter-chord line, aspect ratio 2, taper ratio 0.78, and NACA 65A004 airfoil. Lift, drag, pitching-moment, and root-bending-moment characteristics were obtained over a Mach number range of from 0.60 to 1.17. Experimental values of lift-curve slope, lateral center of pressure, and drag due to lift are compared with available theory.

NACA RM L50A23

A DISCUSSION OF THE DESIGN OF HIGHLY SWEPT PROPELLER BLADES. Richard T. Whitcomb. May 4, 1950. 31p. diagrs., photos. (NACA RM L50A23) (Declassified from Confidential, 8/23/54)

A description of the two swept propellers investigated in the Langley 8-foot high-speed tunnel is presented, together with the discussions of the numerous assumptions and analyses on which the designs of these propellers are based.

NACA RM L50A26

PRESSURE DISTRIBUTIONS ON THE BLADE SECTIONS OF THE NACA 10-(3)(090)-03 PROPELLER UNDER OPERATING CONDITIONS. Peter J. Johnson. March 22, 1950. 90p. diagrs., 10 tabs. (NACA RM L50A26) (Declassified from Confidential, 8/23/54)

Presents unanalyzed data in tabular form obtained from pressure-distribution measurements on one of a family of five related propellers incorporating NACA 16-series blade sections. Pressure distributions were measured at nine radial stations for which blade-section thickness ratio varied from 0.300 to 0.053 and section Mach number varied from 0.28 to 1.18.

NACA RM L50A30

EXPLORATORY INVESTIGATION OF LEADING-EDGE CHORD-EXTENSIONS TO IMPROVE THE LONGITUDINAL STABILITY CHARACTERISTICS OF TWO 52° SWEPTBACK WINGS. G. Chester Furlong. March 10, 1950. 32p. diagrs., photo. (NACA RM L50A30) (Declassified from Confidential, 8/23/54)

Results are presented of exploratory tests obtained with leading-edge wing chord-extensions on two 52° sweptback wings for the purpose of obtaining satisfactory longitudinal stability through the lift range. Both wings exhibit a vortex flow similar to that which has been observed on triangular wings. One wing of aspect ratio 2.8 has circular-arc airfoil sections, and the other wing of aspect ratio 2.9 has NACA 64_1-112 airfoil sections. The tests were conducted at Reynolds numbers in the vicinity of 6.0×10^6.

NACA RM L50A31

WING-FLOW MEASUREMENTS OF LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A CANARD AIRPLANE CONFIGURATION WITH A 45° SWEPTBACK WING AND A TRIANGULAR ALL-MOVABLE CONTROL SURFACE. Harold L. Crane and James J. Adams. August 25, 1950. 53p. diagrs., photo. (NACA RM L50A31) (Declassified from Confidential, 8/23/54)

Presented are lift, pitching-moment, rolling-moment, and drag measurements for a semispan canard configuration for a Mach number range of 0.55 to 1.14 at Reynolds numbers between 225,000 to 575,000. The configuration consisted of a 45° sweptback untapered wing and a triangular control surface mounted on a body of fineness ratio 13.5. The aerodynamic center shift with increasing Mach number was small and the effectiveness of the control surface increased gradually with Mach number with the result that the longitudinal trim and control characteristics in the transonic speed range at low lift coefficients were desirable. Also included are calculated trim curves for various loading conditions and calculated aeroelastic effects.

NACA RM L50B02a

INVESTIGATION OF A SIMPLE DEVICE FOR PREVENTING SEPARATION DUE TO SHOCK AND BOUNDARY-LAYER INTERACTION. Coleman duP. Donaldson. November 29, 1950. 34p. diagrs., photos. (NACA RM L50B02a) (Declassified from Confidential, 8/23/54)

Results are presented of a preliminary investigation of vortex generators introduced into the region of boundary layer to increase the turbulent mixing, in an attempt to prevent separation due to boundary-layer and shock interaction. Prevention of such separation and some of its adverse effects up to Mach numbers ahead of the shock of the order of 1.4 appears possible by means of this simple device. Preliminary flight tests show that this method is effective in controlling shock-induced separation on the wing of an airplane at high speed.

NACA RM L50B03a

AERODYNAMIC CHARACTERISTICS OF A WING WITH QUARTER-CHORD LINE SWEPT BACK 45°, ASPECT RATIO 6, TAPER RATIO 0.6, AND NACA 65A009 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Kenneth P. Spreemann, William D. Morrison, Jr. and Thomas B. Pasteur, Jr. April 6, 1950. 33p. diagrs., photos., tab. (NACA RM L50B03a) (Declassified from Confidential, 8/23/54)

This paper presents the results of an investigation by the transonic-bump method of a wing alone and a wing-fuselage combination employing a wing with quarter-chord line swept back 45°, aspect ratio 6, taper ratio 0.6, and NACA 65A009 airfoil section. Lift, drag, pitching moment, and root bending moment were obtained for the wing-alone and wing-fuselage configurations over a Mach range of 0.60 to 1.18 and through an angle-of-attack range of -4° to 10°. Effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were also obtained and are presented for a range of tail heights at one tail length.

NACA RM L50B10

THE DAMPING IN ROLL OF ROCKET-POWERED TEST VEHICLES HAVING RECTANGULAR WINGS WITH NACA 65-006 AND SYMMETRICAL DOUBLE-WEDGE AIRFOIL SECTIONS OF ASPECT RATIO 4.5. Albert E. Dietz and James L. Edmondson. March 29, 1950. 12p. diagrs. (NACA RM L50B10) (Declassified from Confidential, 8/23/54)

Experimental determination of damping in roll through a Mach range of 0.85 to 1.45 was conducted for two free-flight models having rectangular wing plan forms and an aspect ratio of 4.5. One model had wings with NACA 65-006 airfoil sections and the other model had wings with 6-percent-thick modified double-wedge airfoil sections.

NACA RM L50B21

PRESSURE DISTRIBUTIONS ON THE BLADE SECTIONS OF THE NACA 10-(5)(066)-03 PROPELLER UNDER OPERATING CONDITIONS. Albert J. Evans and Wallace Luchuk. April 18, 1950. 99p. diagrs., 10 tabs. (NACA RM L50B21) (Declassified from Confidential. 8/23/54)

Presents unanalyzed data in tabular form from pressure distribution measurements on one of a family of five related propellers incorporating NACA 16-series sections. Nine radial stations were investigated which had design lift coefficients of 0.50 and varied in thickness from 16 percent to 4 percent of the chord. The Mach number varied from 0.4 to 1.15.

NACA RM L50C03

PRESSURE DISTRIBUTIONS ON THE BLADE SECTIONS OF THE NACA 10-(0)(066)-03 PROPELLER UNDER OPERATING CONDITIONS. Seymour Steinberg and Robert W. Milling. May 18, 1950. 89p. diagrs., 11 tabs. (NACA RM L50C03) (Declassified from Confidential, 8/23/54)

Presents unanalyzed data in tabular form obtained from pressure-distribution measurements on one of five related propellers incorporating NACA 16-series blade sections. Pressure distributions were measured at nine radial stations for which blade-section thickness ratio varied from 0.04 to 0.10 and section Mach number varied from 0.35 to 1.14.

NACA RM L50C16

AERODYNAMIC CHARACTERISTICS OF A WING WITH UNSWEPT QUARTER-CHORD LINE, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A004 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Boyd C. Myers, II and James W. Wiggins. May 8, 1950. 31p. diagrs., photos., tab. (NACA RM L50C16) (Declassified from Confidential, 8/23/54)

This paper presents the results of an investigation by the transonic-bump method of a wing and wing-fuselage combination employing a wing with unswept quarter-chord line, aspect ratio 4, taper ratio 0.6, and NACA 65A004 airfoil section parallel to free stream. Lift, drag, pitching-moment, and root-bending-moment characteristics were obtained for the two configurations over a Mach number range from about 0.60 to 1.15. In addition, effective downwash angles and dynamic-pressure characteristics in the region of the tail plane were obtained and presented for a range of tail heights at one tail length.

NACA RM L50C21

AERODYNAMIC CHARACTERISTICS WITH FIXED AND FREE TRANSITION OF A MODIFIED DELTA WING IN COMBINATION WITH A FUSELAGE AT HIGH SUBSONIC SPEEDS. Edward C. Polhamus and Thomas J. King, Jr. May 2, 1950. 19p. diagrs., photos. (NACA RM L50C21) (Declassified from Confidential, 8/23/54)

An investigation has been made in the Langley high-speed 7- by 10-foot tunnel to determine the aerodynamic characteristics at high subsonic speeds of a modified delta wing with an aspect ratio of 3, a taper ratio of 0.313, a sweepback of 27.7°, and an NACA 64_1A012 airfoil section in combination with a fuselage. Lift, drag, and pitching-moment characteristics with free- and fixed-transition are presented through a Mach number range of 0.40 to 0.90.

NACA RM L50C22

AERODYNAMIC AND LATERAL-CONTROL CHARACTERISTICS OF A 1/28-SCALE MODEL OF THE BELL X-1 AIRPLANE WING-FUSELAGE COMBINATION. TRANSONIC-BUMP METHOD. Vernard E. Lockwood. May 5, 1950. 28p. diagrs., tab. (NACA RM L50C22) (Declassified from Confidential, 8/23/54)

This paper presents the lateral-control characteristics and the pitching-moment characteristics of a 1/28-scale model of the X-1 wing-fuselage configuration. The tests were made in the transonic speed range from a Mach number of 0.60 to 1.15 in the Langley high-speed 7- by 10-foot tunnel utilizing the transonic bump. Comparisons have been made between the wind-tunnel results and the flight-test results of the rolling effectiveness, pitching-moment

characteristics, and lateral centers of pressure. The estimations of rolling effectiveness were made using the damping in roll and aileron effectiveness experimentally determined.

NACA RM L50C28

MAXIMUM-LIFT INVESTIGATION OF A 1/40-SCALE X-1 AIRPLANE WING AT MACH NUMBERS FROM 0.60 TO 1.15. Thomas R. Turner. April 21, 1950. 18p. diagrs. (NACA RM L50C28) (Declassified from Confidential, 8/23/54)

This paper contains the lift, drag, and pitching-moment characteristics up to a maximum lift of a 1/40-scale model of the X-1 airplane wing (8-percent-thick wing), also some comparisons with flight results. The Mach number varied from 0.60 to 1.15 with the Reynolds number varying from 415,000 to 533,000.

NACA RM L50D05

AERODYNAMIC CHARACTERISTICS AT A MACH NUMBER OF 1.25 OF A 6-PERCENT-THICK TRIANGULAR WING AND 6- AND 9-PERCENT-THICK TRIANGULAR WINGS IN COMBINATION WITH A FUSELAGE. WING ASPECT RATIO 2.31, BICONVEX AIRFOIL SECTIONS. Albert W. Hall and Garland J. Morris. May 5, 1950. 22p. diagrs., photo., 2 tabs. (NACA RM L50D05) (Declassified from Confidential, 8/23/54)

Tests were made by the NACA wing-flow method on two wing-fuselage models with delta wings of aspect ratio 2.31, 6- and 9-percent-thick biconvex sections, and on the 6-percent-thick wing alone. Lift, drag, pitching-moment, and angle-of-attack measurements are presented for these configurations and some comparisons are made with subsonic and supersonic data from other sources. The test Mach number was 1.25 and the Reynolds number was about 8.8×10^5.

NACA RM L50D19

LOW-SPEED INVESTIGATION OF DEFLECTABLE WING-TIP ELEVATORS ON A LOW-ASPECT-RATIO UNTAPERED 45° SWEPTBACK SEMISPAN WING WITH AND WITHOUT AN END PLATE. Jack Fischel and William M. O'Hare. June 1, 1950. 21p. diagrs., photo. (NACA RM L50D19) (Declassified from Confidential, 8/23/54)

Results and discussion are presented of a low-speed investigation of triangular- and parallelogrammic-plan-form deflectable wing-tip elevators on an untapered 45° sweptback semispan wing with and without a rectangular end plate (simulating a vertical fin) mounted on the wing inboard of the elevators. Lift, drag, and pitching-moment data were obtained through a large angle-of-attack range and a large elevator-deflection range for each elevator plan form on the plain wing and the wing with end plate. Estimated pitching-moment data were compared with experimental data for the two elevator plan forms.

NACA RM L50D20

FLIGHT INVESTIGATION OF THE AILERON CHARACTERISTICS OF THE DOUGLAS D-558-I AIRPLANE (BUAERO NO. 37972) AT MACH NUMBERS BETWEEN 0.6 AND 0.89. Jim Rogers Thompson, William S. Roden and John M. Eggleston. May 26, 1950. 23p. diagrs., photos., tab. (NACA RM L50D20) (Declassified from Confidential, 8/23/54)

Measurements of the aileron effectiveness of the Douglas D-558-I airplane (BuAero No. 37972) indicate that there is no change in aileron effectiveness with Mach number between Mach numbers of 0.6 and 0.89.

NACA RM L50D21

INVESTIGATION OF THE NACA 3-(3)(05)-05 EIGHT-BLADE DUAL-ROTATING PROPELLER AT FORWARD MACH NUMBERS TO 0.925. Robert J. Platt, Jr. and Robert A. Shumaker. June 19, 1950. 42p. diagrs., photo. (NACA RM L50D21) (Declassified from Confidential, 8/23/54)

Force-test results are presented for the NACA 3-(3)(05)-05 eight-blade dual propeller, which was designed for a blade angle of approximately 75°. The tests covered a blade-angle range from 55° to 80° at Mach numbers to 0.925. Some data on the effect of small changes in the rear-propeller blade angle are included. Good efficiencies were obtained at high subsonic Mach numbers by operation at high blade angles.

NACA RM L50D24

A TECHNIQUE UTILIZING ROCKET-PROPELLED TEST VEHICLES FOR THE MEASUREMENT OF THE DAMPING IN ROLL OF STING-MOUNTED MODELS AND SOME INITIAL RESULTS FOR DELTA AND UNSWEPT TAPERED WINGS. William M. Bland, Jr. and Carl A. Sandahl. June 13, 1950. 31p. diagrs., photos., tab. (NACA RM L50D24) (Declassified from Confidential, 8/23/54)

A technique with which the damping in roll of sting-mounted models can be measured over the subsonic, transonic, and supersonic speed range with rocket-propelled test vehicles is described. Initial results for delta and unswept tapered wings are presented and compared with theory.

NACA RM L50D28

EFFECT OF COMPRESSIBILITY AND CAMBER AS DETERMINED FROM AN INVESTIGATION OF THE NACA 4-(3)(08)-03 AND 4-(5)(08)-03 TWO-BLADE PROPELLERS UP TO FORWARD MACH NUMBERS OF 0.925. Melvin M. Carmel, Francis G. Morgan, Jr. and Domenic A. Coppolino. June 29, 1950. 92p. diagrs., photo. (NACA RM L50D28) (Declassified from Confidential, 8/23/54)

Section-thrust-coefficient data are presented for forward Mach numbers up to 0.925 for the NACA 4-(3)(08)-03 propeller for blade angles of 55° to 65° and for the NACA 4-(5)(08)-03 propeller for blade angles of 40° to 65°. A comparison of these results with force-test results is made.

NACA RM L50E09

LATERAL-CONTROL INVESTIGATION OF FLAP-TYPE AND SPOILER-TYPE CONTROLS ON A WING WITH QUARTER-CHORD-LINE SWEEPBACK OF 60°, ASPECT RATIO 2, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Alexander D. Hammond. July 18, 1950. 26p. diagrs. (NACA RM L50E09) (Declassified from Confidential, 8/23/54)

This paper presents the results of a lateral-control investigation of a 30-percent-chord flap-type control and a plain spoiler-type control of 5-percent-chord projection, each having various span and spanwise locations on a wing with a quarter-chord line swept back 60°, aspect ratio 2, taper ratio 0.6, and an NACA 65A006 airfoil section parallel to free stream. Rolling and pitching moments and lift of the semispan wing-fuselage were obtained through a Mach number range of 0.17 to 1.15 with flap-type controls, and lift, drag, pitching moment, rolling moment, and yawing moment of the semispan wing-fuselage were obtained through a Mach number range of 0.6 to 1.15 with the spoiler-type controls.

NACA RM L50E19a

FLIGHT INVESTIGATION AT MACH NUMBERS FROM 0.6 to 1.7 TO DETERMINE DRAG AND BASE PRESSURES ON A BLUNT-TRAILING-EDGE AIRFOIL AND DRAG OF DIAMOND AND CIRCULAR-ARC AIRFOILS AT ZERO LIFT. John D. Morrow and Ellis Katz. August 11, 1950. 25p. diagrs., photos. (NACA RM L50E19a) (Declassified from Confidential, 8/23/54)

Results of an exploratory free-flight investigation at zero lift of several rocket-powered drag-research models having rectangular 6-percent-thick wings are presented for a Mach number range of 0.6 to 1.7. Wings having diamond, circular-arc, and blunt-trailing-edge airfoil sections were tested. Pressures over the base of the blunt-trailing-edge airfoil were measured. The drags of all the models were measured and are compared with theory in this paper.

NACA RM L50E26

DAMPING IN ROLL OF RECTANGULAR WINGS OF SEVERAL ASPECT RATIOS AND NACA 65A-SERIES AIRFOIL SECTIONS OF SEVERAL THICKNESS RATIOS AT TRANSONIC AND SUPERSONIC SPEEDS AS DETERMINED WITH ROCKET-POWERED MODELS. James L. Edmondson. August 24, 1950. 16p. diagrs. (NACA RM L50E26) (Declassified from Confidential, 8/23/54)

The damping in roll has been determined for a series of rectangular wings of various aspect ratios and thickness ratios through use of rocket-powered models and the canted-nozzle technique. An empirical thickness correction factor has been derived to be used with existing linear supersonic damping-in-roll theory to allow closer prediction of experimental damping for limited cases.

NACA RM L50F01

RESULTS OF FLIGHT TESTS TO DETERMINE THE ZERO-LIFT DRAG CHARACTERISTICS OF A 60° DELTA WING WITH NACA 65-006 AIRFOIL SECTION AND VARIOUS DOUBLE-WEDGE SECTIONS AT MACH NUMBERS FROM 0.7 TO 1.6. Clement J. Welsh. August 11, 1950. 15p. diagrs., photo. (NACA RM L50F01) (Declassified from Confidential, 8/23/54)

Results of an exploratory free-flight investigation at zero lift of several rocket-powered drag research models equipped with 60° sweptback delta wings are presented for a Mach number range from about 0.70 to 1.60. The airfoil sections tested included the NACA 65-006 and a series of double-wedge sections with various positions of maximum thickness.

NACA RM L50F19

LOW-SPEED TESTS OF A MODEL SIMULATING THE PHENOMENON OF CONTROL-SURFACE BUZZ. William H. Phillips and James J. Adams. August 16, 1950. 16p. diagrs., photo. (NACA RM L50F19) (Declassified from Confidential, 8/23/54)

Low-speed tests have been made of an airfoil model with a freely hinged flap connected to spoilers which passed through slots in the airfoil ahead of the hinge line. Under certain conditions, continuous oscillations of the flap, similar to buzz, were obtained. This result indicates that flow separation may be an important factor in producing buzz at transonic speeds.

NACA RM L50F19a

SPIN AND RECOVERY CHARACTERISTICS OF A MODEL OF A FIGHTER TYPE OF AIRPLANE WITHOUT A HORIZONTAL TAIL AND HAVING EITHER A SINGLE VERTICAL TAIL OR TWIN VERTICAL TAILS. Lawrence J. Gale and Norman E. Pumphrey. July 25, 1950. 23p. diagrs., photos., 2 tabs. (NACA RM L50F19a) (Declassified from Confidential, 8/23/54)

The investigation indicated similar spin and recovery characteristics for either tail configuration tested at a given mass distribution. For a mass distribution chiefly along the wings, the vertical tail surfaces were not adequate for recovery from the spin. When the mass was distributed chiefly along the fuselage, however, either vertical-tail configuration, when in a rearward position, was effective in satisfactorily terminating the spin.

NACA RM L50F26
National Advisory Committee for Aeronautics. MEASUREMENTS OF THE EFFECT OF TRAILING-EDGE THICKNESS ON THE ZERO-LIFT DRAG OF THIN LOW-ASPECT-RATIO WINGS. John D. Morrow. August 14, 1950. 12p. diagrs., photo. (NACA RM L50F26) (Declassified from Confidential, 8/23/54)

Results of an exploratory free-flight investigation at zero lift of several rocket-powered drag-research models having 4-percent-thick wings of 0.423 taper ratio are presented for a Mach number range of 0.7 to 1.6. Four wings having trailing edges of different thickness were tested. The drag of all the models was measured and is compared with calculated values in this paper.

NACA RM L50F26a

SOME CALCULATIONS OF THE LATERAL RESPONSE OF TWO AIRPLANES TO ATMOSPHERIC TURBULENCE WITH RELATION TO THE LATERAL SNAKING PROBLEM. John D. Bird. August 25, 1950. 24p. diagrs., 2 tabs. (NACA RM L50F26a) (Declassified from Confidential, 8/23/54)

Calculations are made of the lateral response to representative time histories of atmospheric turbulence for two airplanes having widely different dynamic properties; explanations for their difference in behavior are given. The results are discussed in relation to lateral snaking.

NACA RM L50F30

A THEORETICAL INVESTIGATION OF THE INFLUENCE OF AUXILIARY DAMPING IN PITCH ON THE DYNAMIC CHARACTERISTICS OF A PROPORTIONALLY CONTROLLED SUPERSONIC CANARD MISSILE CONFIGURATION. Walter C. Nelson and Anthony L. Passera. August 25, 1950. 46p. diagrs., photo., 3 tabs. (NACA RM L50F30) (Declassified from Confidential, 8/23/54)

A theoretical investigation is presented of the dynamic characteristics of a supersonic canard missile configuration with auxiliary damping in pitch obtained from rate gyro-servo control. Variations in Mach number, altitude, and static margin are considered. Satisfactory system performance is obtained throughout a Mach number and altitude range when additional damping is included in the missile.

NACA RM L50F30a

FLIGHT TESTS AT SUPERSONIC SPEEDS TO DETERMINE THE EFFECT OF TAPER ON THE ZERO-LIFT DRAG OF SWEPTBACK LOW-ASPECT-RATIO WINGS. Murray Pittel. September 5, 1950. 23p. diagrs., photos. (NACA RM L50F30a) (Declassified from Confidential, 8/23/54)

Comparison of experimental flight-test results with theoretical calculations to determine the effect of wing taper and aspect ratio on the zero-lift drag of wings with thin double-wedge sections at supersonic speeds is presented.

NACA RM L50G03

INVESTIGATION OF FLAP-TYPE AILERONS ON AN UNTAPERED WING HAVING AN ASPECT RATIO OF 3.7, 45° SWEEPBACK, AND AN NACA 65A009 AIRFOIL SECTION. TRANSONIC-BUMP METHOD. Richard G. MacLeod. August 23, 1950. 18p. diagrs. (NACA RM L50G03) (Declassified from Confidential, 8/23/54)

This paper presents the results of an investigation to determine the lateral control characteristics of 20-percent-chord flap-type control surfaces of various spans on a semispan wing-fuselage model by the transonic-bump method. The model employed a wing with a sweepback of 45°, an aspect ratio 3.7, a taper ratio of 1.0, and an NACA 65A009 airfoil section parallel to the free stream. Rolling moments were obtained through a small range of angle of attack and control-surface deflections. Lift data on the complete model are also included. The experimental results were in good agreement with those predicted from low-speed theory and other experimental data at a Mach number of 0.6, and the relative spanwise effectiveness of the aileron remained fairly constant throughout the Mach number range tested.

NACA RM L50G11

LOW-SPEED STATIC STABILITY CHARACTERISTICS OF A CANARD MODEL WITH A 45° SWEPTBACK WING AND A 60° TRIANGULAR HORIZONTAL CONTROL SURFACE. John W. Draper. September 6, 1950. 43p. diagrs., photo., 2 tabs. (NACA RM L50G11) (Declassified from Confidential, 8/23/54)

This paper contains results of an investigation made to determine the low-speed static stability characteristics of a canard model having a 45° sweptback untapered wing and a 60° triangular-plan-form horizontal control surface.

NACA RM L50G13a

INVESTIGATION AT TRANSONIC SPEEDS OF A 35-PERCENT-CHORD AILERON ON A TAPERED WEDGE-TYPE WING OF ASPECT RATIO 2.5 WITH AND WITHOUT A FUSELAGE. Thomas R. Turner and Joseph E. Fikes. September 8, 1950. 25p. diagrs. (NACA RM L50G13a) (Declassified from Confidential, 8/23/54)

This paper presents the results of an investigation to determine the effects of fuselage diameter on some of the aerodynamic characteristics of an unswept wing having a modified double-wedge section, an aspect ratio of 2.5, and a taper ratio of 0.625. Rolling moment coefficients for a 35-percent-chord aileron of various spans along with some lift, drag, and pitching moment coefficient data are presented for the wing with a fuselage of two different diameters and without a fuselage through a Mach number range from 0.60 to 1.18. Estimated and experimental values of aileron effectiveness are presented at a Mach number of 0.60.

NACA RM L50G14

AERODYNAMIC CHARACTERISTICS AT A MACH NUMBER OF 1.38 OF FOUR WINGS OF ASPECT RATIO 4 HAVING QUARTER-CHORD SWEEP ANGLES OF 0°, 35°, 45°, AND 60°. William B. Kemp, Jr., Kenneth W. Goodson and Robert A. Booth. October 10, 1950. 41p. diagrs., photos., tab. (NACA RM L50G14) (Declassified from Confidential, 8/23/54)

This paper presents a description of the Langley 6-inch supersonic tunnel together with the results of an investigation made at a Mach number of 1.38 of a series of wings having an aspect ratio 4, taper ratio 0.6, and an NACA 65A006 airfoil section. Lift, drag, pitching-moment, and bending-moment data were obtained for wing alone and wing-body configurations. Comparisons are made between experimental and theoretical lift-curve slopes and stability characteristics.

NACA RM L50G14a

THE EXTERNAL-SHOCK DRAG OF SUPERSONIC INLETS HAVING SUBSONIC ENTRANCE FLOW. Louis M. Nucci. December 20, 1950. 28p. diagrs., photos. (NACA RM L50G14a) (Declassified from Confidential, 8/23/54)

The external-shock drag at a Mach number of 2.70 has been determined by two methods for a circular inlet having low external compression at various mass-flow conditions and for a circular inlet having high external compression. The results indicate a large increase in external shock drag for both inlets at subdesign mass flows, with the drag of the external compression type being considerably higher for comparable mass-flow reduction than that of the inlet having low external compression. A simple approximate method of calculating the external-shock drag is described which is more easily applied than the procedure using characteristics if the entering mass flow and the shock configuration are both known.

NACA RM L50G18

THE CALCULATION OF THE PATH OF A JETTISONABLE NOSE SECTION. Roscoe H. Goodwin. September 7, 1950. 35p. diagrs. (NACA RM L50G18) (Declassified from Confidential, 8/23/54)

A method is presented for calculating the path of a jettisonable nose section at any speed by means of successive approximations (solved graphically) using static aerodynamic characteristics. Comparisons with experimentally determined paths are presented, and the method is applied to the problem of finding the path of a nose section that is jettisoned by use of rockets.

NACA RM L50G24

FLIGHT MEASUREMENTS OF DRAG AND BASE PRESSURE OF A FIN-STABILIZED PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT DIFFERENT REYNOLDS NUMBERS AND AT MACH NUMBERS FROM 0.9 TO 3.3. H. Herbert Jackson, Charles B. Rumsey and Leo T. Chauvin. September 1, 1950. 21p. diagrs., photos. (NACA RM L50G24) (Declassified from Confidential, 8/23/54)

Free-flight tests at supersonic speeds have been made to determine the Reynolds number effects on total drag and base drag of a fin-stabilized parabolic-arc body of revolution having a body fineness ratio of 12.2 and designated the NACA RM-10 configuration. The Reynolds number range of 14×10^6 to 210×10^6 was obtained by testing full-scale and half-scale models through the Mach number range from 0.9 to 3.3.

NACA RM L50H03

PROPELLER SECTION AERODYNAMIC CHARACTERISTICS AS DETERMINED BY MEASURING THE SECTION SURFACE PRESSURES ON AN NACA 10-(3)(08)-03 PROPELLER UNDER OPERATING CONDITIONS. Albert J. Evans. November 8, 1950. 162p. diagrs., 10 tabs. (NACA RM L50H03) (Declassified from Confidential, 8/23/54)

This investigation presents propeller section aerodynamic characteristics obtained by measurement of the section surface pressure distribution at nine radial stations on an operating propeller blade. The results are compared with results from tests with two-dimensional airfoils and cover a range of Mach numbers from 0.20 to 1.15 for angles of attack from -1° to 12° for NACA 16-series airfoils.

NACA RM L50H07

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS AT HIGH-SUBSONIC SPEEDS OF TWO MODELS OF A TRANSONIC RESEARCH AIRPLANE WITH WINGS AND HORIZONTAL TAILS OF ASPECT RATIOS 4.2 AND 2. Arvo A. Luoma and John B. Wright. September 29, 1950. 134p. diagrs., photos., 3 tabs. (NACA RM L50H07) (Declassified from Confidential, 8/23/54)

This paper contains longitudinal stability and control characteristics of two 1/16-scale models of a transonic research airplane tested with no nose-inlet flow. Aspect ratio was the main variable. Various horizontal-tail incidences and elevator deflections were tested. The tests were made up to a Mach number of approximately 0.95 in the Langley 8-foot high-speed tunnel.

NACA RM L50H09

MEASUREMENTS OF AERODYNAMIC CHARACTERISTICS OF A 35° SWEPTBACK NACA 65-009 AIRFOIL MODEL WITH 1/4-CHORD FLAP HAVING A 31-PERCENT-FLAP-CHORD OVERHANG BALANCE BY THE NACA WING-FLOW METHOD. Harold I. Johnson and Harold R. Goodman. September 25, 1950. 38p. diagrs., photo. (NACA RM L50H09) (Declassified from Confidential, 8/23/54)

Lift, pitching-moment, and hinge-moment data obtained from wing-flow tests of a low-aspect-ratio sweptback-airfoil model having a full-span 1/4-chord overhang-balanced flap are presented. Mach number range was 0.55 to 1.15. Comparisons are made with previously unpublished data from tests of a plain-flap model. Conclusion is that 31-percent-flap-chord overhang balance tested was relatively ineffective for reducing hinge moments below a Mach number of 1.00 and totally ineffective between Mach numbers of 1.00 and 1.15.

NACA RM L50H11

EFFECTS OF SWEEP ON THE MAXIMUM-LIFT CHARACTERISTICS OF FOUR ASPECT-RATIO-4 WINGS AT TRANSONIC SPEEDS. Thomas R. Turner. October 3, 1950. 25p. diagrs. (NACA RM L50H11) (Declassified from Confidential, 8/23/54)

An investigation at transonic speeds has been made to determine the effect of wing sweep on the maximum lift characteristics of a series of wings having an aspect ratio of 4, a taper ratio of 0.6, and the quarter-chord line swept back 0°, 35°, 45°, and 60°. The Mach number varied from 0.61 to 1.20 with a Reynolds number variation from 380,000 to 460,000. Lift data are presented from approximately zero lift to beyond maximum lift. Drag and pitching-moment data are also presented.

NACA RM L50H15

LOW-SPEED INVESTIGATION OF A SEMISUBMERGED AIR SCOOP WITH AND WITHOUT BOUNDARY-LAYER SUCTION. P. Kenneth Pierpont and Robert R. Howell. February 23, 1951. 46p. diagrs., photos., 2 tabs. (NACA RM L50H15) (Declassified from Confidential, 8/23/54)

This investigation presents results at low-speed tests of a half-submerged inlet consisting of a conventional scoop located in a depression in the fuselage surface. Boundary-layer-control systems investigated are shown to provide increases in impact-pressure ratio up to 8 percent at $V_i/V_O = 0.6$. The impact-pressure recovery of a partly submerged inlet appears to exceed that of a submerged inlet in the inlet-velocity-ratio range suitable for high-speed operation.

NACA RM L50H22

TRANSONIC DRAG CHARACTERISTICS OF A WING-BODY COMBINATION USING A THIN TAPERED WING OF 45° SWEEPBACK. Max C. Kurbjun and Stanley Faber. September 28, 1950. 14p. diagrs., photo., tab. (NACA RM L50H22) (Declassified from Confidential, 8/23/54)

Contains drag measurements by the free-fall method for a wing-body combination and its components employing a wing of 0.2 taper ratio, NACA 65003 airfoil section (perpendicular to midchord line), 45° sweepback (midchord line), and a fineness-ratio-12 body.

NACA RM L50H23

PRELIMINARY EMPIRICAL DESIGN REQUIREMENTS FOR THE PREVENTION OF TUMBLING OF AIRPLANES HAVING NO HORIZONTAL TAILS. Robert L. Bryant. October 11, 1950. 23p. diagrs., 2 tabs. (NACA RM L50H23) (Declassified from Confidential, 8/23/54)

An investigation has been made of the design characteristics and loadings that are conducive to the tumbling of airplanes that have no horizontal tails. Preliminary empirical design requirements based on model tests of 18 different configurations are presented. A brief explanation of the phenomenon of tumbling is appended.

NACA RM L50H24

AN INVESTIGATION OF THREE TRANSONIC FUSELAGE AIR INLETS AT MACH NUMBERS FROM 0.4 TO 0.94 AND AT A MACH NUMBER OF 1.19. Robert E. Pendley, Harold L. Robinson and Claude V. Williams. November 7, 1950. 51p. diagrs., photos., 3 tabs. (NACA RM L50H24) (Declassified from Confidential, 8/23/54)

Measurements of internal-flow pressure recovery, external-surface pressures, and external drag are presented for three fuselage-side inlets designed for use at transonic speeds. The test Mach number and inlet-velocity ratio ranged from 0.4 to 1.19 and from 0 to 1.9, respectively. The investigation showed that the maximum value of the impact-pressure recovery was high at all Mach numbers. The use of a higher critical Mach number external shape increased the supercritical drag-rise Mach number, decreased the supercritical drag, and reduced the drag at the supersonic Mach number.

NACA RM L50H28a

EFFECT OF AN END PLATE ON THE AERODYNAMIC CHARACTERISTICS OF A 20.55° SWEPTBACK WING WITH AN ASPECT RATIO OF 2.67 AND A TAPER RATIO OF 0.5. TRANSONIC-BUMP METHOD. James M. Watson. December 21, 1950. 15p. diagrs., photo. (NACA RM L50H28a) (Declassified from Confidential, 8/23/54)

This paper contains the results of an investigation of two wings having an aspect ratio of 2.67, a sweepback of 20.55°, and a taper ratio of 0.5, one wing with and one wing without an end plate. A Mach number range of 0.60 to 1.18 was attained by use of the transonic-bump technique.

NACA RM L50H30a

DAMPING IN YAW AND STATIC DIRECTIONAL STABILITY OF A CANARD AIRPLANE MODEL AND OF SEVERAL MODELS HAVING FUSELAGES OF RELATIVELY FLAT CROSS SECTION. Joseph L. Johnson. October 16, 1950. 20p. diagrs., tab. (NACA RM L50H30a) (Declassified from Confidential, 8/23/54)

Contains results of damping-in-yaw and static-directional-stability tests for flat-fuselage models having major axis horizontal and vertical, for a flat-fuselage model with major axis horizontal in combination with a 45° sweptback wing, and for a canard model having a triangular horizontal control surface and a 45° sweptback wing. The effect of a vertical tail located at the rear of the fuselage was determined for each model investigated.

NACA RM L50I01

LOW-SPEED WIND-TUNNEL INVESTIGATION OF A TRIANGULAR SWEPTBACK AIR INLET IN THE ROOT OF A 45° SWEPTBACK WING. Arvid L. Keith, Jr. and Jack Schiff. November 6, 1950. 71p. diagrs., photos., 5 tabs. (NACA RM L50I01) (Declassified from Confidential, 8/23/54)

Results of a low-speed study of a 45° sweptback wing-root air-inlet configuration believed suitable for transonic speed airplanes are presented. The inlet configuration lift and drag characteristics are compared with those of a basic model. Boundary-layer growth along the fuselage nose, inlet total-pressure recoveries, and static-pressure distributions over the inlet and wing surfaces are presented for wide ranges of inlet-velocity ratio and angle of attack.

NACA RM L50I05

EFFECTS ON THE LATERAL OSCILLATION OF FIXING THE RUDDER AND REFLEXING THE FLAPS ON THE BELL X-1 AIRPLANE. Hubert M. Drake. December 11, 1950. 14p. diagrs., photo. (NACA RM L50I05) (Declassified from Confidential, 8/23/54)

In flight tests of the Bell X-1 airplane at a Mach number of 0.85 it has been found that fixing the rudder reduced the amplitude of the snaking oscillation, but did not eliminate it. It was also found that reflexing the wing flaps to change the inclination of the principal axis of inertia increased the dynamic lateral stability, but had only a small effect on the snaking oscillation.

NACA RM L50I08a

FLIGHT INVESTIGATION AT MACH NUMBERS FROM 0.8 TO 1.5 TO DETERMINE THE EFFECTS OF NOSE BLUNTNESS ON THE TOTAL DRAG OF TWO FIN-STABILIZED BODIES OF REVOLUTION. Roger G. Hart. October 16, 1950. 12p. diagrs., photos., 2 tabs. (NACA RM L50I08a) (Declassified from Confidential, 8/23/54)

Values of total-drag coefficient were measured for two fin-stabilized, blunt-nose bodies of revolution in free flight at Mach numbers from 0.8 to 1.5. The blunt-nose bodies were designed by rounding off the sharp noses of bodies, having nose fineness ratios of about 3-1/2, to radii equal to about 1/4 the maximum radii. No increase in the drag of either body was found.

NACA RM L50I28a

FLIGHT MEASUREMENTS OF BASE PRESSURE ON BODIES OF REVOLUTION WITH AND WITHOUT SIMULATED ROCKET CHAMBERS. Robert F. Peck. November 16, 1950. 21p. diagrs., photos. (NACA RM L50I28a) (Declassified from Confidential, 8/23/54)

Base pressures were measured on fin-stabilized bodies of revolution with and without rocket chambers and with and without a converging afterbody. At Mach numbers between 0.7 and 1.2, the results show that the presence of a "cold" rocket chamber increased the pressure (less suction) over the center portion of the bases. The effects of rocket chambers on pressures near the edge of the bases were not as consistent throughout the Mach number range nor as appreciable at most speeds as were the effects on pressures measured on the center line.

NACA RM L50J02

A PRELIMINARY FLIGHT INVESTIGATION OF THE EFFECTS OF VORTEX GENERATORS ON SEPARATION DUE TO SHOCK. Lindsay J. Lina and Wilmer H. Reed, III. November 30, 1950. 30p. diagrs., photos., tab. (NACA RM L50J02) (Declassified from Confidential, 8/23/54)

A preliminary flight investigation showed that several configurations of vortex generators mounted on the upper surface of a modified wing of an F-51D airplane reduced separation caused by shock.

NACA RM L50J05

A WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF A FULL-SCALE SWEPTBACK PROPELLER AND TWO RELATED STRAIGHT PROPELLERS. Albert J. Evans and George Liner. January 4, 1951. 102p. diagrs., photos., tab. (NACA RM L50J05) (Declassified from Confidential, 8/31/54)

Propeller aerodynamic characteristics are presented and a brief description of the NACA 10-(1.7)(062) -057-27 two-blade swept propeller and two related straight propellers is included. An increase of about 6 percent in the value of helical tip Mach number at which compressibility losses become manifest was realized by the use of sweep. Analysis of the results warns against pseudo gains attained by the use of sweep in propellers at the expense of overall performance.

NACA RM L50J06

INVESTIGATION OF A 42.7° SWEPTBACK WING MODEL TO DETERMINE THE EFFECTS OF TRAILING-EDGE THICKNESS ON THE AILERON HINGE-MOMENT AND FLUTTER CHARACTERISTICS AT TRANSONIC SPEEDS. Robert F. Thompson. December 26, 1950. 42p. diagrs., photos., 2 tabs. (NACA RM L50J06) (Declassified from Confidential, 8/31/54)

A wind-tunnel investigation of a semispan wing-fuselage model having 42.7° of sweepback of the wing leading edge was made through a speed range to a Mach number of 0.60 to 1.175. The 0.20-chord outboard aileron was tested with three trailing-edge to hinge-line thickness ratios ($t = 0$, $t = 0.5$, and $t = 1.0$) to determine the effects on hinge moments and one-degree-of-freedom aileron flutter. Presented are hinge-moment data, hinge-moment parameters, and aileron free-floating characteristics. A comparison of the flutter frequency is made with two previously published empirical analyses.

NACA RM L50J10

TABULATED PRESSURE COEFFICIENTS AND AERODYNAMIC CHARACTERISTICS MEASURED IN FLIGHT ON THE WING OF THE DOUGLAS D-558-I AIRPLANE FOR A 1 g STALL, A SPEED RUN TO A MACH NUMBER OF 0.90, AND A WIND-UP TURN AT A MACH NUMBER OF 0.86. Earl R. Keener and Mary Pierce. December 15, 1950. 40p. diagrs., photos., 5 tabs. (NACA RM L50J10) (Declassified from Confidential, 8/31/54)

Presents tabulated pressure coefficients and aerodynamic characteristics measured in flight on the right wing of the Douglas D-558-I airplane for a 1 g stall, a speed run to a Mach number of 0.90, and a wind-up turn at a Mach number of 0.86.

NACA RM L50J12

DRAG INVESTIGATION OF SOME FIN CONFIGURATIONS FOR BOOSTER ROCKETS AT MACH NUMBERS BETWEEN 0.5 AND 1.4. John C. McFall, Jr. November 21, 1950. 17p. diagrs., photos., tab. (NACA RM L50J12) (Declassified from Confidential, 8/31/54)

This paper presents the results of an investigation using rocket-propelled free-flight models to furnish drag data for booster drag estimates and to determine the drag of various booster fin configurations. Model booster fins of a type extensively used by the NACA were flown through a Mach number range of 0.5 to 1.4. Two booster plan forms were investigated: one with aspect ratio 2.04, taper ratio 0.37, and having various tie-rod bracing and the other, a cantilever design, with aspect ratio 3.20 and taper ratio 0.32.

NACA RM L50J17

SKIN-TEMPERATURE TELEMETER FOR DETERMINING BOUNDARY-LAYER HEAT-TRANSFER COEFFICIENTS. Clifford L. Fricke and Francis B. Smith. March 15, 1951. 22p. diagrs. (NACA RM L50J17) (Declassified from Confidential, 8/31/54)

A method of experimentally determining boundary-layer heat-transfer coefficients by telemetering the skin temperatures of supersonic rockets is given. A platinum resistance wire temperature sensing element developed to indicate accurately the rapidly changing skin temperature is described and the overall accuracy of the instrumentation is discussed.

NACA RM L50J18

INVESTIGATION AT SUPERSONIC SPEEDS OF SOME OF THE FACTORS AFFECTING THE FLOW OVER A RECTANGULAR WING WITH SYMMETRICAL CIRCULAR-ARC SECTION AND 30-PERCENT-CHORD TRAILING-EDGE FLAP. K. R. Czarnecki and James N. Mueller. January 2, 1951. 111p. diagrs., photos. (NACA RM L50J18) (Declassified from Confidential, 8/31/54)

The results of an investigation at supersonic speeds (M = 1.62, 1.93, and 2.40) of some of the factors affecting the flow over a rectangular wing with a symmetrical circular-arc section and a 30-percent-chord trailing-edge flap are presented. The factors included are Mach number, wing thickness, effect of fixing transition, flap-gap leakage, model asymmetry, and surface condition.

NACA RM L50J19

EFFECTS OF SWEEP ON THE DAMPING-IN-ROLL CHARACTERISTICS OF THREE SWEPTBACK WINGS HAVING AN ASPECT RATIO OF 4 AT TRANSONIC SPEEDS. Vernard E. Lockwood. December 14, 1950. 23p. diagrs. (NACA RM L50J19) (Declassified from Confidential, 8/31/54)

The damping-in-roll characteristics of three wings of aspect ratio 4 and taper ratio 0.6 with sweep angles of 0°, 35°, and 45° at the quarter-chord line and an NACA 65A006 airfoil section have been determined through the Mach number range from 0.6 to 1.15 and an angle-of-attack range from 0° to approximately 7° in the Langley 7- by 10-foot-tunnel transonic bump by the twisted-wing method. Comparisons are included with the results obtained at subsonic Mach numbers by the free-roll method on a series of similar wings.

NACA RM L50J20

LOW-SPEED INVESTIGATION OF THE EFFECT OF SEVERAL FLAP AND SPOILER AILERONS ON THE LATERAL CHARACTERISTICS OF A 47.5° SWEPTBACK-WING - FUSELAGE COMBINATION AT A REYNOLDS NUMBER OF 4.4×10^6. Jerome Pasamanick and Thomas B. Sellers. December 8, 1950. 57p. diagrs., photo. (NACA RM L50J20) (Declassified from Confidential, 8/31/54)

Presents results of an investigation in the Langley full-scale tunnel of various plain spoiler and flap-type ailerons on a wing-fuselage combination. The wing leading-edge sweep was 47.5°, the aspect ratio was 3.4, the taper ratio was 0.51, and the airfoil sections were NACA 64_1A112. The data include the effects of aileron span, location, and trailing-edge thickness and of spoiler span, location, and projection on the longitudinal and lateral characteristics at zero yaw for a range of angle of attack at a Reynolds number of 4.4×10^6.

NACA RM L50J30

FLIGHT INVESTIGATION OF THE EFFECT OF SIDESLIP ON THE PRESSURE AT THE STATIC ORIFICES OF THE BOEING B-29 AIRPLANE. Robert G. Chilton and B. Porter Brown. April 11, 1951. 12p. diagrs. (NACA RM L50J30) (Declassified from Confidential, 8/31/54)

The effect of sideslip on the measurement of static pressure obtained from orifices located on each side of the fuselage near the nose of an airplane is shown by measurements taken in steady and oscillatory sideslips. The result is discussed with respect to its effect on the indications of change and rate of change of altitude of an airplane on a bombing run.

NACA RM L50K01a

EFFECTS ON THE SNAKING OSCILLATION OF THE BELL X-1 AIRPLANE OF A TRAILING-EDGE BULB ON THE RUDDER. Hubert M. Drake and Harry P. Clagett. January 16, 1951. 14p. diagrs., photo. (NACA RM L50K01a) (Declassified from Confidential, 8/31/54)

It was found that a rudder trailing-edge bulb did not appreciably affect the snaking oscillation over the Mach number range from 0.75 to 1.0.

NACA RM L50K09

ESTIMATED DECELERATION OF AIRPLANE NOSE SECTION JETTISONED AT VARIOUS ALTITUDES AND AIRSPEEDS. Stanley H. Scher. January 8, 1951. 39p. diagrs. (NACA RM L50K09) (Declassified from Confidential, 8/31/54)

An analytical investigation has been made of the deceleration of typical proposed airplane jettisonable nose sections after being jettisoned at Mach numbers ranging from 0.85 to 3.0 and at altitudes ranging from sea level to 120,000 feet.

NACA RM L50K10

THE EFFECT OF MASS DISTRIBUTION ON THE LOW-SPEED DYNAMIC LATERAL STABILITY AND CONTROL CHARACTERISTICS OF A MODEL WITH A 60° TRIANGULAR WING. Joseph L. Johnson. March 9, 1951. 23p. diagrs., 2 tabs. (NACA RM L50K10) (Declassified from Confidential, 8/31/54)

Results of an investigation to determine the effect of mass distribution on the dynamic lateral stability and control characteristics of a model with a 60° triangular wing are presented. The moments of inertia in roll and yaw were increased to correspond to those of a triangular-wing fighter airplane with wing tanks. Flight tests and calculations were made for five different loading conditions.

NACA RM L50K20

THE USE OF SUCTION TO PREVENT SHOCK-INDUCED SEPARATION IN A NOZZLE. James R. Sterrett, Robert W. Dunning and Maurice J. Brevoort. January 30, 1951. 64p. diagrs., photos., 2 tabs. (NACA RM L50K20) (Declassified from Confidential, 8/31/54)

An investigation was made of the use of suction to prevent shock-induced flow separation in a nozzle formed by a 7.5-percent-thick bump on the wall of a channel. Various transverse and longitudinal suction-slot arrangements and suction through porous surfaces were tested. All these devices were effective in preventing separation, and certain suction-slot arrangements reduced the total power loss, including the power lost in the suction process.

NACA RM L50K27

AN EXPERIMENTAL STUDY AT MODERATE AND HIGH SUBSONIC SPEEDS OF THE FLOW OVER WINGS WITH 30° AND 45° OF SWEEPBACK IN CONJUNCTION WITH A FUSELAGE. Richard T. Whitcomb. June 15, 1951. 56p. diagrs., photos. (NACA RM L50K27) (Declassified from Confidential, 8/31/54)

A relatively extensive study is presented of the pressure distributions, wake surveys, and tuft patterns obtained at Mach numbers to 0.96 for tapered wings with 30° and 45° of sweepback in conjunction with a fuselage.

NACA RM L50K28

AN EXPERIMENTAL STUDY OF MODERATE AND HIGH SUBSONIC SPEEDS OF THE FLOW OVER WINGS WITH 30° AND 45° OF SWEEPFORWARD IN CONJUNCTION WITH A FUSELAGE. Richard T. Whitcomb. June 15, 1951. 47p. diagrs., photo. (NACA RM L50K28) (Declassified from Confidential, 8/31/54)

A relatively extensive study is presented of the pressure distributions and wake measurements obtained at Mach numbers to 0.96 for tapered wings with 30° and 45° of sweepforward, in conjunction with a fuselage.

NACA RM L50L01

AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A 60° DELTA WING EQUIPPED WITH A TRIANGULAR PLAN-FORM CONTROL HAVING A SKEWED HINGE AXIS AND AN OVERHANG BALANCE. TRANSONIC-BUMP METHOD. Harleth G. Wiley. February 6, 1951. 31p. diagrs. (NACA RM L50L01) (Declassified from Confidential, 8/31/54)

This paper presents the aerodynamic characteristics of a 60° delta wing of aspect ratio 2.31, taper ratio 0, and an NACA 65-006 airfoil section, which was equipped with an aerodynamically balanced triangular control mounted on a skewed hinge axis. Lift, drag, pitching moment, rolling moment, and hinge moment were obtained at various angles of control deflection and angles of attack through a Mach number range of 0.6 to 1.18.

NACA RM L50L04

EFFECTS OF SEVERAL ARRANGEMENTS OF RECTANGULAR VORTEX GENERATORS ON THE STATIC-PRESSURE RISE THROUGH A SHORT 2:1 DIFFUSER. E. Floyd Valentine and Raymond B. Carroll. February 20, 1951. 35p. diagrs., photos. (NACA RM L50L04) (Declassified from Confidential, 8/31/54)

Several arrangements of simple rectangular noncambered vortex generators were investigated in a 2:1 area-ratio diffuser of length equal to the inlet diameter and having an initial boundary-layer thickness of 5 percent of the inlet diameter. Some arrangements actually reduced the diffuser static-pressure rise. The effect of one of the better vortex-generator arrangements was to increase the diffuser effectiveness by 30 percent making it equal to that of a diffuser of twice the length.

NACA RM L50L04a

PRESSURE DISTRIBUTIONS OVER A RETRACTED LEADING-EDGE SLAT ON A 40° SWEPTBACK WING AT MACH NUMBERS UP TO 0.9. Jones F. Cahill and Gale C. Oberndorfer. January 26, 1951. 36p. diagrs. (NACA RM L50L04a) (Declassified from Confidential, 8/31/54)

Pressure distributions over a retracted leading-edge slat on a 40° sweptback wing are presented for a series of angles of attack up to maximum lift at Mach numbers of 0.1, 0.4, 0.6, 0.7, 0.8, 0.85, and 0.9. These data were obtained in the Langley low-turbulence pressure tunnel at a constant Reynolds number of approximately 3×10^6. The Reynolds number was maintained approximately constant through the Mach number range by varying the stagnation pressure.

NACA RM L50L07

AN EXPERIMENTAL STUDY OF MODERATE AND HIGH SUBSONIC SPEEDS OF THE FLOW OVER AN UNSWEPT WING IN CONJUNCTION WITH A FUSELAGE. Richard T. Whitcomb. June 18, 1951. 35p. diagrs., photos. (NACA RM L50L07) (Declassified from Confidential, 8/31/54)

A relatively extensive study is presented of the pressure distributions, wake measurements, and tuft patterns obtained for an unswept, high-aspect-ratio, tapered wing, in conjunction with a fuselage, at Mach numbers up to 0.925.

NACA RM L50L12a

TABULATED PRESSURE COEFFICIENTS AND AERODYNAMIC CHARACTERISTICS MEASURED IN FLIGHT ON THE WING OF THE DOUGLAS D-558-I AIRPLANE THROUGHOUT THE NORMAL-FORCE-COEFFICIENT RANGE AT MACH NUMBERS OF 0.67, 0.74, 0.78, AND 0.82. Earl R. Keener, James R. Peele and Julia B. Woodbridge. January 29, 1951. 37p. diagrs., photos., 6 tabs. (NACA RM L50L12a) (Declassified from Confidential, 8/31/54)

Tabulated pressure coefficients and aerodynamic characteristics measured in flight on the right wing of the Douglas D-558-I airplane throughout the normal-force-coefficient range at Mach numbers of 0.67, 0.74, 0.78, and 0.82 are presented.

NACA RM L50L18

FLIGHT DETERMINATION OF THE DRAG AND PRESSURE RECOVERY OF AN NACA 1-40-250 NOSE INLET AT MACH NUMBERS FROM 0.9 TO 1.8. R. I. Sears and C. F. Merlet. February 28, 1951. 32p. diagrs., photos., 2 tabs. (NACA RM L50L18) (Declassified from Confidential, 8/31/54)

External-drag and pressure-recovery data are presented for the NACA 1-40-250 nose inlet. The tests were made using rocket-propelled models in free flight at Mach numbers from 0.9 to 1.8. The Reynolds number based on body diameter varied from 4 to 10×10^6.

NACA RM L50L28

ERROR IN AIRSPEED MEASUREMENT DUE TO STATIC-PRESSURE FIELD AHEAD OF THE WING TIP OF A SWEPT-WING AIRPLANE MODEL AT TRANSONIC SPEEDS. Edward C. B. Danforth and Thomas C. O'Bryan. March 1, 1951. 16p. diagrs., photo. (NACA RM L50L28) (Declassified from Confidential, 8/31/54)

Contains measurements of static pressure taken at a distance of 1 tip chord ahead of the wing tip of a model of a swept-wing fighter airplane for the condition of near zero lift. The measurements made by means of the NACA wing-flow method cover a range of Mach numbers from 0.7 to 1.08. The influence of the complete airplane configuration on the static pressure is shown, together with the influences of the wing and fuselage taken separately. Comparisons with the linear theory are made where possible.

NACA RM L51A16

A COMPARISON OF TWO TECHNIQUES UTILIZING ROCKET-PROPELLED VEHICLES FOR THE DETERMINATION OF THE DAMPING-IN-ROLL DERIVATIVE. David G. Stone and Carl A. Sandahl. May 3, 1951. 17p. diagrs., photos. (NACA RM L51A16) (Declassified from Confidential, 8/31/54)

Rocket-powered flight investigations have been conducted for the purposes of comparing damping-in-roll derivatives as obtained from the torque-nozzle technique and the sting-mount technique. The agreement in damping-in-roll values obtained by the two techniques was good and showed the transonic rolling behavior of wings to be more affected by wing-dropping characteristics than by damping in roll.

NACA RM L51A17

APPLICATION OF THEODORSEN'S PROPELLER THEORY TO THE CALCULATION OF THE PERFORMANCE OF DUAL-ROTATING PROPELLERS. Jean Gilman, Jr. March 15, 1951. 31p. diagrs. (NACA RM L51A17) (Declassified from Confidential, 8/31/54)

Theodorsen's propeller theory is used to calculate the performance of dual-rotating propellers having nonideal load distributions. The ratio of the spinner radius to the propeller radius is shown to have a significant effect in evaluating the mass coefficient used in making calculations for either performance or design work. Sample performance calculations are made and the results are compared with experimental results for flight Mach numbers varying from 0.53 to 0.90.

NACA RM L51A18

CORRELATION OF SUPERSONIC CONVECTIVE HEAT-TRANSFER COEFFICIENTS FROM MEASUREMENTS OF THE SKIN TEMPERATURE OF A PARABOLIC BODY OF REVOLUTION (NACA RM-10). Leo T. Chauvin and Carlos A. deMoraes. March 7, 1951. 39p. diagrs., photo. 2 tabs. (NACA RM L51A18) (Declassified from Confidential, 8/31/54)

Free-flight tests at supersonic speeds have been made to determine the local convective heat-transfer coefficients, evaluated from measured skin temperatures along the body of a rocket-propelled fin-stabilized parabolic body of revolution. The Mach number range covered was 1.02 to 2.48 and the Reynolds number range was 3.18×10^6 to 163.85×10^6. The experimental values are compared with the results obtained from the V-2 research missile and also with several equations for heat transfer in a turbulent boundary layer.

NACA RM L51A19

THE TORSIONAL DEFLECTIONS OF SEVERAL PROPELLERS UNDER OPERATING CONDITIONS. W. H. Gray and A. E. Allis. June 1951. 56p. diagrs., photos., tab. (NACA RM L51A19) (Declassified from Confidential, 8/31/54)

Presents measured and computed torsional deflections of the family of constant-chord solid aluminum-alloy propeller blades used in a concurrent investigation of blade-section pressure distributions. The deflections were not negligible and varied with blade design and operating condition. It was concluded that blade torsional deflection may be computed with sufficient accuracy and should be considered in the design of thin propeller blades.

NACA RM L51A23

FLIGHT DETERMINATION OF THE EFFECTS OF WING VORTEX GENERATORS ON THE AERODYNAMIC CHARACTERISTICS OF THE DOUGLAS D-558-I AIRPLANE. De E. Beeler, Donald R. Bellman and John H. Griffith. August 14, 1951. 23p. diagrs., photos., tab. (NACA RM L51A23) (Declassified from Confidential, 8/31/54)

Tests were made to determine the effects of wing vortex generators on the handling and buffeting characteristics of the Douglas D-558-I airplane. Measurements of the chordwise pressure distribution over one section of the wing, the total-head losses in a portion of the wing wake, the total airplane drag, and the buffeting and handling characteristics were made with the basic configuration and with vortex generators of an arbitrary size, shape, and location installed on the wing.

NACA RM L51B12

AVERAGE SKIN-FRICTION COEFFICIENTS FROM BOUNDARY-LAYER MEASUREMENTS IN FLIGHT ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT SUPERSONIC SPEEDS AND AT LARGE REYNOLDS NUMBERS. Charles B. Rumsey and J. Dan Loposer. March 7, 1951. 33p. diagrs., photo. (NACA RM L51B12) (Declassified from Confidential, 8/31/54)

Boundary-layer measurements were made at two stations on a rocket-powered, fin-stabilized, parabolic body of revolution of fineness ratio 12.2. Skin-friction coefficients were determined over a Mach number range from 1.5 to 3.4 and over the Reynolds number range, based on body length to the measurement station, from 42×10^6 to 160×10^6. Theoretical turbulent skin-friction coefficients for a flat plate, with heat transfer, are also shown.

NACA RM L51B13

THE EFFECT OF END PLATES, END STRUTS, AND DEPTH OF SUBMERGENCE ON THE CHARACTERISTICS OF A HYDROFOIL. Kenneth L. Wadlin, Rudolph E. Fontana and Charles L. Shuford, Jr. April 12, 1951. 84p. diagrs., photos. (NACA RM L51B13) (Declassified from Confidential, 8/31/54)

An investigation was made in Langley tank No. 2, at subcavitation speeds, of the effect of end plates and end-mounted struts. Only small improvements might be expected in the maximum lift-drag ratios by the addition of end plates. End struts reduced the lift-drag ratio attainable with a single strut. The effect of end plates and end struts on effective aspect ratio was in good agreement with theory. An approximate theoretical solution of the effect of depth on the lift of a hydrofoil was developed.

NACA RM L51B28

NOTE ON FLUTTER OF A 60° DELTA WING ENCOUNTERED AT LOW-SUPERSONIC SPEEDS DURING THE FLIGHT OF A ROCKET-PROPELLED MODEL. William T. Lauten, Jr. and Grady L. Mitcham. May 14, 1951. 21p. diagrs., photos., 5 tabs. (NACA RM L51B28) (Declassified from Confidential, 8/31/54)

Results of the flight test of a rocket-powered model of a delta-wing (60° sweepback) body configuration indicated a wing flutter at a Mach number of 1.11 and a subsequent structural failure of a Mach number of 0.99. Sections of the flight time history and the ground-test results of a duplicate wing for natural frequencies of vibration, the structural influence coefficients, and the mass, moment of inertia, and center of gravity of streamwise strips of the wing are presented.

NACA RM L51C07

EFFECT OF A DEFLECTABLE WING-TIP CONTROL ON THE LOW-SPEED LATERAL AND LONGITUDINAL CHARACTERISTICS OF A LARGE-SCALE WING WITH THE LEADING EDGE SWEPT BACK 47.5°. Roy H. Lange and Marvin P. Fink. April 26, 1951. 41p. diagrs., photo., 2 tabs. (NACA RM L51C07) (Declassified from Confidential, 8/31/54)

Results are presented of an investigation in the Langley full-scale tunnel of the effect of a 20-percent-semispan deflectable wing-tip control on the low-speed lateral and longitudinal characteristics of a wing with the leading edge swept back 47.5° and circular-arc-airfoil sections. The basic wing configurations, the wing with drooped-nose flaps deflected 40°, and the wing with drooped-nose and semispan plain flaps deflected 40° were investigated throughout. All the data are presented for a Reynolds number of 4.3×10^6 and a Mach number of 0.07.

NACA RM L51C26

AERODYNAMIC CHARACTERISTICS OF TAPERED WINGS HAVING ASPECT RATIOS OF 4, 6, AND 8, QUARTER-CHORD LINES SWEPT BACK 45°, AND NACA 631A012 AIRFOIL SECTIONS. TRANSONIC-BUMP METHOD. Edward C. Polhamus and Thomas J. King, Jr. June 13, 1951. 23p. diagrs., photos., 2 tabs. (NACA RM L51C26) (Declassified from Confidential, 8/31/54)

This paper presents the results of an investigation by the transonic-bump method of wings of aspect ratios 8, 6, and 4 with the quarter-chord lines swept back 45°, and having NACA 631A012 airfoil sections, parallel to the plane of symmetry. Lift, drag, pitching-moment, and root bending-moment characteristics are presented for the Mach number range from 0.70 to 1.15.

NACA RM L51D18

FLIGHT INVESTIGATION OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF THE DOUGLAS D-558-I AIRPLANE (BUAERO NO 37972) AT MACH NUMBERS UP TO 0.89. Melvin Sadoff, William S. Roden and John M. Eggleston. June 1951. 26p. diagrs., photos., tab. (NACA RM L51D18) (Declassified from Confidential, 8/31/54)

Results and analysis pertaining to the longitudinal stability and control characteristics of the Douglas D-558-I airplane (BuAero No. 37972) are presented. The results indicated that large and rapid changes in elevator deflection and force were required for balance above a Mach number of 0.84. Analysis indicated that a major part of these changes was due to a loss in elevator effectiveness. A large increase in the apparent stick-fixed stability parameter $d\delta_e/dC_N$ was also noted due to a loss in elevator effectiveness combined with an increase in airplane stability.

NACA RM L51D19

EFFECTS OF SPANWISE THICKNESS VARIATION ON THE AERODYNAMIC CHARACTERISTICS OF 35° AND 45° SWEPTBACK WINGS OF ASPECT RATIO 6. TRANSONIC-BUMP METHOD. William D. Morrison, Jr. and Paul G. Fournier. July 1951. 38p. diagrs., photo. (NACA RM L51D19) (Declassified from Confidential, 8/31/54)

The effects of taper-in-thickness on the aerodynamic characteristics of wings having 35° and 45° of sweepback, aspect ratio 6, and taper ratio 0.6 have been determined by the transonic-bump technique over a Mach number range from 0.6 to 1.14. The results of this investigation are compared with those obtained from wings of the same plan form but of various constant section thickness ratios. Theoretical subsonic and low supersonic calculations of lift-curve slope, aerodynamic center, and lateral center-of-pressure location were determined.

NACA RM L51D23

THEORETICAL INVESTIGATION OF AN AUTOMATIC CONTROL SYSTEM WITH PRIMARY SENSITIVITY TO NORMAL ACCELERATIONS AS USED TO CONTROL A SUPERSONIC CANARD MISSILE CONFIGURATION. Ernest C. Seaberg and Earl F. Smith. July 1951. 48p. diagrs., photo., 3 tabs. (NACA RM L51D23) (Declassified from Confidential, 8/31/54)

An analysis has been made to determine the possibilities of using an autopilot primarily sensitive to linear accelerations for longitudinal control of a specific supersonic canard airframe. Essentially, the control system combines the use of a linear accelerometer and an integrating servomotor to obtain desired normal accelerations of the missile. The analysis is based largely on comparisons of normal acceleration transient responses obtained for various conditions of Mach number, altitude, static margin, and rate-of-pitch feedback. Because the acceleration control system has no directional space reference of its own, it is believed that its primary usefulness is in conjunction with a homing seeker or with a guidance system which will provide a directional space reference.

NACA RM L51D24

PRESSURE-DISTRIBUTION MEASUREMENTS OVER A 45° SWEPTBACK WING AT TRANSONIC SPEEDS BY THE NACA WING-FLOW METHOD. Edward C. B. Danforth and Thomas C. O'Bryan. June 1951. 42p. diagrs., photos. (NACA RM L51D24) (Declassified from Confidential, 8/31/54)

Pressure distributions have been obtained over the chord of an untapered, 45° sweptback wing model of 3.5 aspect ratio with 2-inch-chord NACA 65-210 airfoil sections normal to the leading edge at four stations along the span. The measurements, made by the NACA wing-flow method, covered Mach numbers from 0.7 to 1.1 and angles of attack from -1° to 4° at a nominal Reynolds number of 0.6×10^6 based on the chord. Comparisons are made with force tests and theory where possible.

NACA RM L51D24a

WING-FLOW INVESTIGATION OF THE CHARACTERISTICS OF SEVEN UNSWEPT, UNTAPERED AIRFOILS OF ASPECT RATIO 8.0. Harold L. Crane and James J. Adams. June 13, 1951. 54p. diagrs., photo. (NACA RM L51D24a) (Declassified from Confidential, 8/31/54)

Measurements were made of normal force, chord force, and pitching moment at angles of attack from -6° to 14° and Mach numbers of 0.65 to 1.08, for seven airfoil sections. The sections included were NACA 65-010, 65-210, 836D110, 847B110, a 10-percent-thick airfoil with 3-to-1 elliptical nose faired into a straight-sided afterbody, an airfoil having the same thickness distribution and a reflex-camber line obtained by subtracting an NACA 240 from an NACA 420 mean line, and an airfoil having the thickness distribution of the NACA 65-010 and the reflex-camber line.

NACA RM E54G07

INVESTIGATION OF NOISE FIELD AND VELOCITY PROFILES OF AN AFTERBURNING ENGINE. Warren J. North, Edmund E. Callaghan and Chester D. Lanzo. September 1954. 23p. diagrs., photos. (NACA RM E54G07)

Sound pressure levels and jet velocity profiles are presented for an engine-afterburner combination over a range of afterburner fuel-air ratios. At high fuel-air ratios, a severe low-frequency resonance producing high noise levels was encountered. A current fighter aircraft with a different afterburner configuration yielded considerably lower sound pressure levels and resonance-free operation, indicating the importance of acoustic considerations in afterburning designs.

NACA RM E54G22a

RECOVERY CORRECTIONS FOR BUTT-WELDED, STRAIGHT-WIRE THERMOCOUPLES IN HIGH-VELOCITY, HIGH-TEMPERATURE GAS STREAMS. Frederick S. Simmons. September 1954. 19p. diagrs. (NACA RM E54G22a)

Experimental measurements show that a reasonable correlation among recovery corrections at various pressures and temperatures for butt-welded straight-wire thermocouples is given by an empirical equation in which the correction is seen to be proportional to the fifth root of the pressure and inversely proportional to the fourth root of the temperature. Resultant probable errors in temperature measurements are presented and discussed.

NACA TN 3151

EXACT SOLUTIONS OF LAMINAR-BOUNDARY-LAYER EQUATIONS WITH CONSTANT PROPERTY VALUES FOR POROUS WALL WITH VARIABLE TEMPERATURE. Patrick L. Donoughe and John N. B. Livingood. September 1954. 42p. diagrs., 2 tabs. (NACA TN 3151)

Solutions were computed for a Prandtl number of 0.7 and a range of cooling-air flows, and pressure and wall temperature gradients. For each case, boundary layer thicknesses and heat-transfer and friction coefficients were also computed and tabulated. Steeper temperature profiles for a given coolant flow were obtained by increased wall temperature gradients. Wall temperature gradients for zero boundary-layer tamperature gradients at the wall were increased by increased pressure gradient and decreased by increased coolant flow.

NACA TN 3200

STRESS ANALYSIS OF CIRCULAR SEMIMONOCOQUE CYLINDERS WITH CUTOUTS BY A PERTURBATION LOAD TECHNIQUE. Harvey G. McComb, Jr. September 1954. 37p. diagrs., 3 tabs. (NACA TN 3200)

A method is presented for analyzing the stresses about a cutout in a circular cylinder of semimonocoque construction. The method involves the use of so-called perturbation solutions which are superposed on the stress distribution that would exist in the structure with no cutout in such a way as to give the effects of a cutout. The method can be used for any loading case for which the structure without the cutout can be analyzed and is sufficiently versatile to account for stringer and shear reinforcement about the cutout.

NACA TN 3213

TRANSONIC FLOW PAST CONE CYLINDERS. George E. Solomon, California Institute of Technology. September 1954. 56p. diagrs., photos. (NACA TN 3213)

Experimental results are presented for transonic flow past cone-cylinder, axially symmetric bodies. The drag coefficient and surface Mach number are studied as the free-stream Mach number is varied and, wherever possible, the experimental results are compared with theoretical predictions. Interferometric results for several typical flow configurations are shown and an example of shock-free supersonic-to-subsonic compression is experimentally demonstrated. The theoretical problem of transonic flow past finite cones is discussed briefly and an approximate solution of the axially symmetric transonic equations, valid for a semi-infinite cone, is presented.

NACA TN 3227

APPLICATION OF TWO-DIMENSIONAL VORTEX THEORY TO THE PREDICTION OF FLOW FIELDS BEHIND WINGS OF WING-BODY COMBINATIONS AT SUBSONIC AND SUPERSONIC SPEEDS. Arthur Wm. Rogers. September 1954. (ii), 91p. diagrs., photo., 3 tabs. (NACA TN 3227)

A theoretical method is evaluated for predicting flow fields behind wings of wing-body combinations at supersonic speeds and slender configurations at subsonic speeds. The method was applied to the calculation of downwash at tail locations behind wings of triangular-wing and cylindrical-body combinations at M = 2.0, to illustrate effects of aspect ratio, angle of attack and incidence, ratio of body radius to wing semispan, and angle of bank on the vortex wake.

NACA TN 3243

THEORETICAL ANALYSIS OF AN AIRPLANE ACCELERATION RESTRICTOR CONTROLLED BY NORMAL ACCELERATION, PITCHING ACCELERATION, AND PITCHING VELOCITY. Christopher C. Kraft, Jr. September 1954. 42p. diagrs., 3 tabs. (NACA TN 3243)

An acceleration restrictor which limits the elevator motion has been analyzed. The system has been assumed to be sensitive to two different control signals. One signal is proportional to normal and pitching acceleration and the other is a function of normal and pitching acceleration and pitching velocity. Several values of time lag in the device used to stop the elevator motion have been studied for two center-of-gravity positions and for forward speeds up to 1,000 feet per second.

NACA TN 3246

AN EXPERIMENTAL INVESTIGATION OF WHEEL SPIN-UP DRAG LOADS. Benjamin Milwitzky, Dean C. Lindquist and Dexter M. Potter. September 1954. 18p. diagrs. (NACA TN 3246. Formerly RM L53E06b)

This paper presents some recently obtained information on landing-gear applied drag loads and on the nature of the wheel spin-up phenomenon in landing, based on a program of tests under controlled conditions in the Langley impact basin. In particular, a study has been made of the nature and variation of the coefficient of friction between the tire and the runway during the spin-up process. Also, comparisons have been made of the various results obtained in forward-speed impacts, forward-speed impacts with reverse wheel rotation, spin-up drop tests, and forward-speed impacts with wheel prerotation.

NACA TN 3262

STARTING AND OPERATING LIMITS OF TWO SUPERSONIC WIND TUNNELS UTILIZING AUXILIARY AIR INJECTION DOWNSTREAM OF THE TEST SECTION. Henry R. Hunczak and Morris D. Rousso. September 1954. 28p. diagrs., photo. (NACA TN 3262)

Data are presented for tunnels operating at Mach numbers 3.85, 3.05, and 2.87 over a range of injector-to-tunnel mass-flow ratios of 0.5 to 1.35. At Mach number 3.85, the starting pressure ratio of 9.8 without injectors but with a fixed second throat was reduced to 4.68 with injectors operating at an injector-to-tunnel mass-flow ratio of 1.27. The running pressure ratio was lowered from 8.3 to 4.5. Corresponding reductions at Mach number 3.05 were from 4.5 to 2.71 for starting and from 4.5 to 2.37 for running at a mass-flow ratio of 0.9.

NACA TN 3285

SECTION CHARACTERISTICS OF AN NACA 0006 AIRFOIL WITH AREA SUCTION NEAR THE LEADING EDGE. James A. Weiberg and Robert E. Dannenberg. September 1954. 47p. diagrs., photos., 3 tabs. (NACA TN 3285)

Results are presented of an investigation of a two-dimensional NACA 0006 airfoil with area suction near the leading edge. The maximum lift of the wing without suction was increased 43 percent for a section flow coefficient of 0.0010 at a free-stream velocity of 162 feet per second.

NACA TN 3287

HEAT TRANSFER FROM A HEMISPHERE-CYLINDER EQUIPPED WITH FLOW-SEPARATION SPIKES. Jackson R. Stalder and Helmer V. Nielsen. September 1954. 29p. diagrs., photos. (NACA TN 3287)

Average heat-transfer, temperature-recovery, and pressure-distribution measurements were obtained over the hemispherical nose of a body of revolution both with and without flow-separation spikes. The tests, conducted in a range of Reynolds numbers from 1.55 to 9.85 x 10^5 and from Mach number 0.12 to 5.04, indicated that in supersonic flow the addition of spikes approximately doubles the rate of heat transfer, regardless of spike length.

NACA TN 3300

INVESTIGATION OF LIFT, DRAG, AND PITCHING MOMENT OF A 60° DELTA-WING—BODY COMBINATION (AGARD CALIBRATION MODEL B) IN THE LANGLEY 9-INCH SUPERSONIC TUNNEL. August F. Bromm, Jr. September 1954. 18p. diagrs., photos. (NACA TN 3300)

Results are presented from tests of the AGARD Calibration Model B in the Langley 9-inch supersonic tunnel. Measurements were made of the lift, drag, and pitching moment at Mach numbers of 1.62, 1.94, and 2.41 and at a Reynolds number, based on body length, of approximately 3.0 x 10^6. The zero-lift drag data compared favorably with available data and were in the proper sequence for the effects of Reynolds number.

THE REFLECTION AND TRANSMISSION OF PRESSURE DISTURBANCES AT AREA CHANGES IN INFINITE DUCTS. M. V. Nesbitt. February 1954. 103p. diagrs., tab. (NGTE Memo. M. 198)

In most problems involving the propagation of pressure disturbances, reflection, and transmission of the disturbance at area changes must be considered. In this paper data are presented describing the reflection and transmission of pressure disturbances at abrupt area changes inside infinite ducts and at the ends of semi-infinite ducts. The presentation is such that only an initial flow condition, the ratio of the downstream area to the upstream area, the pulse size and its direction of travel need be defined to obtain the magnitude of the reflected and transmitted pulses. Although the results are expressed in terms of the sonic velocities in the various flow regions, they may be readily converted to terms of pressure or velocity. The data refers only to Mach numbers less than 1.

A HOT-WIRE ANEMOMETER FOR THE MEASUREMENT OF SMALL AIRFLOWS. P. A. Stickles and T. R. H. Sizer. March 1954. 16p. diagrs., photos. (RAE Tech. Note EL. 50)

The principle underlying the operation of the hot-wire anemometer and its field of application in the measurement of small air flow are described. Full electrical and constructional details of the instrument are given together with details of a cone-valve for controlling the back-pressure and a low-pressure chamber for simulating high altitude conditions. The sources of error are discussed and an indication is given of the limits of accuracy to be expected.

APPROXIMATE THEORETICAL CALCULATIONS OF THE EFFECT OF CYLINDRICAL TAILPIPES ON THE THRUST OF A ROCKET MOTOR. D. M. Clemmow. March 1954. 57p. diagrs., 16 tabs. (RAE RPD 18)

Assuming one-dimensional flow (free from oblique shocks) calculations have been made of the effect of nonconducting cylindrical tailpipes on the thrust delivered by rocket motors. Both supersonic and subsonic pipes of a range of lengths and diameters have been examined for a number of different chamber pressures, and for each case optimum area expansion ratios for motors with pipes have been determined. With supersonic pipes the thrust loss increases to a maximum value (of nearly 20 percent for the worst case investigated) which occurs when the pipe is long enough for the flow to become sonic at its downstream end. With subsonic pipes the existence of irreversible flow upstream of the nozzle throat necessitates separate examination of different cases.

STATIC AND DYNAMIC RESPONSE OF A DESIGN OF DIFFERENTIAL PRESSURE YAWMETER AT SUPERSONIC SPEEDS. L. J. Beecham and S. J. Collins. February 1954. 56p. diagrs., photos. (RAE GW 19)

Static calibration curves are provided for incidences up to 30° at speeds from M = 1.3 to 1.9, and the instrument is shown to resolve accurately when rolled out of the free stream incidence plane. Relations are developed from which a close approximation to the Mach number, incidence and roll angle may be obtained, without recourse to calibration curves, in terms of the differential pressures across each pair of holes and the pitot pressure measured at an axial hole; the free stream static pressure requires to be determined independently. Dynamic behavior of the instrument and associated pressure pick-ups is examined, and a design developed for which the acoustic natural frequency is high compared with that likely to be encountered in flight.

THE DESIGN AND TESTING OF A FULL SCALE VORTEX COMBUSTION CHAMBER FOR RESIDUAL OIL BURNING. A. P. Johnstone. March 1954. 65p. diagrs., photos., 5 tabs. (NGTE Memo. M. 203)

This memorandum describes the design, development, and performance of a large vortex chamber burning 6,000 seconds residual fuel oil. The chamber was designed to pass 38 lb/sec of air at 4 atmospheres and 100 percent overload tests were attempted. The chamber was fully cooled by dilution air for a total loss of 2.0 lb/sq in. at 4 atmospheres. The system had three tangential entries and operated on one, two, or three entries with uniform symmetrical exhaust temperature profiles. Combustion efficiencies were high, 97 to 99 percent, falling off more rapidly below about 50 percent of the design mixture strength.

Ministry of Supply (Gt. Brit.)
AN ANALYSIS OF N. A. C. A. HELICOPTER REPORTS. R. N. Liptrot. May 1954. 61p. diagrs., 5 tabs. (MOS S & TM 7/54)

Theory is compared with flight and model tests, in order to obtain empiric correcting factors which will enable reliable performance estimates to be made for new helicopter designs. A survey of general theory is followed by an analysis of certain American reports. Correcting factors for effective blade drag for tip speed ratio, compressibility and stalling of the retreating blade are derived. A method of calculating the retreating blade tip angle of attack for twisted blades is presented. The work was carried out by the author under Ministry of Supply sponsorship.

Royal Aircraft Establishment (Gt. Brit.)
THE TENSILE PROPERTIES OF D. T. D. 546 AND D. T. D. 687 AFTER HEATING AT ELEVATED TEMPERATURES. May 1954. 5p. diagrs. (RAE Tech. Note Met. 197)

The tensile properties of D. T. D. 546 and D. T. D. 687 after heating at various temperatures up to about 300° C for periods ranging from 5 seconds to 1000 hours have been reviewed and plotted in convenient curves. At temperatures of about 125° C and above, the aluminum-zinc-magnesium alloy D. T. D. 687 loses strength to a very much greater extent than the D. T. D. 546, thus losing the higher strength advantage it possesses at room temperature.

Royal Aircraft Establishment (Gt. Brit.)
TENSILE AND COMPRESSIVE TESTS ON TITANIUM STRIP AT ELEVATED TEMPERATURES. D. C. Hayward. March 1954. 34p. diagrs., photos., 12 tabs. (RAE Tech. Note Met. 194)

The compressive testing of hot rolled commercial purity titanium strip was carried out in a fixture using steel balls to prevent lateral buckling of the test piece. Tests in tension and compression at temperatures ranging from room temperature to 400° C were made to provide data for tangent moduli graphs. Longitudinal and transverse tensile strength values were almost equal but under compression there was marked anisotropy. Strength was well maintained at the higher temperatures. Differences in stiffness were greatest at room temperature but were appreciably reduced at 400° C.

DESIGN AND DEVELOPMENT OF THE R. A. E. DUMMY OF THE STANDARD AIRMAN. G. Lovell. May 1954. 27p. diagrs., photos., 4 tabs. (RAE Tech. Note Mech. Eng. 176)

A dummy of the standard airman has been developed at the R. A. E. for use in dynamic and static tests. It has been designed to the dimensions of the average airman and the limbs and the complete man have approximately the correct weights and centers of gravity. Its all up weight is normally 166 pounds but it can be varied from this figure if desired. The dummy has a basic metal structure, covered with foam rubber and articulated at the joints. While it is normally fitted with a simple canvas suit, it can be dressed in standard aircrew clothing, equipment, and headgear. There are cavities for instruments in the head and in the upper and lower trunks. A box containing three mechanical accelerometers mutually at right angles can be fitted in each of these cavities.

THE STABILITY OF THE RUNGE-KUTTA METHOD OF SOLUTION OF LINEAR DIFFERENTIAL EQUATIONS. R. H. Merson. June 1954. 12p. diagrs. (RAE Tech. Note GW 320)

The solution of a linear differential equation with constant coefficients as given by the Runge-Kutta method is obtained and the stability is studied. It is shown that the Runge-Kutta solution will be stable when the true solution is stable if the interval of integration is less than about 2.8 times the time constant of every subsidence and less than about 2.8 times the reciprocal of the undamped frequency of every oscillatory mode.

Royal Aircraft Establishment (Gt. Brit.)
FLEXIBLE EDGE ATTACHMENTS FOR WINDSCREENS. F. M. Clowes and L. W. Lord. May 1954. 13p. diagrs., 3 tabs. (RAE Tech. Note Chem. 1228)

A flexible edge attachment consisting of glass cloth and polyvinylbutyral has been developed for aircraft windscreens. While the attachment enables the windscreen to be bolted securely to the frame, it will accommodate a difference of thermal expansion between the frame and the windscreen. The joint strength decreases with rise in temperature so that the method is best suited to normal and low temperature conditions.

INDEX OF NACA TECHNICAL PUBLICATIONS, JUNE, 1953 - MAY, 1954. 1954. viii, 212p. (NACA)

There is a classified listing of subject categories; a chronological listing of NACA publications under each subject category; an alphabetical index to the subject categories; and an author index.

NACA Rept. 1135

Errata No. 1 on "EQUATIONS, TABLES, AND CHARTS FOR COMPRESSIBLE FLOW." Ames Research Staff. 1953.

NACA TN 3109

Errata No. 1 on "AN INVESTIGATION OF LAMELLAR STRUCTURES AND MINOR PHASES IN ELEVEN COBALT-BASE ALLOYS BEFORE AND AFTER HEAT TREATMENT." J. W. Weeton and R. A. Signorelli. March 1954.

NACA TN 3118

Errata No. 2 on "DESIGN DATA FOR MULTIPOST-STIFFENED WINGS IN BENDING." Roger A. Anderson, Aldie E. Johnson, Jr. and Thomas W. Wilder, III. January 1954.

UNPUBLISHED PAPERS

N-18639*

ON THE SUITABILITY OF ELECTROLYTICALLY POLISHED SPECIMENS FOR THE METALLOGRAPHIC INVESTIGATION OF ALUMINUM AND ITS ALLOYS. (Über die Eignung elektrolytische polierter Proben für die metallographische Untersuchung von Aluminum und seinen Legierungen). H. Rohrig and W. Schneider. August 1954. 10p. diagr., photos. (Trans. from Aluminum, v. 23, no. 6, June, 1941, p. 281-284)

Known methods for electrolytic polishing of aluminum parts are reviewed and discussed. It is concluded that the applicability of electrolytic polishing methods to the preparation of metallographic specimens in the field of aluminum is comparatively limited.

DECLASSIFIED NACA REPORTS

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM CONFIDENTIAL, 9/10/54

RM A51H20
RM L51I11

NACA RM A50H03

PRELIMINARY FLIGHT INVESTIGATION OF THE WING-DROPPING TENDENCY AND LATERAL-CONTROL CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE AT TRANSONIC MACH NUMBERS. George A. Rathert, Jr., L. Stewart Rolls, Lee Winograd and George E. Cooper. September 11, 1950. 14p. diagrs., photo., tab. (NACA RM A50H03) (Declassified from Confidential, 9/10/54)

Results are presented from a preliminary flight investigation on an F-86A airplane of the lateral-control characteristics and the wing-dropping tendency encountered at high Mach numbers. The wing-dropping tendency was found to result from a combination of three factors: a small initial directional asymmetry, an abrupt increase in positive dihedral effect, and a reduction in the lateral-control effectiveness.

NACA RM A50J09a

PRELIMINARY FLIGHT INVESTIGATION OF THE DYNAMIC LONGITUDINAL-STABILITY CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE. William C. Triplett and Rudolph D. Van Dyke, Jr. December 11, 1950. 26p. diagrs., photo., tab. (NACA RM A50J09a) (Declassified from Confidential, 9/10/54)

Flight tests were conducted on a 35° swept-wing airplane to determine the dynamic longitudinal-stability characteristics. Period and damping of oscillatory responses were measured over a Mach number range of 0.60 to 1.04. Also presented as functions of Mach number are the static stability parameter C_{m_α}, the factor $C_{m_q} + C_{m_{\dot{\alpha}}}$, and the number of cycles required for the oscillation to damp to 1/10 amplitude. Sharp variations in damping were noted between Mach numbers of 0.88 and 0.96 in addition to a decrease above Mach number 0.96.

NACA RM A51B28

FLIGHT MEASUREMENTS OF THE WING-DROPPING TENDENCY OF A STRAIGHT-WING JET AIRPLANE AT HIGH SUBSONIC MACH NUMBERS. Seth B. Anderson, Edward A. Ernst and Rudolph D. Van Dyke, Jr. April 24, 1951. 16p. diagrs., photo., tab. (NACA RM A51B28) (Declassified from Confidential, 9/10/54)

Flight tests conducted on a straight-wing fighter-type jet airplane showed that the wing-dropping tendency encountered at high subsonic Mach numbers was due primarily to a progressive reduction in aileron effectiveness and an increase in effective dihedral which made the lateral trim particularly sensitive to small changes in sideslip angle.

NACA RM A51C28

A COMPARISON OF THE MEASURED AND PREDICTED LATERAL OSCILLATORY CHARACTERISTICS OF A 35° SWEPT-WING FIGHTER AIRPLANE. Walter E. McNeill and George E. Cooper. July 1951. 21p. diagrs., 3 tabs. (NACA RM A51C28) (Delcassified from Confidential, 9/10/54)

Flight measurements of the lateral oscillatory characteristics of a 35° swept-wing fighter airplane were obtained at altitudes of 10,000 and 35,000 feet for an over-all Mach number range from 0.41 to 1.04. Period, time to damp to half amplitude, and ratio of angle-of-bank amplitude to angle-of-sideslip amplitude, $|\varphi|/|\beta|$, are presented as functions of Mach number for each test altitude, and are compared with values computed from wind-tunnel data and estimated stability derivatives. In general, agreement between the measured and predicted lateral oscillatory characteristics of the test airplane was satisfactory.

NACA RM A51E03

SUBSONIC MACH AND REYNOLDS NUMBER EFFECTS ON THE SURFACE PRESSURES, GAP FLOW, PRESSURE RECOVERY, AND DRAG OF A NONROTATING NACA 1-SERIES E-TYPE COWLING AT AN ANGLE OF ATTACK OF 0°. Robert M. Reynolds and Robert I. Sammonds. July 1951. 73p. diagrs., photo., 3 tabs. (NACA RM A51E03) (Declassified from Confidential, 9/10/54)

Measurements of pressure distributions on the external, inner lip, spinner, and propeller-blade-shank fairing surfaces are presented for an NACA 1-51-117 (E-type) cowling with an NACA 1-41.43-042.86 spinner suitable for a turbine-propeller installation. Ram-recovery ratios, external drag, and gap leak flow are also included. The tests were conducted with the model at an angle of attack of 0° and with the cowling not rotating. The flow characteristics are presented for a range of Mach numbers from 0.23 to 0.88 at a Reynolds number of 1.8 million and for a range of Reynolds numbers from 1.8 to 8.1 million at 0.23 Mach number. Inlet-velocity ratio was varied between 0.06 and 0.78.

NACA RM A51E14

MEASUREMENTS IN FLIGHT OF THE LONGITUDINAL CHARACTERISTICS OF TWO JET AIRCRAFT, ONE WITH A DIVING TENDENCY AND THE OTHER WITH A CLIMBING TENDENCY AT HIGH MACH NUMBERS. Seth B. Anderson. October 1951. 18p. diagrs., photos., 2 tabs. (NACA RM A51E14) (Declassified from Confidential, 9/10/54)

Flight tests conducted on two jet airplanes of generally similar configuration, one identified with a diving tendency and the other with a climbing tendency at high Mach numbers, showed that the difference in longitudinal control appears to be governed by the balance between two opposing moments; a diving tendency caused chiefly by an increase in angle of attack of the horizontal tail surfaces, and a climbing tendency due to the pitching moment of the wing.

NACA RM A51E24

AN EXPERIMENTAL INVESTIGATION AT SUBSONIC SPEEDS OF A SCOOP-TYPE AIR-INDUCTION SYSTEM FOR A SUPERSONIC AIRPLANE. Curt A. Holzhauser. July 1951. 45p. diagrs., photos. (NACA RM A51E24) (Declassified from Confidential, 9/10/54)

Measurements of ram-recovery ratio, static pressure, and boundary layer are presented at a Mach number of 0.17 for a large range of mass-flow ratios, angles of attack, and angles of sideslip for a scoop-type intake located on top of the fuselage. At 0° angles of attack and sideslip the ram-recovery ratio measured at the minimum-area station was 0.98 at a mass-flow ratio of 1.0. Above a mass-flow ratio of 1.2, the ram-recovery ratio decreased rapidly. The variation of ram-recovery ratio with angle of attack was small compared with the variation of ram-recovery ratio with angle of sideslip.

NACA RM A51F12a

INVESTIGATION OF A TRIANGULAR WING IN CONJUNCTION WITH A FUSELAGE AND HORIZONTAL TAIL TO DETERMINE DOWNWASH AND LONGITUDINAL STABILITY CHARACTERISTICS - TRANSONIC BUMP METHOD. Edwin C. Allen. August 1951. 22p. diagrs., photos. (NACA RM A51F12a) (Declassified from Confidential, 9/10/54)

This report presents effective downwash at the tail position and the static longitudinal-stability characteristics of a semispan model having a thin triangular wing of aspect ratio 2, a slender fuselage, and a thin, unswept horizontal tail. The range of Mach numbers was from 0.40 to 1.10 with a corresponding Reynolds number range of 1.0 to 1.9 million. The effects of vertical position of the horizontal tail at one longitudinal station behind the wing were investigated.

NACA RM A51G27

LONGITUDINAL FREQUENCY-RESPONSE CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE AS DETERMINED FROM FLIGHT MEASUREMENTS, INCLUDING A METHOD FOR THE EVALUATION OF TRANSFER FUNCTIONS. William C. Triplett and G. Allan Smith. September 1951. 45p. diagrs., photo. (NACA RM A51G27) (Declassified from Confidential, 9/10/54)

Data obtained from dynamic flight measurements are used to compute the longitudinal frequency-response characteristics of a 35° swept-wing airplane through the Mach number range of 0.59 to 1.05. Also presented is a general graphical method for the determination of numerical coefficients of the transfer functions from frequency-response data. The variations in these coefficients with changes in Mach number and altitude are shown.

NACA RM A51H09

STABILITY AND CONTROL MEASUREMENTS OBTAINED DURING USAF-NACA COOPERATIVE FLIGHT-TEST PROGRAM ON THE X-4 AIRPLANE (USAF NO. 46-677). Melvin Sadoff, Herman O. Ankenbruck and William O'Hare. October 1951. 38p. diagrs., photos., tab. (NACA RM A51H09) (Declassified from Confidential, 9/10/54)

Results obtained during the Air Force testing of the Northrop X-4 airplane are presented. Information is included on the stalling characteristics, the static and dynamic longitudinal- and lateral-directional stability characteristics and the lateral-control characteristics.

NACA RM A51H20a

COMPARISON OF DRAG, PRESSURE RECOVERY, AND SURFACE PRESSURE OF A SCOOP-TYPE INLET AND AN NACA SUBMERGED INLET AT TRANSONIC SPEEDS. Joseph L. Frank and Robert A. Taylor. December 1951. 63p. diagrs., photos. (NACA RM A51H20a) (Declassified from Confidential, 9/10/54)

Comparative data were obtained for a scoop-type inlet and an NACA submerged inlet at transonic speeds. The submerged inlet effected the higher ram recovery at mass-flow ratios below about 0.50. At maximum mass-flow ratio (0.92) and 0° angle of attack, the ram recovery of the two inlets was about equal. In general, the scoop-type inlet caused the greater external drag.

NACA RM A51I12

A FLIGHT EVALUATION OF THE LONGITUDINAL STABILITY CHARACTERISTICS ASSOCIATED WITH THE PITCH-UP OF A SWEPT-WING AIRPLANE IN MANEUVERING FLIGHT AT TRANSONIC SPEEDS. Seth B. Anderson and Richard S. Bray. November 1951. 33p. diagrs., photo., tab. (NACA RM A51I12) (Declassified from Confidential, 9/10/54)

Flight measurements on a swept-wing jet aircraft showed that the pitch-up encountered in a wind-up turn at transonic Mach numbers was due principally to an unstable break in the wing pitching moment associated with flow separation near the wing tip. The pitch-up encountered in slowing down in a dive-recovery maneuver was due chiefly to a reduction in wing-fuselage stability. An increase in down load for the horizontal tail was indicated with increase in Mach number for normal force-coefficient values in excess of approximately 0.2.

NACA RM A51J11

THE EFFECTS AT TRANSONIC SPEEDS OF THICKENING THE TRAILING EDGE OF A WING WITH A 4-PERCENT-THICK CIRCULAR-ARC AIRFOIL. Joseph W. Cleary and George L. Stevens. December 1951. 43p. diagrs., photo. (NACA RM A51J11) (Declassified from Confidential, 9/10/54)

Effects of systematic variation of trailing-edge thickness of a symmetrical circular-arc airfoil on lift, drag, pitching moment, base pressure, and wake pressure fluctuations were investigated for the transonic Mach number range by the wind-tunnel bump technique. Results show that for trailing-edge thickness of 0.3 of the airfoil thickness beneficial gains in lift-drag ratios can be expected at subsonic Mach numbers with no measurable increase in minimum drag. Higher lift-curve slopes were observed in the transonic Mach number range for blunt-trailing-edge airfoils as compared with circular-arc airfoils.

NACA RM A51J18

THE EFFECTIVENESS OF WING VORTEX GENERATORS IN IMPROVING THE MANEUVERING CHARACTERISTICS OF A SWEPT-WING AIRPLANE AT TRANSONIC SPEEDS. Norman M. McFadden, George A. Rathert, Jr. and Richard S. Bray. February 1952. 45p. photos., diagrs., tab. (NACA RM A51J18) (Declassified from Confidential, 9/10/54)

The effects of wing vortex generators, multiple boundary-layer fences, and extension of the outer two segments of the wing leading-edge slats on the aerodynamic characteristics of a 35° swept-wing fighter were measured in flight tests at transonic speeds and high altitudes. Significant improvements were obtained in the pitch-up and wing-dropping-tendency characteristics with certain arrangements of vortex generators.

NACA RM A51J19a

THE EFFECT OF ENTRANCE MACH NUMBER AND LIP SHAPE ON THE SUBSONIC CHARACTERISTICS OF A SCOOP-TYPE AIR-INDUCTION SYSTEM FOR A SUPERSONIC AIRPLANE. Curt A. Holzhauser. January 1952. 39p. diagrs., photos., tab. (NACA RM A51J19a) (Declassified from Confidential, 9/10/54)

This report presents the ram-recovery ratios and static-pressure distributions of a scoop-type intake with a rounded lip and with a sharp lip. The entrance Mach numbers ranged from 0 to choking for free-stream Mach numbers of 0.08 to 0.33. The wake drag coefficients of these two types of installations are compared. The ram-recovery ratio of the intake with a rounded lip was greater than with a sharp lip at the higher mass-flow ratios. When the air flow was separated in the duct, the ram-recovery ratio decreased with increasing entrance Mach numbers.

NACA RM E50H16a

INVESTIGATION OF IGNITION CHARACTERISTICS OF AN-F-32 AND TWO AN-F-58a FUELS IN SINGLE CAN-TYPE TURBOJET COMBUSTOR. Warren D. Rayle and Howard W. Douglass. October 13, 1950. 25p. photos., diagrs., 2 tabs. (NACA RM E50H16a) (Declassified from Confidential, 9/10/54)

Ignition characteristics of AN-F-32 and two AN-F-58a fuels were studied in a single can-type turbojet combustor under air-flow conditions representing engine speeds of 1600, 2500, and 4000 rpm, altitudes from sea level to 30,000 feet, ambient temperatures at sea level from 90° to -36° F, and flight Mach numbers of 0 and 0.6. Critical fuel-flow rates for ignition increased with increase in preignition engine speed, with increase in altitude, or with decrease in sea-level ambient temperature. This flow rate appears to increase in a direct relation to decrease in fuel volatility as indicated by the 10-percent-evaporated temperature.

NACA RM E51B02

COMBUSTION PROPERTIES OF ALUMINUM AS RAM-JET FUEL. J. Robert Branstetter, Albert M. Lord and Melvin Gerstein. March 28, 1951. 37p. diagrs., photos. (NACA RM E51B02) (Declassified from Confidential 9/10/54)

An experimental investigation was conducted on the combustion properties of aluminum as a fuel for use in jet-powered aircraft. Two techniques of injection were investigated. In one method aluminum powder was utilized whereas in the other aluminum wire was utilized. Aluminum powder was burned stably and at combustion efficiencies that averaged about 50 percent, although the thrust obtained was less than that obtained by burning propane at equivalent conditions. Aluminum wire was burned with about 75 percent combustion efficiency. Solid deposits in the combustors were found to be a serious obstacle to the use of aluminum as a ram-jet fuel.

NACA RM E51B08

CORRELATION OF ANALOG SOLUTIONS WITH EXPERIMENTAL SEA-LEVEL TRANSIENT DATA FOR CONTROLLED TURBINE-PROPELLER ENGINE, INCLUDING ANALOG RESULTS AT ALTITUDES. James Lazar and Wilfred L. DeRocher, Jr. August 1951. 36p. diagrs. (NACA RM E51B08) (Declassified from Confidential, 9/10/54)

A satisfactory correlation was obtained between experimental sea-level transient data and solutions from the analog representation. The analog representation is accomplished by transfer functions that were formed from a frequency-response analysis of the experimental transient data as obtained from the controlled engine. This analog representation was then used to compute system response at altitude.

NACA RM E51C02

CARBON DEPOSITION OF SEVERAL SPECIAL TURBOJET-ENGINE FUELS. Jerrold D. Wear and James W. Useller. April 10, 1951. 15p. photos., diagr., tab. (NACA RM E51C02) (Declassified from Confidential, 9/10/54)

Investigations were conducted to determine the carbon forming characteristics of MIL-F-5624 and MIL-F-5161 type fuels in a single J33 combustor and of a MIL-F-5161 fuel in a J35 full-scale engine. The carbon deposition of the fuels investigated in the single combustor could be estimated from a previously established empirical correlation with volumetric average boiling temperature and hydrogen-carbon ratio. The results indicated that MIL-F-5161 type fuels formed more carbon in the single combustor and the full-scale turbojet engine than most MIL-F-5624 type fuels, and may result in marginal operation in several turbojet engines.

NACA RM E51C14

EFFECT OF FUEL VOLATILITY ON PERFORMANCE OF TAIL-PIPE BURNER. Zelmar Barson and Arthur F. Sargent, Jr. April 30, 1951. 18p. diagrs., tab. (NACA RM E51C14) (Declassified from Confidential, 9/10/54)

Fuels having Reid vapor pressures of 6.3 and 1.0 pounds per square inch were investigated in a tail-pipe burner on an axial-flow-type turbojet engine at a simulated flight Mach number of 0.6 and altitudes from 20,000 to 45,000 feet. With the burner configuration used in this investigation, having a mixing length of only 8 inches between the fuel manifold and the flame holder, the low-vapor-pressure fuel gave lower combustion efficiency at a given tail-pipe fuel-air ratio. Because the exhaust-nozzle area was fixed, the lower efficiency resulted in lower thrust and higher specific fuel consumption. The maximum altitude at which the burner would operate was practically unaffected by the change in fuel volatility.

NACA RM E51D16

INVESTIGATION OF MECHANISMS OF BLADE FAILURE OF FORGED HASTELLOY B AND CAST STELLITE 21 TURBINE BLADES IN TURBOJET ENGINE. C. Yaker, C. F. Robards and F. B. Garrett. August 1951. 41p. diagrs., photos., 2 tabs. (NACA RM E51D16) (Declassified from Confidential, 9/10/54)

An investigation was conducted to study the mechanisms of blade failure of forced Hastelloy B and cast Stellite 21. The blades were mounted in a 16-25-6 alloy rotor and subjected to 20-minute cycles consisting of 15 minutes at rated speed and approximately 5 minutes at idle. The first failures of the Hastelloy B and Stellite 21 blades were probably the result of excessive vibratory stresses and occurred after 14.25 and 16.75 hours, respectively. After 28.75 hours of operation, all but 3 of the original 25 Hastelloy B blades had either failed or contained stress-rupture-type cracks and four of the original 27 Stellite 21 blades contained stress-rupture-type cracks.

NACA RM E51D26

ANALYSIS OF EXPERIMENTAL SEA-LEVEL TRANSIENT DATA AND ANALOG METHOD OF OBTAINING ALTITUDE RESPONSE FOR TURBINE-PROPELLER ENGINE WITH RELAY-TYPE SPEED CONTROL. George Vasu and George J. Pack. May 17, 1951. 28p. diagrs., photo. (NACA RM E51D26) (Declassified from Confidential, 9/10/54)

Correlation has been established between transient engine and control data obtained experimentally and data obtained by simulating the engine and control with an analog computer. This correlation was established at sea-level conditions for a turbine-propeller engine with a relay-type speed control. The behavior of the controlled engine at altitudes of 20,000 and 35,000 feet was determined with an analog computer using the altitude pressure and temperature generalization factors to calculate the new engine constants for these altitudes. Because the engine response varies considerably at altitude some type of compensation appears desirable and four methods of compensation are discussed.

NACA RM E51F11

ALTITUDE-IGNITION LIMIT OF A TURBOJET ENGINE USING A CONDENSER-DISCHARGE IGNITION SYSTEM. John C. Armstrong. October 1951. 5p. diagrs. (NACA RM E51F11) (Declassified from Confidential, 9/10/54)

The altitude-ignition limits of a condenser-discharge ignition system installed on a turbojet engine were determined at a flight Mach number of 0.6 using 1.1-pound Reid vapor pressure fuel. Ignition was possible up to an altitude of 55,000 feet with 4.8 joules per spark and 6 sparks per second.

NACA RM E51F18

VELOCITY AND TEMPERATURE FIELDS IN CIRCULAR JET EXPANDING FROM CHOKED NOZZLE INTO QUIESCENT AIR. Morris D. Rousso and Fred D. Kochendorfer. July 1951. 34p. diagrs., photos. (NACA RM E51F18. Formerly RM E50E03a) (Declassified from Confidential, 9/10/54)

The Mach number and temperature profiles in jets expanding from convergent and convergent-divergent nozzles are presented for several values of nozzle-exit pressure ratio. The effects of jet temperature, Reynolds number, and humidity on jet spreading are briefly evaluated. The results indicated that the downstream Mach number profiles for a heated jet are slightly narrower than those for an unheated jet, whereas the downstream temperature profiles were unaffected by nozzle temperature change, and that the effects of Reynolds number and humidity were negligible.

NACA RM L51E01

CONTRIBUTIONS OF WING, TAIL, AND FUSELAGE TO THE AERODYNAMIC CHARACTERISTICS OF A SEMISPAN MODEL OF A SUPERSONIC AIRPLANE CONFIGURATION AT TRANSONIC SPEEDS FROM TESTS BY THE NACA WING-FLOW METHOD. Norman S. Silsby and James M. McKay. July 1951. 34p. diagrs., photos., tab. (NACA RM L51E01) (Declassified from Confidential, 9/10/54)

An investigation has been made by the NACA wing-flow method at transonic speeds to determine the contributions of wing, tail, and fuselage to the aerodynamic characteristics of a semispan airplane model having a long slender fuselage and a straight wing and tail of low aspect ratio with faired symmetrical double-wedge airfoil sections 4.6-percent chord in thickness. Lift, drag, and pitching moments were obtained for the complete model, wing-fuselage configuration, fuselage-tail configuration, and fuselage alone. The Mach number range of the tests was from 0.60 to 1.13, and the Reynolds number range was from about 0.3×10^6 to 0.7×10^6.

NACA RM L51E07

SYSTEM ANALYSES AND AUTOPILOT DESIGN FOR AUTOMATIC ROLL STABILIZATION OF A SUPERSONIC PILOTLESS AIRCRAFT. Jacob Zarovsky. July 1951. 55p. diagrs., tab. (NACA RM L51E07) (Declassified from Confidential, 9/10/54)

Automatic roll stabilization system analysis and roll autopilot detail design have been conducted for a supersonic pilotless aircraft with twin jet engines. The autopilots investigated were a gyro-actuated control, a gyro-actuated control with a rate-sensing device (to provide additional damping), and an electronic hydraulic autopilot. It was concluded that an electronic-hydraulic roll autopilot with a passive electrical network and suitable gain adjustment appears to be a practical and realizable means of providing the required system roll stabilization characteristics.

NACA RM L51E09

WING-FLOW STUDY OF PRESSURE-DRAG REDUCTION AT TRANSONIC SPEED BY PROJECTING A JET OF AIR FROM THE NOSE OF A PROLATE SPHEROID OF FINENESS RATIO 6. Mitchell Lopatoff. October 1951. 20p. photos., diagrs., tab. (NACA RM L51E09) (Declassified from Confidential, 9/10/54)

Contains studies by NACA wing-flow method of pressure-drag reduction obtained at transonic speed by projecting a jet of air from the nose of a prolate spheroid. Comparisons of pressure distributions with and without the jet are made. Shadowgraphs of the model obtained in a small supersonic tunnel at a constant Mach number of 1.5 while the thrust of the jet was varied are presented.

NACA RM L51E18

RESULTS OF FLIGHT TESTS TO DETERMINE DRAG OF PARABOLIC AND CONE-CYLINDER BODIES OF VERY LARGE FINENESS RATIOS AT SUPERSONIC SPEEDS. Clement J. Welsh and Carlos A. deMoraes. August 1951. 17p. diagrs., photos. (NACA RM L51E18) (Declassified from Confidential, 9/10/54)

Results of free-flight investigation at supersonic speeds to determine zero-lift drag of bodies of revolution with varying fineness ratios are presented for both parabolic and cone-cylinder bodies.

NACA RM L51E25a

A PRELIMINARY INVESTIGATION OF COMBUSTION WITH ROTATING FLOW IN AN ANNULAR COMBUSTION CHAMBER. Ira R. Schwartz. September 1951. 18p. diagrs., photos. (NACA RM L51E25a) (Declassified from Confidential, 9/10/54)

A preliminary investigation of flame-stability and flame-extinction characteristics of a propane-air mixture in an annular combustion chamber was conducted with both straight and rotational flow. The rotating mixture burned at higher axial-inlet stream velocities and with more stable flames than could be obtained with straight-flow burning. Unsteady burning, accompanied by the pulsations and intense noise usually present in straight-flow burning, was not present in the rotating-flow burning. The external axial-flame length was appreciably less and the flame divergence was greater with rotating flow.

NACA RM L51F01

COMPARISON OF AIRFOIL SECTIONS ON TWO TRIANGULAR-WING-FUSELAGE CONFIGURATIONS AT TRANSONIC SPEEDS FROM TESTS BY THE NACA WING-FLOW METHOD. Albert W. Hall and James M. McKay. August 1951. 23p. diagrs., photo., tab. (NACA RM L51F01) (Declassified from Confidential, 9/10/54)

Tests were made by the NACA wing-flow method at transonic speeds on four triangular-wing-fuselage models. Two models had wings of aspect ratio 2.31 with NACA 65009 and 9-percent-thick biconvex sections and two models had wings of aspect ratio 4.00 with NACA 65006 and 6-percent-thick double-wedge sections. Lift, drag, pitching-moment, and angle-of-attack measurements are presented for a Mach number range of 0.75 to 1.075. The test Reynolds number was approximately 1.5×10^6.

NACA RM L51F01a

STATIC LATERAL STABILITY CHARACTERISTICS OF A 1/10-SCALE MODEL OF THE X-1 AIRPLANE AT HIGH SUBSONIC MACH NUMBERS. Richard E. Kuhn and James W. Wiggins. August 1951. 25p. diagrs., photos. (NACA RM L51F01a) (Declassified from Confidential, 9/10/54)

Results are presented of an investigation made in the Langley high-speed 7- by 10-foot tunnel to determine the high-speed static lateral and directional characteristics of a 1/10-scale model of the X-1 transonic research airplane from a Mach number of 0.40 to 0.88.

NACA RM L51F06a

AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A TAPERED 45° SWEPTBACK WING OF ASPECT RATIO 3 HAVING A FULL-SPAN FLAP-TYPE CONTROL. TRANSONIC-BUMP METHOD. Vernard E. Lockwood and Joseph E. Fikes. August 1951. 35p. diagrs. (NACA RM L51F06a) (Declassified from Confidential, 9/10/54)

Lift, drag, pitching-moment, rolling moment, and flap hinge-moment coefficients were obtained by the transonic-bump method on a wing having a quarter chord sweepback of 45.58°, aspect ratio of 3, a taper ratio of 0.5 and an NACA 64A010 section employing a 0.254-chord full-span flap. The investigation was made at angles of attack of 0°, 4°, and 8°, flap deflections from -27° to 5°, and Mach numbers from 0.6 to 1.17. The investigation was made with the gap at the nose of the flap both sealed and unsealed. The results from the bumps, an investigation of a large model at higher Reynolds number, and available estimation methods are compared.

NACA RM L51F08

A METHOD FOR THE DESIGN OF SWEPTBACK WINGS WARPED TO PRODUCE SPECIFIED FLIGHT CHARACTERISTICS AT SUPERSONIC SPEEDS. Warren A. Tucker. September 1951. 52p. diagrs., 2 tabs. (NACA RM L51F08) (Declassified from Confidential, 9/10/54)

A method is presented for designing sweptback wings to be self-trimming at a given set of flight conditions. This characteristic is achieved by warping the wing in a particular manner, that is, by giving the wing a certain combination of angle of attack, twist, and camber. The method applied directly to a wide class of sweptback wings. The application to any specific wing is simplified to a routine computational procedure, and a discussion is given of some points to be considered in the application to a practical case. Several illustrative examples are worked out, and the resulting wings are shown to be feasiable to construct.

NACA RM L51F08a

SMALL-SCALE INVESTIGATION AT TRANSONIC SPEEDS OF THE EFFECTS OF THICKENING THE INBOARD SECTION OF A 45° SWEPTBACK WING OF ASPECT RATIO 4, TAPER RATIO 0.3, AND NACA 65A006 AIRFOIL SECTION. Kenneth P. Spreemann and William J. Alford, Jr. August 1951. 21p. diagrs., photo. (NACA RM L51F08a) (Declassified from Confidential, 9/10/54)

An investigation was conducted in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.60 to 1.08 to determine the aerodynamic effects of thickening the inboard 40 percent of a semispan wing with the quarter-chord line swept back 45°, an aspect ratio of 4, a taper ratio of 0.3, and an NACA 64A006 airfoil section. Lift, drag, pitching moment, and bending moment were obtained for the two wings. Also included in the paper are some comparisons of experimental results with theory, corrected to elastic conditions.

NACA RM L51F12

TABULATED PRESSURE COEFFICIENTS AND AERODYNAMIC CHARACTERISTICS MEASURED IN FLIGHT ON THE WING OF THE D-558-I RESEARCH AIRPLANE THROUGH A MACH NUMBER RANGE OF 0.80 TO 0.89 AND THROUGHOUT THE NORMAL-FORCE-COEFFICIENT RANGE AT MACH NUMBERS OF 0.61, 0.70, 0.855, AND 0.88. Earl R. Keener and Rozalia M. Bandish. August 1951. 43p. diagrs., photos., 7 tabs. (NACA RM L51F12) (Declassified from Confidential, 9/10/54)

Presents tabulated pressure coefficients and aerodynamic characteristics obtained in flight from pressure distributions over six chordwise rows of orifices on a wing of the Douglas D-558-I research airplane (BuAero No. 37972). It includes data obtained throughout a Mach number range of 0.80 to 0.89 and throughout the normal-force-coefficient range at M = 0.61, 0.70, 0.855, and 0.88.

NACA RM L51F19

THEORETICAL ANALYSES TO DETERMINE UNBALANCED TRAILING-EDGE CONTROLS HAVING MINIMUM HINGE MOMENTS DUE TO DEFLECTION AT SUPERSONIC SPEEDS. Kennith L. Goin. November 1952. 52p. diagrs., tab. (NACA RM L51F19) (Declassified from Confidential, 9/10/54)

Theoretical analyses have been made to determine the plan forms of unbalanced trailing-edge flap-type controls having minimum hinge moments due to deflection and requiring minimum work to overcome the hinge moments due to deflection at supersonic speeds. Ratios of lift and rolling moment to hinge moment and lift and rolling moment to deflection work at fixed values of lift and rolling effectiveness were used as bases for the analyses. The effects of control plan form, control location, and Mach number have been considered.

NACA RM L51F26

EFFECTS OF PROPELLER-SHANK GEOMETRY AND PROPELLER-SPINNER-JUNCTURE CONFIGURATION ON CHARACTERISTICS OF AN NACA 1-SERIES COWLING-SPINNER COMBINATION WITH AN EIGHT-BLADE DUAL-ROTATION PROPELLER. Arvid L. Keith, Jr., Gene J. Bingham and Arnold J. Rubin. September 1951. 73p. diagrs., photos., 5 tabs. (NACA RM L51F26) (Declassified from Confidential, 9/10/54)

Results of low-speed investigation of aerodynamic characteristic of NACA 1-series cowling-spinner combination equipped with several eight-blade dual-rotation propellers differing in shank-thickness ratio are presented. Studies of sealed and faired propeller spinner junctures, four junctures that permit blade rotation, and two methods for retarding spinner boundary-layer separation are included.

NACA RM L51F28

EFFECTS OF SPANWISE THICKNESS VARIATION ON THE TRANSONIC AERODYNAMIC CHARACTERISTICS OF WINGS HAVING 35° OF SWEEPBACK, ASPECT RATIO 4, AND TAPER RATIO 0.60. William D. Morrison, Jr. and Paul G. Fournier. September 1951. 21p. diagrs., photo. (NACA RM L51F28) (Declassified from Confidential, 9/10/54)

The aerodynamic characteristics of a wing tapered in thickness from 6 percent at the root to 2 percent at the tip having 35° sweepback, aspect ratio 4, and taper ratio 0.60 have been determined by a reflection plane technique over a Mach number range from 0.60 to 1.08 at a Reynolds number of about 650,000. The results of this investigation are compared with those of a wing of identical plan form but of a constant thickness ratio. Theoretical subsonic and low-supersonic calculation of lift-curve slope, aerodynamic center, and lateral center-of-lift location are compared with experimental results.

NACA RM L51F29

BASE PRESSURES MEASURED ON SEVERAL PARABOLIC-ARC BODIES OF REVOLUTION IN FREE FLIGHT AT MACH NUMBERS FROM 0.8 TO 1.4 AND AT LARGE REYNOLDS NUMBERS. Ellis Katz and William E. Stoney, Jr. October 1951. 20p. diagrs., photos. (NACA RM L51F29) (Declassified from Confidential, 9/10/54).

Base pressures were measured on several fin stabilized bodies of parabolic-arc profile in free flight at Mach numbers from 0.8 to 1.4 and at Reynolds numbers from 20 to 130 million. The bodies varied in length from 6 to 25 diameters and had afterbodies which converged to base areas equal to 19.1 percent of the frontal areas. Pressures were also measured on the side of the bodies immediately ahead of the bases.

NACA RM L51G03

AN INVESTIGATION AT TRANSONIC SPEEDS OF THE EFFECTS OF CONTROL CHORD AND SPAN ON THE CONTROL CHARACTERISTICS OF A TAPERED WEDGE-TYPE WING OF ASPECT RATIO 2.5. TRANSONIC-BUMP METHOD. Raymond D. Vogler, Vernard E. Lockwood and Thomas R. Turner. September 1951. 36p. diagrs. (NACA RM L51G03) (Declassified from Confidential, 9/10/54)

This paper presents the results of a control investigation of 25-, 35-, and 45-percent-chord controls of various spanwise magnitudes on an unswept double-wedge-type wing of aspect ratio 2.5 and taper ratio of 0.625. Rolling and pitching moments and lift of the semispan wing-fuselage combination were obtained through a Mach range of 0.6 to 1.18 and at a Reynolds number near 1.2×10^6. The control deflections ranged from 0° to 15°. The investigation was conducted in the Langley high-speed 7- by 10-foot tunnel using the transonic bump.

NACA RM L51G09

PRELIMINARY INVESTIGATION OF THE EFFECTS OF RECTANGULAR VORTEX GENERATORS ON THE PERFORMANCE OF A SHORT 1.9:1 STRAIGHT-WALL ANNULAR DIFFUSER. Charles C. Wood. October 1951. 27p. diagrs., photo., tab. (NACA RM L51G09) (Declassified from Confidential, 9/10/54)

Results are presented of a preliminary investigation of vortex generators introduced into the region of boundary layer near the inlet of a short annular diffuser to increase turbulent mixing in an attempt to prevent separation and resulting adverse effects. Rectangular noncambered airfoils were used as vortex generators and were varied in chord, span, angle of attack, number, and location. Some of the vortex generator arrangements resulted only in small increases to diffuser performance, while other arrangements resulted in substantial increases. The effect of one of the better vortex-generator arrangements was to eliminate separation of the flow entirely and to increase the diffuser effectiveness 17 percent.

NACA RM L51G20

A CORRELATION OF EXPERIMENTAL ZERO-LIFT DRAG OF RECTANGULAR WINGS WITH SYMMETRICAL NACA 65-SERIES AIRFOIL SECTIONS BY MEANS OF THE TRANSONIC SIMILARITY LAW FOR WINGS OF FINITE ASPECT RATIO. Edward C. B. Danforth. September 1951. 20p. diagrs. (NACA RM L51G20) (Declassified from Confidential, 9/10/54)

This paper contains a correlation of zero-lift transonic pressure drag of rectangular wings of finite aspect ratio by means of a transonic similarity law derived in NACA TN 2273. The data correlated were for wings of exposed aspect ratio between 1.12 and 6.25 and thickness ratios between 0.03 and 0.12, all with symmetrical NACA 65-series airfoil sections.

NACA RM L51H02

A THEORETICAL INVESTIGATION OF THE INFLUENCE OF AUTOPILOT NATURAL FREQUENCY UPON THE DYNAMIC PERFORMANCE CHARACTERISTICS OF A SUPERSONIC CANARD MISSILE CONFIGURATION WITH A PITCH-ATTITUDE CONTROL SYSTEM. Anthony L. Passera. October 1951. 32p. diagrs., photos., 2 tabs. (NACA RM L51H02) (Declassified from Confidential, 9/10/54)

A theoretical investigation is made to determine the effects of the natural frequency of a single-degree-of-freedom autopilot upon the dynamic performance characteristics of a supersonic canard missile configuration with rate-damping and pitch-attitude control system. These effects are presented in the form of pitch-angle, control-surface deflection, and normal acceleration transients for several flight conditions in response to a unit step attitude command signal.

NACA RM L51H16a

LOW-SPEED WIND-TUNNEL INVESTIGATION OF A FIXED AND A FREE-FLOATING WING-TIP AILERON ON A WING WITH LEADING EDGE SWEPT BACK 51.3°. R. G. MacLeod. February 1952. 17p. diagrs., photo., tab. (NACA RM L51H16a) (Declassified from Confidential, 9/10/54)

Contains results of a low-speed wind-tunnel investigation of a fixed and a free-floating wing-tip aileron on a wing with leading edge swept back 51.3°. Results indicate that the rolling effectiveness of both ailerons was maintained up to very large angles of attack while the yaw due to aileron deflection was more favorable for the free-floating aileron.

NACA RM L51H22

AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A 60° DELTA WING EQUIPPED WITH A CONSTANT-CHORD FLAP-TYPE CONTROL WITH AND WITHOUT AN UNSHIELDED HORN BALANCE. TRANSONIC-BUMP METHOD. Harleth G. Wiley and Leon Zontek. September 1952. 25p. diagrs. (NACA RM L51H22) (Declassified from Confidential, 9/10/54)

This paper presents the aerodynamic characteristics of a 60° delta wing of aspect ratio 2.31, taper ratio 0, and an NACA 65-006 airfoil section, which was equipped with a constant-chord control, with and without an unshielded triangular horn balance. Lift, pitching moment, and hinge moment were obtained at various angles of control deflection and angles of attack for both types of controls through a Mach number range of 0.6 to 1.18.

NACA RM L51H23

THE EFFECTS ON THE AERODYNAMIC CHARACTERISTICS OF REVERSING THE WING OF A TRIANGULAR WING-BODY COMBINATION AT TRANSONIC SPEEDS AS DETERMINED BY THE NACA WING-FLOW METHOD. James M. McKay and Albert W. Hall. October 1951. 22p. diagrs., photo., 2 tabs. (NACA RM L51H23) (Declassified from Confidential, 9/10/54)

Tests were made by the NACA wing-flow method on two triangular wing-fuselage models of low aspect ratio with 6-percent-thick biconvex sections. On one model the apex angle of the wing was forward and on the other the apex angle was trailing. Lift, drag, pitching moment, and angle-of-attack measurements are presented for a Mach number range of 0.75 to 1.075. The test Reynolds number was approximately 1.5×10^6.

NACA RM L51H27

INVESTIGATION OF WING-TIP AILERONS ON A 51.3° SWEPTBACK WING AT TRANSONIC SPEEDS BY THE TRANSONIC-BUMP METHOD. William C. Moseley, Jr. and James M. Watson. November 1951. 60p. diagrs. (NACA RM L51H27) (Declassified from Confidential, 9/10/54)

Three wing-tip ailerons were tested through the transonic range on a 51.3° sweptback wing. One was a triangular wing tip deflectable about an axis normal to the leading edge of the wing; the second was a triangular tip added to the basic wing; and the third, utilizing the extended tip area, was obtained by deflecting the area aft of a spanwise axis through the 0.50-tip-chord station of the basic wing. The last two ailerons provided lateral control over the Mach number range at low angles of attack.

NACA RM L51H28

AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A WING HAVING 45° SWEEP, ASPECT RATIO 8, TAPER RATIO 0.45, AND AIRFOIL SECTIONS VARYING FROM THE NACA 63A010 SECTION AT THE ROOT TO THE NACA 63A006 SECTION AT THE TIP. William D. Morrison, Jr. and Paul G. Fournier. January 1952. 22p. diagrs., photo. (NACA RM L51H28) (Declassified from Confidential, 9/10/54)

The aerodynamic characteristics of a wing tapered in thickness ratio from 10 percent at the root chord to 6 percent at the tip chord, having 45° sweepback, aspect ratio 8, and taper ratio 0.45 have been determined by a reflection-plane technique over a Mach number range from 0.60 to 1.05 at a Reynolds number of about 500,000. The results of this investigation are compared with those obtained for a wing of identical plan form but of a constant 12-percent section thickness. Theoretical subsonic calculations of lift-curve slope, and aerodynamic-center and lateral-center-of-lift locations are compared with the experimental results.

NACA RM L51H29

THE EFFECT OF RAKING THE AILERON TIPS ON THE LATERAL-CONTROL AND HINGE-MOMENT CHARACTERISTICS OF A 20-PERCENT-CHORD PARTIAL-SPAN OUTBOARD AILERON ON A WING WITH LEADING EDGE SWEPT BACK 51.3°. Alexander D. Hammond. November 1951. 41p. diagrs., photo., tab. (NACA RM L51H29) (Declassified from Confidential, 9/10/54)

A wind-tunnel investigation at low speed was made to determine the lateral-control and hinge-moment characteristics of an unsealed plain-radius-nose 20-percent-chord flat-sided partial-span outboard aileron having various plan forms on a wing with the leading edge swept back 51.3°, aspect ratio 3.06, taper ratio 0.49, and NACA 65_1-012 airfoil sections perpendicular to the 55.6-percent-chord line. The results of the investigation indicate that, for ailerons having the same area, plan form has little or no effect on the variation of rolling-moment coefficient with aileron deflection. Changes in the aileron plan form, however, have an appreciable effect on the hinge-moment parameter C_{h_δ}.

NACA RM L51H30

SUMMARY OF RESULTS OBTAINED BY TRANSONIC-BUMP METHOD ON EFFECTS OF PLAN FORM AND THICKNESS OF LIFT AND DRAG CHARACTERISTICS OF WINGS AT TRANSONIC SPEEDS. Edward C. Polhamus. November 1951. 33p. diagrs., tab. (NACA RM L51H30) (Declassified from Confidential, 9/10/54)

This paper presents a summary of the effects of plan form and thickness on the lift and drag characteristics of wings at transonic speeds and comparisons with subsonic, transonic, and supersonic theories. The data considered in this summary were obtained during a transonic research program conducted in the Langley high-speed 7- by 10-foot tunnel by the transonic bump method. The Reynolds numbers of the tests were generally less than 1×10^6.

NACA RM L51I06

EFFECTS OF HORIZONTAL-TAIL POSITION, AREA, AND ASPECT RATIO ON LOW-SPEED STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 60° TRIANGULAR-WING MODEL HAVING VARIOUS TRIANGULAR-ALL-MOVABLE HORIZONTAL TAILS. Byron M. Jaquet. December 1951. 61p. diagrs., photo., tab. (NACA RM L51I06) (Declassified from Confidential, 9/10/54)

A low-speed investigation (Mach number of 0.17 and Reynolds number of 2.06×10^6) was made in the Langley stability tunnel to determine the static longitudinal stability and control characteristics of a 60° triangular-wing model having various all-movable triangular horizontal tails. Effects of tail length, height, area, and aspect ratio are presented. All-movable tails are compared with constant-chord flaps and half-delta tip controls.

NACA RM L51I21

SMALL-SCALE INVESTIGATION OF THE EFFECTS OF TWIST AND CAMBER ON THE AERODYNAMIC CHARACTERISTICS OF A 60° 42' SWEPTBACK WING OF ASPECT RATIO 1.94. Kenneth P. Spreemann and William J. Alford, Jr. January 1952. 19p. diagrs., photo., tab. (NACA RM L51I21) (Declassified from Confidential, 9/10/54)

An investigation of two semispan wings having the same plan form was conducted in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.59 to 1.10 to determine the effects of twist and camber on the aerodynamic characteristics of a sweptback wing rotated from its original design position. This paper presents the results of the investigation of the two semispan wings swept back 60° 42'; one wing was untwisted and uncambered, the other incorporated twist and camber. The wings had aspect ratios of 1.94, taper ratios of 0.44, and NACA 64A-series airfoil sections tapered in thickness. Lift, drag, pitching moment, and bending moment were obtained for the two wings.

NACA Rept. 1150

CONSIDERATIONS ON THE EFFECT OF WIND-TUNNEL WALLS ON OSCILLATING AIR FORCES FOR TWO-DIMENSIONAL SUBSONIC COMPRESSIBLE FLOW. Harry L. Runyan and Charles E. Watkins. 1953. ii, 7p. diagrs. (NACA Rept. 1150. Formerly TN 2552)

This paper treats the effect of wind-tunnel walls on the oscillating two-dimensional air forces in a compressible medium. The walls are simulated by the usual method of placing images at appropriate distances above and below the wing. An important result shown is that, for certain conditions of wing frequency, tunnel height, and Mach number, the tunnel and wing may form a resonant system so that the forces on the wing are greatly changed from the condition of no tunnel walls.

NACA Rept. 1162

LIFT DEVELOPED ON UNRESTRAINED RECTANGULAR WINGS ENTERING GUSTS AT SUBSONIC AND SUPERSONIC SPEEDS. Harvard Lomax. 1954. ii, 16p. diagrs., 5 tabs. (NACA Rept. 1162. Formerly TN 2925)

Lift forces induced by a vertical gust are estimated on the basis of theoretical calculations. The effects of pitching and wing bending are neglected and only wings of rectangular plan form are considered. However, the effects of Mach number (from 0 to 2) and aspect ratio (2 to ∞) are included, and solutions are given by means of which the response to gusts having arbitrary streamwise gradients can be calculated. Results are presented for sharp-edged and triangular gusts and various wing-air density ratios.

NACA TM 1376

EXPERIMENTS ON TAIL-WHEEL SHIMMY. (Experimentelle Untersuchungen über das Spornradflattern). O. Dietz and R. Harling. October 1954. 81p. diagrs., photos. (NACA TM 1376. Trans. from Zentrale für weissenschaftliches Berichtswesen der Luftfahrtforschung, Berlin, FB 1320)

Model tests on the "running belt" and tests with a full-scale tail wheel were made on a rotating drum as well as on a runway in order to investigate the causes of the undesirable shimmy phenomena frequently occurring on airplane tail wheels, and the means of avoiding them. The small model (scale 1:10) permitted simulation of the mass, moments of inertia, and fuselage stiffnesses of the airplane and determination of their influence on the shimmy, whereas by means of the larger model with pneumatic tires (scale 1:2) more accurate investigations were made on the tail wheel itself. The results of drum and road tests show good agreement with one another and with the model values. Detailed investigations were made regarding the dependence of the shimmy tendency on trail, rolling speed, load, size of tires, ground friction, and inclination of the swivel axis; furthermore, regarding the influence of devices with restoring effect on the tail wheel, and the friction damping required for prevention of shimmy. Finally observations from slow-motion pictures are reported and conclusions drawn concerning the influence of tire deformation.

NACA TN 3245

CALCULATED SUBSONIC SPAN LOADS AND RESULTING STABILITY DERIVATIVES OF UNSWEPT AND 45° SWEPTBACK TAIL SURFACES IN SIDESLIP AND IN STEADY ROLL. M. J. Queijo and Donald R. Riley. October 1954. 110p. diagrs., 2 tabs. (NACA TN 3245)

Subsonic span loads have been calculated for a systematic series of unswept and 45° sweptback tail surfaces by the discrete-horseshoe-vortex method. Results are presented as charts of span loads and the resulting contribution to the side-force and rolling derivatives. Geometric variables covered in the investigation included vertical- and horizontal-tail aspect ratios and vertical position and dihedral of the horizontal tail for various tail assemblies in sideslip and steady roll. Also presented is an extensive table of values of sidewash due to a rectangular vortex.

NACA TN 3247

AN EVALUATION OF AN ACCELEROMETER METHOD FOR OBTAINING LANDING-GEAR DRAG LOADS. Jerome G. Theisen and Philip M. Edge, Jr. October 1954. 22p. diagrs., photos. (NACA TN 3247)

An evaluation is made of applied ground drag loads obtained by means of angular-acceleration measurements on the wheel of a landing gear together with

vertical-acceleration measurements on the upper and lower masses. The data are obtained during forward-speed landing impacts and drop tests in the Langley impact basin. The results obtained by using this method showed good agreement with values obtained simultaneously from specially constructed dynamometers.

NACA TN 3248

AN EXPERIMENTAL AND THEORETICAL INVESTIGATION OF THE ANISOTROPY OF 3S ALUMINUM-ALLOY SHEET IN THE PLASTIC RANGE. Arthur J. McEvily, Jr. and Philip J. Hughes. October 1954. 45p. diagrs., photos., 4 tabs. (NACA TN 3248)

The results of tension and compression tests on 3S aluminum-alloy sheet are presented together with values of Poisson's ratio in the plastic range. Crystallographic anisotropy was found to be responsible for the variation in Poisson's ratio in the width and thickness directions of specimens alined at various directions with respect to the rolling direction in the plane of the sheet. X-ray diffraction studies of annealed specimens were made and pole figures showing the type of preferred orientation were drawn. A theoretical analysis was made to account for the observed anisotropy based on the behavior of single crystals and the texture of the sheet. An independent check of the theory is afforded through comparison with experimental data on cubically alined copper sheet.

NACA TN 3249

THE HYDRODYNAMIC CHARACTERISTICS OF AN ASPECT-RATIO-0.125 MODIFIED RECTANGULAR FLAT PLATE OPERATING NEAR A FREE WATER SURFACE. John A. Ramsen and Victor L. Vaughan, Jr. October 1954. 32p. diagrs. (NACA TN 3249)

Results of an investigation of the hydrodynamic force characteristics of an aspect-ratio-0.125 modified flat plate on a single strut operating near a free water surface are presented. Comparisons between these data and similar data from previous tests on plates having aspect ratios of 1.00 and 0.25 are presented; these comparisons give the effects of aspect ratio on the characteristics. The experimental effects of varying the depth of submersion and angle of attack are shown. The effects of cavitation at the leading edge and of the planing-bubble type of high-angle separation are presented. Comparisons are also presented between the experimental lift for all three aspect ratios at large depths of submersion and several theoretical methods of predicting the lift.

NACA TN 3250

AN EXPERIMENTAL INVESTIGATION OF THE EFFECT OF WHEEL PREROTATION ON LANDING-GEAR DRAG LOADS. Dexter M. Potter. October 1954. 19p. diagrs., photos., tab. (NACA TN 3250)

The effect of prerotation on the wheel spin-up drag loads on a small landing gear during landings has been investigated in the Langley impact basin. The results showed that, at the forward speed of the test (approximately 85 fps), even partial prerotation resulted in a reduction in both the drag load and the vertical load. At very high speeds, however, consideration of the variation of drag load with forward speed as obtained in a previous investigation indicated that large amounts of prerotation must be used in order to assure a reduction in drag load.

NACA TN 3263

LIFT AND MOMENT EQUATIONS FOR OSCILLATING AIRFOILS IN AN INFINITE UNSTAGGERED CASCADE. Alexander Mendelson and Robert W. Carroll. October 1954. 46p. diagrs., 3 tabs. (NACA TN 3263)

Aerodynamic coefficients similar to those of the isolated airfoil are obtained as functions of the cascade geometry and the phasing between successive blades; the phasings considered are zero, 90°, and 180°. These aerodynamic coefficients are plotted for the special case when all the airfoils are vibrating in bending in phase (360° phasing). It is shown that the effect of cascading for this case is to reduce greatly the aerodynamic damping.

NACA TN 3265

VAPORIZATION RATES AND DRAG COEFFICIENTS FOR ISOOCTANE SPRAYS IN TURBULENT AIR STREAMS. Robert D. Ingebo. October 1954. 39p. diagrs., photos., 3 tabs. (NACA TN 3265)

Drop-size distribution and drop-velocity data were obtained for isooctane sprays in turbulent air streams using a droplet camera developed at the NACA Lewis laboratory. Experimental spray vaporization rates, based on the mean diameter, correlated single-droplet vaporization rates. An empirical expression was derived for isooctane droplet drag coefficients.

AN EXPERIMENTAL STUDY OF THREE-DIMENSIONAL HIGH-SPEED AIR CONDITIONS IN A CASCADE OF AXIAL-FLOW COMPRESSOR BLADES. K. W. Todd. 1954. 34p. diagrs., photos. (ARC R & M 2792; ARC 12,711; 12,308)

Detailed investigations have been made by optical and physical methods in a high-speed wind tunnel of the flow characteristics of two compressor cascades. In part 1 a representative high-camber cascade was examined at zero incidence over entry air velocities ranging from low to critical. Traverses were made of discharge angles and wake losses at all heights so that a relation between two- and three-dimensional losses could be obtained. In part 2 the blade and passage design was conditioned by the findings of part 1, with the aim of so modifying the cascade that its efficiency in the critical flow region would be improved.

Aeronautical Research Council (Gt. Brit.)
A NEW LAW OF SIMILARITY FOR PROFILES, VALID IN THE TRANSONIC REGION. K. Oswatitsch. 1954. 12p. diagrs. (ARC R & M 2715; ARC 10,807. Formerly RAE Tech. Note Aero 1902)

A new law of similarity is given, valid for slender profiles in mixed transonic flow with negligible viscosity, according to which the cube of the Prandtl factor of any critical Mach number is proportional to the thickness ratio. It is shown that this rule, and that of von Kármán for flow at sonic speed, are valid for shock waves within the range over which the shock loss is proportional to the cube of the pressure rise. Experimental pressure distributions plotted according to this rule show good agreement, except for the position of the shock wave on the surface.

TREATMENT OF THE STAGNATION POINT IN ARITHMETICAL METHODS. A. Thom. 1954. 10p. diagrs., 2 tabs. (ARC R & M 2807. Formerly ARC 14,118; FM 1577; Oxford Univ., Engineering Lab. No.53)

In using any of the relaxation techniques near a stagnation point difficulties arise if the variable is log 1/q. This tends to infinity and the difference equation no longer represents adequately the differential equation without special modification. Methods are given whereby larger squares can be used than had been previously practicable. As little variation as possible has been introduced into the procedure so that if an electronic calculator is used, the alterations to the circuits would be reduced to a minimum.

VELOCITY DISTRIBUTION ON THIN TAPERED WINGS WITH FORE-AND-AFT SYMMETRY AND SPANWISE CONSTANT THICKNESS RATIO AT ZERO INCIDENCE. S. Neumark and J. Collingbourne. 1954. 43p. diagrs., 6 tabs. (ARC R & M 2858; ARC 14,474. Formerly RAE Aero 2432)

This report is a continuation of three earlier ones by the present authors and contains a theoretical investigation of subsonic flow past thin tapered unswept wings (of full- or cropped-rhombus plan form), at zero angle of attack. The method used is that of linear perturbation in which the wing is replaced by a system of sources and sinks; the required velocity field is then approximately obtained as that of the velocity components, in the plane of the chord lines, given by this source system. The supervelocity is then determined by direct integration.

METHODS OF APPROACHING AN ACCURATE THREE-DIMENSIONAL POTENTIAL SOLUTION FOR A WING. H. C. Garner. 1954. 19p. diagrs., 2 tabs. (ARC R & M 2721. Formerly ARC 11,802; Perf.489; FM 1293)

Attention is given to some fundamental aspects of the vortex-sheet theory for determining the distribution of lift on a finite wing. The accuracy and limitations of some existing approximate forms of the theory are discussed. With special reference to the labor of computation an iterative approach to an accurate solution is suggested, and the general mathematical expression for the distribution of lift required to give an exact solution for a Vee wing is considered.

TRANSDUCTORS WITH VOLTAGE RE-SET CONTROL. A. G. Milnes. March 1954. 21p. diagrs. (RAE Tech.Note EL.67)

Voltage reset transductors have half-cycle delay times but this response is at the expense of very limited amplification. Factors influencing the performance are discussed and a voltage feedback technique is examined. When preamplification is required thermionic triodes, transistors or conventional transductors may be used; but the control voltage and current conditions of a reset circuit may present matching problems. Applications as computing elements, as synchro-coupling units, as lead networks and for multiplication of two voltages are discussed.

DESIGN OF TRIDAC (A THREE-DIMENSIONAL SIMULATOR FOR GUIDED MISSILES). PART VI - MONITORING TECHNIQUES. K. C. Garner. May 1954. 18p. diagrs., photos. (RAE Tech.Note GW 318)

Monitoring systems have been developed to detect certain fault conditions in the operation of the majority of the individual components comprising TRIDAC. Voltage variations or failures in the power supplies to the d.c. amplifiers, and abnormal drift voltages which may occur in the d.c. amplifiers are suitably indicated. Monitoring is also provided to detect saturation of the signal output from each of the d.c. amplifiers. The location in the simulator at which any of these faults occur is displayed on a system of warning lights. The basic principles of these, and other associated facilities, considered of importance to fault location and operational procedure, are discussed.

EXPERIMENTS ON THE FLOW INTO A SWEPT LEADING-EDGE INTAKE AT ZERO FORWARD SPEED WITH NOTES ON THE WIDER USES OF A SLOTTED INTAKE. J. Seddon and W. J. G. Trebble. 1954. 18p. diagrs., tab. (ARC R & M 2909; ARC 13,928. Formerly RAE Aero 2409)

The flow into a swept intake at zero forward speed (ground running conditions) is shown to be analogous to the flow round a sharp corner in a duct. Tests have been made on a model of a swept-wing leading-edge intake to measure the losses involved. It is found that the distribution inside the duct can be improved by the use of straight guide vanes, alternatively by means of a special intake slot, or further by a combination of both. Guide vanes increase the mean loss, but the intake slot improves (i.e., reduces) this also. The slot would require to be sealed under flight conditions. It is suggested that this form of slotted intake may have wider applications in the future. Using the results of the experiments and an analogy with the slotted wing, conclusions are drawn regarding the main points of design of the intake slot.

A THEORETICAL EXPRESSION FOR POINT-SOURCE DIFFUSION IN TURBULENT FLOW. A. B. P. Beeton. March 1954. 18p. diagrs. (NGTE R. 152)

A general expression governing the turbulent diffusion of fuel from a point source in a uniform stream is established from theoretical considerations. The distribution at points some distance downstream of the source can then be reduced to a relatively simple equation, which is identical in form with the relation found to hold experimentally for any one section normal to the flow. It indicates a slight modification to the normal empirical law relating distributions at different sections, again confirming the results of experimental work. The general expression enables distributions to be predicted for points as close to the source as may be desired. In comparison with the accurate values obtained by graphical integration of this expression, the approximate equation is found to give better than 1 percent accuracy at all points beyond about 5 mixing lengths downstream of the source.

FREQUENCY TRIPLING OF AN ELECTRIC SUPPLY BY SATURABLE TRANSFORMER AND TRANSDUCTOR TECHNIQUES. F. D. Gill. March 1954. 52p. diagrs., photos., 2 tabs. (RAE Tech. Note EL. 62)

Known methods of frequency tripling by means of saturable transformers are examined and found to be too sensitive to input voltage variations for some purposes. A transductor technique has been developed which will tolerate substantial input voltage variations (8 percent). The method is sensitive to the value of load impedance, which must be kept reasonably constant. The frequency tripler is found to be suitable as a power supply to a magnetic amplifier. Both the weight and response time of the magnetic amplifier, redesigned for the triple frequency,

are reduced. In a typical example it is shown that the reduction in amplifier weight compensates for the weight of the frequency tripler and the additional power requirements. The principal advantage of the technique is the improvement in amplifier response time by a factor of three.

A CUP-TYPE TRANSMITTING ANEMOMETER WITH IMPROVED RESPONSE TO DECREASING GUSTS. W. J. G. Cox. July 1954. 28p. diagrs., photo. (RAE Tech.Note Instn. 140)

A cup-type anemometer is described, capable of giving remote indication and recording of air speed. The instrument is self-generating, giving a voltage output which is reasonably proportional to air speed. A damping brake is described which automatically comes into operation only while the speed is decaying, thereby minimizing the inherent free wheel tendency of this type of instrument and improving its follow-up characteristic to winds of decreasing velocity. The transient responses of the braked and free rotor to step function air velocity changes are deduced, and calibration and loading curves for a particular model are given.

DEVELOPMENT OF A VERY QUICK ACTING ELECTRO HYDRAULIC VALVE. F. W. Read. June 1954. 12p. diagrs., photo. (RAE Tech.Note IAP 1030)

A quick acting hydraulic "on-off" valve was required by Aero Department, R.A.E. as part of experimental equipment to limit the stresses in the tail structure of an aircraft fitted with a powered elevator control and a "g" restrictor. In the first place a "Dowty" type valve was modified and an "on-off" cycle was completed in 45 milliseconds at 700 psi. Flight trials, however, indicated that a shorter operating time was necessary and this note describes a new design in which full hydraulic pressure operates the valves to both "close" and "open" position. A notable improvement in operating times, in rig tests at 450 psi, was shown by the valve "closing" or "opening" in 6 to 7 milliseconds.

INTENSITY/TIME CHARACTERISTICS OF THREE EMITTED WAVEBANDS IN A CAPACITOR DISCHARGE THROUGH XENON. R. L. Aspden. May 1954. 10p. diagrs., photos. (RAE Tech.Note Instn.139)

Intensity/time oscillograms, recording the luminous emission obtained when a capacitor is discharged through gas or vapor, conceal any time factor which may be related to specific frequencies or wavebands. The preliminary investigation described herein shows that in the case of a low pressure xenon filled tube, flashed at normal loading, both the time to peak intensity and the pulse duration are functions of frequency. Although the light is a source of continuously varying spectral quality the composite nature of the flash suggests that for a very limited period during discharge the emission may approach blackbody radiation. A method whereby this period may be located and used to obtain the optimum reproduction in color of a high speed transient is outlined. Details are given of the equipment used in the present tests, together with intensity/time curves of three recorded wavebands covering the visible spectrum.

THE RAPID, ACCURATE PREDICTION OF PRESSURE ON NON-LIFTING OGIVAL HEADS OF ARBITRARY SHAPE, AT SUPERSONIC SPEEDS. B. W. Bolton-Shaw and H. K. Zienkiewicz, English Electric Co., Luton. 1954. 58p. diagrs., 3 tabs. (ARC CP 154)

Five methods are developed for determining the pressure distribution on an arbitrary, pointed, convex axisymmetric head shape, of which the ordinate and its first three derivatives are everywhere continuous. When the geometric details are specified, the time required to pressure plot a head shape is from 20 minutes to 3 hours. The methods were checked in five trial cases against accurate pressure distribution, obtained by using van Dyke's second order theory, and generally gave very good agreement. The best method to use of the five depends upon head shape and on the speed and accuracy required.

THE THERMODYNAMICS OF FRICTIONAL RESISTED ADIABATIC FLOW OF GASES THROUGH DUCTS OF CONSTANT AND VARYING CROSS SECTION. W. R. Thomson. 1954. 44p. diagrs. (ARC CP 158)

This report presents an analytical study dealing with the adiabatic flow of gases with frictional losses through ducts of constant and varying cross section. The thermodynamic treatment is along lines published by other workers such as Bailey and Fabri and is essentially one dimensional in character insofar that frictional effects are assumed to be uniformly distributed over the total cross sectional area of flow. With this simplifying assumption, relationships are deduced connecting the pressure, temperature, velocity, and flow area of the gas at any one plane with those at any other plane in a duct.

AN INVESTIGATION INTO THE ROLLING POWER AND AILERON REVERSAL CHARACTERISTICS OF SWEPT WINGS. A. V. Coles and R. J. Margetts. 1954. 28p. diagrs., photo., 3 tabs. (ARC CP 159)

This paper reviews briefly existing theories relating to swept wings and presents the results obtained from a program of tests on flexible swept wings. The wings tested were of constant span, aspect ratio and area and had angles of sweep ranging from 15° sweepforward to 60° sweepback. The tests were carried out in a low-speed wind-tunnel, compressibility effects being absent. The test results showed that the reversal speeds of wings of the same stiffness increase with both sweepback and sweepforward, the minimum value occurring with a small amount of sweepback. Predictions of reversal speeds based on semirigid theory showed good agreement with experimental results.

THE PERFORMANCE OF A MULTI-ENGINE HELICOPTER FOLLOWING FAILURE OF ONE ENGINE DURING TAKE-OFF OR LANDING. A. L. Oliver. 1954. 15p. diagrs., tab. (ARC CP 175)

A theoretical analysis has been made considering the type of site proposed for civil operation in built-up areas. The performance of a twin engine helicopter similar to the Bristol 173 appears to be adequate for safe operation, but the handling judgment involved in return landings may make the performance difficult to achieve. A take-off technique allowing climb-away after engine failure at any stage is preferable but this is not possible for the twin engine machine within the space available. It is possible if the twin engines are replaced by four of the same effective total power but only if the turning climb-away is made after engine failure. A helicopter with sufficient performance for a straight climb-away can in general hover with one engine inoperative.

AERODYNAMIC DERIVATIVES FOR A DELTA WING OSCILLATING IN ELASTIC MODES. D. L. Woodcock. 1954. 33p. diagrs., 13 tabs. (ARC CP 170)

Aerodynamic derivatives are given for a delta wing of aspect ratio 3 and 90° apex angle oscillating with symmetric elastic modes in incompressible inviscid flow. They have been determined by the lattice method of W. P. Jones, using the values of the downwash calculated by D. E. Lehrian when obtaining aerodynamic derivatives for the same delta wing oscillating in rigid wing modes. Results for several modes are given both as local derivatives and also as equivalent constant derivatives. Derivatives for other modes can be obtained either from these or from the values of the reciprocal of the downwash matrix, which also are tabulated.

Advisory Group for Aeronautical Research and Development. THE MECHANISM OF CARBON FORMATION. George Porter. (Scheveningen Netherlands Conference - May 3-7, 1954). 16p. diagrs. (AG13/M9)

This paper gives a more detailed account of the theory of carbon formation in combustion processes which has been briefly stated elsewhere. Other theories are critically reviewed and a summary is given of the experimental data relating to carbon formation which has been obtained by the flash photolysis technique. The mechanism proposed, which is believed to apply to the high temperature pyrolysis of hydrocarbons as well as to diffusion flames, premixed flames, and explosions in closed vessels, is as follows: all hydrocarbons, when pyrolysed under the high temperature conditions prevalent in the above systems, undergo a decomposition which results eventually in the formation of acetylene and hydrogen. Acetylene then forms carbon particles by a simultaneous condensation and dehydrogenation.

ON EXACT SOLUTIONS OF THE STOKES-NAVIER EQUATIONS OF INCOMPRESSIBLE FLUIDS AT MODIFIED BOUNDARY CONDITIONS. (Über exakte Lösungen der Stokes-Navier-Gleichungen inkompressibler Flussigkeiten bei veränderten Grenzbedingungen). Jakob Ackeret. September 1954. 20p. diagrs. (Trans. from Zeitschrift für angewandte Mathematik und Physik, v. 3, no. 4, 1952, p. 259-271)

There exist solutions of the hydrodynamic equations if the boundary conditions are modified. If it can be arranged that the "solid" boundaries are actually moving with the fluid velocity then really simple solutions are obtained. Several examples are worked out. As turbulence is unlikely to occur under these conditions, the power to move bodies in a viscous fluid at high Reynolds numbers would become extremely low. It seems that even a partial fulfilment of these changed conditions would be of practical interest.

NACA Rept. 1145

A METHOD OF CALIBRATING AIRSPEED INSTALLATIONS ON AIRPLANES AT TRANSONIC AND SUPERSONIC SPEEDS BY THE USE OF ACCELEROMETER AND ATTITUDE-ANGLE MEASUREMENTS. John A. Zalovcik, Lindsay J. Lina and James P. Trant, Jr. 1953. ii, 13p. diagrs., photos., tab. (NACA Rept. 1145. Formerly TN 2099; TN 2570)

A method is described for calibrating airspeed installations on airplanes at transonic and supersonic speeds in which use is made of normal and longitudinal accelerations and attitude angle as measured by instruments carried within the airplane. An airspeed calibration of the pitot-static installation on a jet fighter airplane is presented as an experimental check on the accuracy of the method.

NACA Rept. 1160

THE ZERO-LIFT DRAG OF A SLENDER BODY OF REVOLUTION (NACA RM-10 RESEARCH MODEL) AS DETERMINED FROM TESTS IN SEVERAL WIND TUNNELS AND IN FLIGHT AT SUPERSONIC SPEEDS. Albert J. Evans. 1954. ii, 13p. diagrs., tab. (NACA Rept. 1160. Formerly TN 2944)

Presents zero-lift drag data of an NACA RM-10 slender body of revolution with and without stabilizing fins attached. The results from several wind tunnels and in flight are compared. The results cover a Reynolds number range from about 1×10^6 to 40×10^6 for the wind-tunnel models and 12×10^6 to 140×10^6 for the flight models. The Mach numbers covered include 1.5 to 2.4 in the wind tunnels and 0.85 to 2.5 in flight.

NACA RM 54F22

EFFECTS OF MULTIAXIAL STRETCHING ON CRAZING AND OTHER PROPERTIES OF TRANSPARENT PLASTICS. Irvin Wolock and Desmond A. George, National Bureau of Standards. October 1954. 34p. diagrs., photos., 10 tabs. (NACA RM 54F22)

An investigation was made of the effects of orientation by multiaxial stretching on properties of various plastic glazing materials. The materials studied were Lucite HC-222 (polymethyl methacrylate), Plexiglas 55 (modified polymethyl methacrylate), Gafite, and resin C (polymethyl alpha-chloroacrylate). The following tests were conducted on samples of these materials stretched up to 150 percent: Dimensional stability at elevated temperatures, surface abrasion, standard tensile tests, and stress-solvent crazing tests using ethylene dichloride.

NACA RM E54H04

SLOWING-DOWN DISTRIBUTION TO INDIUM RESONANCE OF NEUTRONS FROM A Ra-α-Be SOURCE IN WATER-IRON MIXTURES. Daniel Fieno. November 1954. 16p. diagrs., photo., 2 tabs. (NACA RM E54H04)

The mean square slowing-down distance to indium resonance $\overline{r^2}$ derived from the slowing-down distribution has been measured for water and for three water-iron mixtures for neutrons from a 0.1-gram Ra-α-Be source. The values of $\overline{r^2}$ for water-iron volume ratios of 1, 2, and 3 and for water were 347, 336, 314, and 291 centimeters squared, respectively. Within the accuracy of the measurements, the relaxation length λ was approximately the same for water and for the three water-iron mixtures, the average value being 10.0 centimeters.

NACA TN 3152

TRANSVERSE OSCILLATIONS IN A CYLINDRICAL COMBUSTION CHAMBER. Franklin K. Moore and Stephen H. Maslen. October 1954. 25p. diagrs. (NACA TN 3152)

Transverse oscillations in combustion chambers are studied. With an axial temperature gradient considered, the modes of weak oscillation are described for low Mach number. Amplification by coupling with vigorous combustion in the flame-holder wake is assumed. The amplification depends on flame-holder and centerbody diameters and on time-lag effects. The nature of finite transverse periodic waves is also analyzed. Results show that such waves have frequencies independent of amplitude and do not steepen with time.

NACA TN 3302

LIQUEFACTION OF AIR IN THE LANGLEY 11-INCH HYPERSONIC TUNNEL. Charles H. McLellan and Thomas W. Williams. October 1954. 36p. diagrs., 4 tabs. (NACA TN 3302)

Pressure and scattered-light measurements were made in the Langley 11-inch hypersonic tunnel to determine the effect of stagnation temperature on the flow in two Mach number 7 nozzles and to determine the nature of the condensation process occurring at low stagnation temperatures. Liquefaction of the air occurred very close to the saturation point without a condensation shock. This result indicates that liquefaction took place on foreign nuclei such as water and carbon-dioxide particles. The results from varying the water vapor and carbon-dioxide content, however, could not be correlated with Max Volmer's condensation theory. The average particle radius was 480 angstroms in the test section of the

single-step Mach number 7 nozzle for stagnation conditions of about 530° R and 29 atmospheres. Under the same conditions about 10^{10} particles per cubic centimeter were present.

NACA TN 3342

EXPERIMENTAL DETERMINATION OF BOUNDARY-LAYER TRANSITION ON A BODY OF REVOLUTION AT M = 3.5. James R. Jedlicka, Max E. Wilkins and Alvin Seiff. October 1954. 56p. diagrs., photos. (NACA TN 3342. Formerly RM A53L18)

Boundary-layer-transition tests were made in free flight through still air on a small-scale fin-stabilized body of revolution of fineness ratio 30 at a Mach number of 3.5 and length Reynolds numbers of 12 and 24 million. Three types of surfaces were tested and the transition Reynolds number was found to depend critically on the surface smoothness. Angle of attack was found to influence transition strongly. This effect was correlated in terms of pressure rise along streamlines and led to a prediction of the effect of varying the body shape on sheltered-side transition. In general, the transition points were time dependent, fluctuating in one case over a range of Reynolds numbers from 4 to 20 million. Steady laminar flow was observed to a length Reynolds number of 11 million. Transition due to roughness and adverse pressure gradient occurred even though the tests were within the region of theoretical infinite laminar stability to small disturbances.

Aeronautical Research Council (Gt. Brit.)
THE HIGH-SPEED LABORATORY OF THE AERODYNAMICS DIVISION, N. P. L. D. W. Holder. 1954. 277p. diagrs., photos., 2 tabs. (ARC R & M 2560)

The high-speed tunnel installation of the Aerodynamics Division of the National Physical Laboratory is described. The installation consists of the 12-in. diameter high-speed tunnel, the 20- by 8-in. high-speed tunnel, and a number of smaller tunnels all of which are operated on the induction principle from a common compressed-air storage capacity. The new 18- by 14-in. high-speed tunnel is also described. Some of the experimental techniques which have been used are described, including the schlieren and shadowgraph methods. The last of the report reviews the experimental results obtained in the high-speed tunnels during and immediately before the war. The phenomena which occur on a particular airfoil as Mach is increased are described and the effect of airfoil shape discussed.

THE DRAG INCREASE AT HIGH SUBSONIC SPEEDS. K. Oswatitsch. 1954. 16p. diagrs. (ARC R & M 2716; ARC 11,246. Formerly RAE Tech. Note Aero 1919)

The drag increase beyond the critical Mach number is calculated by modifying the supersonic part of the Karman-Tsien pressure distribution on a profile. This is possible when the supersonic regions are not too large. The formula giving the modified pressure distribution is derived very roughly. It may give only one of the main effects appearing when supersonic speeds occur in the flow, and may be changed and calculated more exactly later. For the calculation of the drag increase, the formula is sufficient. Within the approximation of the theory the lift coefficient is practically unchanged.

A SIMPLE METHOD OF COMPUTING C_D FROM WAKE TRAVERSES AT HIGH-SUBSONIC SPEEDS. J. S. Thompson. 1954. 12p. diagrs., 4 tabs. (ARC R & M 2914; ARC 8462. Formerly RAE Aero 2005)

This note gives a convenient method of obtaining C_D from a pitot-static traverse in an airfoil wake, using Jones' modified equation for compressible flow. Charts are provided from which the integrand C_D' can easily be obtained for any point in the traverse, but it is shown that in nearly all cases an accuracy of 1 percent in C_D can be obtained by applying an integrating factor to the area under the total-head loss curve. Three appendices give (a) a summary of the standard theory and equations, (b) details of the construction of the charts, and (c) an empirical equation giving C_D' in a simple analytical form.

NOTE ON THE DYNAMIC CHARACTERISTICS OF SERVO-TAB SYSTEMS OF CONTROL. D. Adamson and D. J. Lyons. 1954. 12p. diagrs., tab. (ARC R & M 2853; ARC 11,666. Formerly RAE Aero 2263)

Curves have been constructed from which estimates can be made of those dynamic characteristics of the servo-tab-type of control which are of chief interest to the designer; namely, the magnitude of the first overshoot of the main flying control beyond its equilibrium position, the lag of the main control surface behind the tab movement, the damping of the main control surface oscillation, and the angular velocity possessed by the main control when it first passes through its equilibrium position.

MODEL TESTS OF AN AIR INTERCHANGE SYSTEM FOR REMOVING ENGINE EXHAUST PRODUCTS FROM A WIND TUNNEL. K. W. Newby, E. G. Barnes and D. W. Bottle. 1954. 32p. diagrs., 3 tabs. (ARC R & M 2639; ARC 11,604. Formerly RAE Aero 2249)

An investigation has been made on the functioning of an air interchange system for removing from a return-circuit wind tunnel a high proportion of the exhaust products from propulsive units under test.

The tests were planned to assist the design of an engine altitude tunnel. The system tested was generally very satisfactory for the specified requirements, and can operate up to interchange ratios of the order of 15 percent without interfering appreciably with the flow in the tunnel working section.

FLIGHT-TEST MEASUREMENTS OF AILERON CONTROL SURFACE BEHAVIOUR AT SUPERCRITICAL MACH NUMBERS. Harvey H. Brown, George A. Rathert, Jr. and Lawrence A. Clousing. April 23, 1947. 26p. diagrs., photos., 2 tabs. (NACA RM A7A15) (Declassified from Confidential, 10/12/54)

The behavior at supercritical Mach numbers of the ailerons of a jet-propelled fighter has been measured up to 0.866 Mach number. The considerable amount of aileron upfloat occurring at these Mach numbers was found to be due to a large loss in pressure recovery on the upper surface aft of the shock wave which caused very large increases in the aileron hinge moments. Data obtained from pressure distribution measurements are presented to show the very critical effect of Mach number on the magnitude of these hinge moments.

✓ NACA RM A7G03

AN ANALYSIS OF LONGITUDINAL-CONTROL PROBLEMS ENCOUNTERED IN FLIGHT AT TRANSONIC SPEEDS WITH A JET-PROPELLED AIRPLANE. Harvey H. Brown, L. Stewart Rolls and Lawrence A. Clousing. September 25, 1947. 56p. diagrs., photos., 3 tabs. (NACA RM A7G03) (Declassified from Confidential, 10/12/54)

During flight tests of a jet-propelled airplane, a sudden pitch-up motion of the airplane occurred in a recovery from a high-speed dive, although the pilot had not moved the controls so as to produce this motion. Measurements of the stability and control characteristics of the airplane and of the wing pressure distribution during the dive and recovery are presented.

✓ NACA RM A7I16

HIGH-SPEED WIND-TUNNEL TESTS OF A MODEL PURSUIT AIRPLANE AND CORRELATION WITH FLIGHT-TEST RESULTS. Joseph W. Cleary and Lyle J. Gray. January 21, 1948. 56p. diagrs., photos. (NACA RM A7I16) (Declassified from Confidential, 10/12/54)

A wind-tunnel investigation of the aerodynamic characteristics of a 1/3-scale model of a jet propelled airplane was made at high subsonic Mach numbers for comparison with flight test results. Tests were made of wing and fuselage dive-recovery flaps to determine their effectiveness at high speed. In general, the wind-tunnel results show good agreement with the flight-test data. Both wing and fuselage dive-recovery flaps were effective for increasing longitudinal control. However, the wing dive-recovery flaps lost their effectiveness at high Mach numbers.

✓ NACA RM A51E04

EXPERIMENTAL STUDY OF THE EFFECT OF SWEEPBACK ON TRANSONIC AILERON FLUTTER. Lionel L. Levy, Jr. and Earl D. Knechtel. September 1951. 20p. diagrs., photo. (NACA RM A51E04) (Declassified from Confidential, 10/12/54)

The effect of sweepback on the Mach number for which transonic aileron flutter occurs was determined for a wing-aileron combination with an NACA 65-213, a = 0.5, airfoil section. The Mach number range of the investigation extended from 0.70 to 0.95 approximately and the Reynolds number was about 1 million. Angle of attack was varied from -6° to $+6^{\circ}$ for sweep angles of 0° to 50°.

NACA RM A51G10

PRELIMINARY INVESTIGATION OF THE PRESSURE FLUCTUATIONS IN THE WAKES OF TWO-DIMENSIONAL WINGS AT LOW ANGLES OF ATTACK. Robert M. Sorenson, John A. Wyss and James C. Kyle. October 1951. 58p. diagrs., photos. (NACA RM A51G10) (Declassified from Confidential, 10/12/54)

An experimental investigation has been conducted to obtain fundamental two-dimensional data on the extent, magnitude, and other characteristics of the

pressure fluctuations behind airfoils with NACA 23013 and NACA 651-213 sections. Results are presented for the airfoil with the NACA 23013 section through a range of Mach numbers from 0.60 to 0.80 and through a range of angles of attack of -2° to $+5^{\circ}$. The report discusses methods of defining wing- and tail-buffet boundaries in terms of pressure fluctuations in the wake.

NACA RM A51H15

LOAD DISTRIBUTION OVER A FUSELAGE IN COMBINATION WITH A SWEPT WING AT SMALL ANGLES OF ATTACK AND TRANSONIC SPEEDS. Maurice D. White and Bonne C. Look. November 1951. 26p. diagrs., photo., tab. (NACA RM A51H15) (Declassified from Confidential, 10/12/54)

Free-fall tests were made at Mach numbers from 0.85 to 1.06 of a wing-body configuration having a 45° sweptback cambered and twisted wing of aspect ratio 6 on a fuselage of fineness ratio 12.4. The distributions of load over the fuselage as determined from surface pressure measurements are shown in relation to the lifts of the wing for small angles of attack. Comparisons are made with wind-tunnel load distributions and with theoretical load distributions for subsonic and supersonic speeds.

NACA RM A51I25

AN ANALYSIS OF THE EFFECT OF STRUCTURAL FEEDBACK ON THE FLUTTER OF A CONTROL SURFACE HAVING POWER-BOOST SYSTEM. Robert H. Barnes. June 1952. 29p. diagrs., photos. (NACA RM A51I25) (Declassified from Confidential, 10/12/54)

A wind-tunnel program was conducted to determine the cause of flutter which had been experienced on an airplane which employed a full power-boost system. Analysis of the data showed that the power-boost control valve was being actuated due to structural deformation. Accordingly, an analytical study was conducted which showed that structural feedback could have been the cause of flutter.

NACA RM A51K27

BODIES OF REVOLUTION FOR MINIMUM DRAG AT HIGH SUPERSONIC AIRSPEEDS. A. J. Eggers, Jr., David H. Dennis and Meyer M. Resnikoff. February 1952. 44p. diagrs., photos. (NACA RM A51K27) (Declassified from Confidential, 10/12/54)

Newtonian impact theory is used to determine body shapes of minimum drag under various combinations of the conditions of given body length, base diameter, surface area, and volume. In addition an estimate is made of centrifugal forces, and their effect on one minimum-drag shape is considered. An experimental investigation carried out in the Ames 10- by 14-inch supersonic wind tunnel on a family of bodies, including two of the minimum-drag shapes, is found to provide a substantiation of the analysis.

NACA RM A51L03a

SOME EFFECTS OF SIDE-WALL MODIFICATIONS ON THE DRAG AND PRESSURE RECOVERY OF AN NACA SUBMERGED INLET AT TRANSONIC SPEEDS. Robert A. Taylor. February 1952. 25p. diagrs., photos. (NACA RM A51L03a. (Declassified from Confidential, 10/12/54)

Comparative data were obtained for an NACA submerged inlet and two ramp-wall modifications of the NACA submerged inlet. These modified inlets were generally superior to the NACA inlet from the standpoint of pressure recovery at the highest test mass-flow ratios. No significant changes in drag were produced by the modification for Mach numbers below 1.0 and for a mass-flow ratio of 0.88, but small increases in drag, at supersonic Mach numbers and the higher angles of attack, resulted from the modifications.

NACA RM A51L17b

A CORRELATION BY MEANS OF THE TRANSONIC SIMILARITY RULES OF THE EXPERIMENTALLY DETERMINED CHARACTERISTICS OF 22 RECTANGULAR WINGS OF SYMMETRICAL PROFILE. John B. McDevitt. February 1952. 60p. diagrs., 3 tabs. (NACA RM A51L17b) (Declassified from Confidential, 10/12/54)

The similarity rules have been used to correlate the experimental data for a series of 22 rectangular, symmetrical wings having NACA 63A0XX sections, aspect ratios from 1/2 to 6, and thicknesses from 2 to 10 percent. The data were obtained by use of the transonic bump technique over a Mach number range of 0.40 to 1.10, corresponding to a Reynolds number range from 1.25 to 2.05 million.

NACA RM A52A29

FLIGHT TESTING BY RADIO REMOTE CONTROL - FLIGHT EVALUATION OF A BEEP-CONTROL SYSTEM. Howard L. Turner, John S. White and Rudolph D. Van Dyke, Jr. April 1952. 55p. diagrs., photos., tab. (NACA RM A52A29) (Declassified from Confidential, 10/12/54)

A comparison between manual control and remote control showed that a beep-type, ratio-remote-control system was, in general, a satisfactory means of control for conducting standard handling-quality flight tests. The dynamic characteristics of the airplane-autopilot combination and the selection of the proper parameter adjustments are discussed.

NACA RM A52B05

FULL-SCALE WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF WING MODIFICATIONS AND HORIZONTAL-TAIL LOCATION ON THE LOW-SPEED STATIC LONGITUDINAL CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE. Ralph L. Maki. April 1952. 54p. diagrs., photos., 7 tabs. (NACA RM A52B05) (Declassified from Confidential, 10/12/54)

Low-speed lift, drag, and pitching-moment characteristics of a full-scale 35° swept-wing airplane are presented for Reynolds numbers ranging from 3.2×10^6 to 12.3×10^6, and with the horizontal tail on and off and at a lowered position. Similar data are given for the airplane with modified wing leading edges. Selected tuft photographs are given for several configurations.

NACA RM A52B13

THE EFFECT OF BLUNTNESS ON THE DRAG OF SPHERICAL-TIPPED TRUNCATED CONES OF FINENESS RATIO 3 AT MACH NUMBERS 1.2 TO 7.4. Simon C. Sommer and James A. Stark. April 1952. 18p. photos., diagrs. (NACA RM A52B13) (Declassified from Confidential, 10/12/54)

The drag of spherically blunted conical models of fineness ratio 3 was investigated in the Ames supersonic free-flight wind tunnel at Mach numbers from 1.2 to 7.4 in the Reynolds number range from 1.0×10^6 to 7.5×10^6. The models tested had bluntness ratios of nose diameter to base diameter from 0 to 0.50. The use of small amounts of bluntness for minimizing drag and the drag penalties associated with large bluntnesses are discussed.

NACA RM A52C20

DRAG OF CIRCULAR CYLINDERS FOR A WIDE RANGE OF REYNOLDS NUMBERS AND MACH NUMBERS. Forrest E. Gowen and Edward W. Perkins. June 1952. 26p. diagrs., photos. (NACA RM A52C20) (Declassified from Confidential, 10/12/54)

Pressure distribution measurements on a two dimensional circular cylinder have been made at high subsonic and supersonic speeds. Drag coefficients obtained from these measurements are presented with results from other sources. It was found that a maximum drag coefficient of about 2.1 occurs near sonic velocity. As the Mach number was increased to 2.9 the drag coefficient decreased to about 1.34. No effects of Reynolds number were found at supercritical Mach numbers. Effects of fineness ratio on drag of three-dimensional cylinders at supersonic speeds were investigated and found to be small.

NACA RM A52C24

INVESTIGATION OF LIFT AND CENTER OF PRESSURE OF LOW-ASPECT-RATIO, CRUCIFORM, TRIANGULAR, AND RECTANGULAR WINGS IN COMBINATION WITH A SLENDER FUSELAGE AT HIGH SUPERSONIC SPEEDS. Thomas N. Canning and Billy Pat Denardo. June 1952. 28p. diagrs., photos. (NACA RM A52C24) (Declassified from Confidential, 10/12/54)

Low-aspect-ratio triangular and rectangular wings in combination with a slender body have been tested in the Mach number range between 1.3 and 6.2 and Reynolds numbers based on body length from 2.8 to 16 million in the Ames supersonic free-flight wind tunnel. The experimental lift-curve slope and center of pressure positions are compared with theoretical predictions. Drag of the configurations is also presented. The possible lift-drag ratios for the configurations tested are estimated for Mach number 6.0 flight.

NACA RM A52D01a

EFFECTS OF PROPELLER-SPINNER JUNCTURE ON THE PRESSURE-RECOVERY CHARACTERISTICS OF AN NACA 1-SERIES D-TYPE COWL IN COMBINATION WITH A FOUR-BLADE SINGLE-ROTATION PROPELLER AT MACH NUMBERS UP TO 0.83 AND AT AN ANGLE OF ATTACK OF 0°. Robert I. Sammonds and Ashley J. Molk. June 1952. 45p. diagrs., photos., tab. (NACA RM A52D01a) (Declassified from Confidential, 10/12/54)

Measurement of ram-recovery ratio was made in the duct of a cowling-spinner combination. Tests were conducted at Mach numbers from 0.20 to 0.83 with the propeller operating with an "ideal" propeller-spinner juncture (propeller blade extended to spinner surface) and a platform juncture (fixed airfoil-shaped land that permitted blade angle change), and with the propeller removed. Tests were run at propeller blade angles of 60°, 50°, and 40°, for propeller advance-diameter ratios from 1.3 to 4.5 and inlet-velocity ratios from 0.26 to 1.33. All of the tests were conducted at an angle of attack of 0° and a Reynolds number of 1.77 million, based on the maximum diameter of the cowl.

NACA RM A52D11

THE TRANSONIC CHARACTERISTICS OF 38 CAMBERED RECTANGULAR WINGS OF VARYING ASPECT RATIO AND THICKNESS AS DETERMINED BY THE TRANSONIC-BUMP TECHNIQUE. Warren H. Nelson and Walter J. Krumm. July 1952. 173p. diagrs., photos. (NACA RM A52D11) (Declassified from Confidential, 10/12/54)

An investigation was made in the Ames 16-foot high-speed wind tunnel utilizing the transonic-bump technique to determine the aerodynamic characteristics at transonic Mach numbers of 38 cambered rectangular wings. The wings had aspect ratios of 4, 3, 2, 1.5, and 1, and NACA 63A2XX and 63A4XX sections with thickness-to-chord ratios of 10, 8, 6, 4, and 2 percent. The Mach number range was 0.6 to 1.12 with corresponding Reynolds numbers of 1.7 to 2.2 million. The data are presented without analysis.

NACA RM A52D17

EFFECT OF TRAILING-EDGE THICKNESS ON LIFT AT SUPERSONIC VELOCITIES. Dean R. Chapman and Robert H. Kester. July 1952. 24p. diagrs., photos. (NACA RM A52D17) (Declassified from Confidential, 10/12/54)

Lift forces on various rectangular-plan-form wings were measured in the Mach number range between 1.5 and 3.1 at Reynolds numbers between 0.55 and 2.2 million. The wings differed in trailing-edge thickness, profile shape, maximum thickness ratio, and aspect ratio. Measurements were made on wings with and without a boundary-layer trip and are compared to theoretical calculations. Calculated results using shock-expansion theory are presented for Mach numbers up to 10. In general, thickening the trailing edge resulted in an increase in lift-curve slope. This increase varied between a few percent and about 15 percent, depending primarily on the trailing-edge thickness. Calculations indicate that somewhat greater increases are possible at high supersonic Mach numbers.

NACA RM A52D24

SUPPLEMENTARY NOTE ON MODIFIED-IMPACT-THEORY CALCULATIONS FOR BODIES OF REVOLUTION HAVING MINIMUM DRAG AT HYPERSONIC SPEEDS. Meyer M. Resnikoff. July 1952. 13p. diagr. (NACA RM A52D24) (Declassified from Confidential, 10/12/54)

Newtonian impact theory as modified in NACA RM A51K27, 1952, to include an estimate of centrifugal forces is used to determine bodies for hypersonic flight having minimum pressure foredrag under various combinations of the conditions of given body length, diameter, volume, and surface area.

NACA RM A52E20

AN EXPERIMENTAL INVESTIGATION OF THE BASE PRESSURE CHARACTERISTICS OF NONLIFTING BODIES OF REVOLUTION AT MACH NUMBERS FROM 2.73 TO 4.98. John O. Reller, Jr. and Frank M. Hamaker. September 1952. 47p. diagrs., photos. (NACA RM A52E20) (Declassified from Confidential, 10/12/54)

Base pressure characteristics of related nonlifting bodies of revolution were investigated at free-stream Mach numbers from 2.73 to 4.98 and Reynolds numbers from 0.6×10^6 to 8.8×10^6. The basic body shape was a 10-caliber tangent ogive with a cylindrical afterbody. The variation of base pressure coefficient with free-stream Mach number and Reynolds number was determined for laminar-, transitional-, and turbulent-boundary-layer flow. Some effects of body fineness ratio, nose-profile shape, and afterbody shape (boattail) were also included in the investigation.

NACA RM A52F13

CONTROL EFFECTIVENESS AND HINGE-MOMENT CHARACTERISTICS AT LOW SPEED OF LARGE-CHORD, HORN-BALANCED, FLAP-TYPE CONTROLS ON A TRIANGULAR WING OF ASPECT RATIO 2. Jules B. Dods, Jr. August 1952. 53p. diagrs., photos., 2 tabs. (NACA RM A52F13) (Declassified from Confidential, 10/12/54)

The low-speed lift and hinge-moment characteristics are presented for a triangular wing of aspect ratio 2 having large-chord flap-type controls with a swept-back hinge line and with various sizes and shapes of horn balances. The effects of changes in the following were examined: shielding of the horn balance, percentage of horn balance, trailing-edge thickness, flap nose seal, contour of the horn balance, and Reynolds number. One of the controls which had a nearly optimum balance at low speed was compared with several other types of controls on triangular wings and with an all-movable triangular-wing control.

NACA RM A52F17

INVESTIGATION OF AN NACA SUBMERGED INLET AT MACH NUMBERS FROM 1.17 to 1.99. Warren E. Anderson and Alson C. Frazer. September 1952. 29p. diagrs., photo. (NACA RM A52F17) (Declassified from Confidential, 10/12/54)

An investigation was conducted with a small-scale NACA submerged inlet at supersonic Mach numbers from 1.17 to 1.99. The measured performance of a submerged inlet at low supersonic Mach numbers was compared to the calculated performance of a normal-shock scoop inlet on the basis of net thrust coefficients.

NACA RM A52I17

LATERAL AND DIRECTIONAL DYNAMIC-RESPONSE CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE AS DETERMINED FROM FLIGHT MEASUREMENTS. William C. Triplett and Stuart C. Brown. December 1952. 62p. diagrs., photo., 3 tabs. (NACA RM A52I17) (Declassified) from Confidential, 10/12/54)

Lateral and directional dynamic-response characteristics, including frequency responses, transfer functions, and stability derivatives of a 35° swept-wing fighter airplane are obtained from flight measurements of transient responses to rudder and to aileron control deflections. Flight records were obtained at two altitudes between Mach numbers of 0.50 and 1.04. Effects of aeroelasticity are discussed, and test results are compared to predictions based on wind-tunnel and theoretical studies.

NACA RM A53G31

A CORRELATION BY MEANS OF TRANSONIC SIMILARITY RULES OF THE EXPERIMENTALLY DETERMINED CHARACTERISTICS OF 18 CAMBERED WINGS OF RECTANGULAR PLAN FORM. John B. McDevitt. September 1953. 57p. diagrs. (NACA RM A53G31) (Declassified from Confidential, 10/12/54)

The effects of one type of camber on the aerodynamic characteristics of rectangular wing at high subsonic and transonic speeds have been studied by applying the transonic similarity rules to the correlation of experimental data for a series of 18 cambered wings having NACA 63A2XX and 63A4XX sections, aspect ratios from 1 to 4, and thicknesses from 4 to 8 percent. The data were obtained by use of a transonic bump over a Mach number range of 0.6 to 1.1.

NACA RM E51F15

INVESTIGATION OF DYNAMIC CHARACTERISTICS OF A TURBINE-PROPELLER ENGINE. Frank L. Oppenheimer and James R. Jacques. September 1951. 22p. diagrs., tab. (NACA RM E51F15) (Declassified from Confidential, 10/12/54)

Time constants that characterize engine speed response of a turbine-propeller engine over the cruising speed range for various values of constant fuel flow and constant blade angle were obtained both from steady-state characteristics and from transient operation. Magnitude of speed response to changes in fuel flow and blade angle was investigated and is presented in the form of gain factors. Results indicate that at any given value of speed in the engine cruising speed range, time constants obtained both from steady-state characteristics and from transient operation agree satisfactorily for any given constant fuel flow, whereas time constants obtained from

transient operation exceed time constants obtained from steady-stage characteristics by approximately 14 percent for any given blade angle.

NACA RM E51F19

PRELIMINARY INVESTIGATION OF THE CONTROL OF A GAS-TURBINE ENGINE FOR A HELICOPTER. Richard P. Krebs. September 1951. 13p. diagrs. (NACA RM E51F19) (Declassified from Confidential, 10/12/54

An analog investigation of the power plant for a gas-turbine powered helicopter indicates that currently proposed turbine-propeller engine controls are satisfactory for helicopter application. Power increases from one-half to full rated at altitudes from sea level to 15,000 feet could be made in less than 4 seconds with either the rotor or propellers absorbing the engine power.

NACA RM E51J25

EXPERIMENTAL INVESTIGATION OF THE VIBRATION CHARACTERISTICS OF FOUR DESIGNS OF TURBINE BLADES AND OF THE EFFECT PRODUCED BY VARYING THE AXIAL SPACING BETWEEN NOZZLE BLADES AND TURBINE BLADES. W. C. Morgan and C. R. Morse. February 1952. 28p. diagrs., photos., tab. (NACA RM E51J25) (Declassified from Confidential, 10/12/54)

An investigation was made to determine the effects of varying the spacing between the nozzle blades and the turbine blades of a turbo-jet engine on turbine-blade vibration for four turbine-blade designs of different degrees of stiffness. In general, there was a tendency toward increase in occurrence of vibration with decrease in spacing. The effect was most evident in the case of the turbine blades that had greater stiffness.

NACA RM E51K21

A METHOD FOR ESTIMATING SPEED RESPONSE OF GAS-TURBINE ENGINES. Harold Gold and Solomon Rosenzweig. January 1952. 26p. diagrs. (NACA RM E51K21) (Declassified from Confidential, 10/12/54)

A brief method is presented for estimating the speed response of turbojet and turbine-propeller engines to a step change in fuel flow. The method approximates the dynamic equilibrium in the gas-turbine engine with a first-order linear differential equation, the time constant of which varies inversely with the equilibrium speed. The deviation of the calculated values from the mean experimental values is only slightly greater than the spread of experimental data.

NACA RM E52B14

RELATIONS BETWEEN FUEL PROPERTIES AND COMBUSTION CARBON DEPOSITION. Edmund R. Jonash, Jerrold D. Wear and Robert R. Hibbard. April 1952. 67p. diagrs., 3 tabs. (NACA RM E52B14) (Declassified from Confidential, 10/12/54)

Methods for predicting carbon-forming propensity of turbojet-engine fuels from results of simple laboratory tests are discussed with a view toward their application to the control of jet fuel quality. The methods involve the use of aromatic content, hydrogen carbon ratio, distillation temperatures, gravity, aniline point, and several empirical laboratory carbon deposition tests. Most accurate prediction of carbon deposition was obtained with (1) the NACA K factor (function of hydrogen-carbon ratio and volumetric average boiling temperature), and (2) the smoking tendency of the fuel, although this latter method requires additional data to establish reproducibility of the method among laboratories.

NACA RM E52D10

INVESTIGATION OF ENGINE PERFORMANCE AND HIGH-TEMPERATURE PROPERTIES OF PRECISION-CAST TURBINE BLADES OF HIGH-CARBON STELLITE 21 AND CONTROLLED-GRAIN-SIZE STELLITE 21. Charles Yaker, Floyd B. Garrett and Paul F. Sikora. June 1952. 38p. diagrs., photos., 6 tabs. (NACA RM E52D10) (Declassified from Confidential, 10/12/54)

The effect of controlled grain size and increased carbon content on engine performance and high temperature properties of precision-cast Stellite 21 turbine blades was investigated. Blades were cast to result in controlled grain sizes, classed fine, medium, and coarse; others were cast of high-carbon Stellite 21. The blades were operated in a turbojet engine. Laboratory stress-rupture tests of specimens cut from blades were conducted at the stress and temperature encountered during rated-speed engine operation. The results of the engine and laboratory tests indicated that (1) fine-grain Stellite 21 blades had lower life and creep resistance than the medium- and coarse-grain blades, and all three grain size blades showed less scatter than the production blades; and (2) higher-carbon Stellite 21 had higher blade life than the production Stellite.

NACA RM E52L17

BEHAVIOR OF FORGED S-816 TURBINE BLADES IN STEADY-STATE OPERATION OF J33-9 TURBOJET ENGINE WITH STRESS-RUPTURE AND METALLOGRAPHIC EVALUATIONS. F. B. Garrett, C. A. Gyorgak and J. W. Weeton. February 1953. 29p. diagrs., photos., 3 tabs. (NACA RM E52L17) (Declassified from Confidential, 10/12/54)

An investigation was conducted to determine the behavior of recently produced, forged S-816 turbine blades in a full-scale turbojet engine, and in particular, the scatter in performance of the alloy. The turbine blades were operated as continuously as possible at a temperature of 1500° F and a centrifugal stress of 21,500 pounds per square inch. The operating lives of the turbine blades varied from 181 to 539 hours, a range of 358 hours. Stress-rupture properties of specimens cut from blade airfoils also varied considerably, as much as 1257 hours at 20,000 pounds per square inch and 1500° F. Since the variability or scatter of stress-rupture data is greater than that of blade performance, the scatter is probably caused by variations in the properties of the forged blades rather than by variations caused by engine operation or installation of the blades. Metallographic examinations were made to deter-

mine possible causes of the scatter and although numerous differences in microstructures of blades were found, no consistent trendencies were observed and the findings did not permit an explanation of the scatter of blade performance. The results of the metallographic examinations and of the physical tests indirectly indicated variables in the fabricating method caused the scatter in properties.

NACA RM E52L30

ADHESIVE AND PROTECTIVE CHARACTERISTICS OF CERAMIC COATING A-417 AND ITS EFFECT ON ENGINE LIFE OF FORGED REFRACTALOY-26 (AMS 5760) AND CAST STELLITE 21 (AMS 5385) TURBINE BLADES. Floyd B. Garrett and Charles A. Gyorgak. February 1953. 21p. photos., diagr., 4 tabs. (NACA RM E52L30) (Declassified from Confidential, 10/12/54)

The adhesive and protective characteristics of National Bureau of Standards Coating A-417 were investigated, as well as the effect of the coating on the life of forged Refractaloy 26 and cast Stellite 21 turbine blades. Coated and uncoated blades were run in a full-scale J33-9 engine and were subjected to simulated service operations consisting of consecutive 20-minute cycles (15 min at rated speed and approximately 5 min at idle). The ceramic coating adhered well to Refractaloy 26 and Stellite 21 turbine blades operated at 1500° F. The coating also prevented corrosion of the Refractaloy 26, a corrosion-sensitive nickel-base alloy, and of the Stellite 21, a relatively corrosion-resistant cobalt-base alloy. Although the coating prevented corrosion of both alloys, it had no apparent effect on blade life.

NACA RM E53A19

COMPARISON OF THEORETICALLY AND EXPERIMENTALLY DETERMINED EFFECTS OF OXIDE COATINGS SUPPLIED BY FUEL ADDITIVES ON UNCOOLED TURBINE-BLADE TEMPERATURE DURING TRANSIENT TURBOJET-ENGINE OPERATION. Louis J. Schafer, Jr., Francis S. Stepka and W. Byron Brown. March 1953. 45p. photos., diagrs., tab. (NACA RM E53A19) (Declassified from Confidential, 10/12/54)

An analysis was made to permit the calculation of the effectiveness of oxide coatings in retarding the transient heat flow into turbine blades when the combustion gas temperature of a turbojet engine is suddenly changed. The analysis is checked with experimental data obtained from a turbojet engine whose blades were coated with two different coating materials (silicon dioxide and boric oxide) by adding silicone oil and tributyl borate to the engine fuel. The very thin coatings (approximately 0.001 in.) that formed on the blades produced a negligible effect on the turbine-blade transient temperature response. From the analysis of this report it was possible to predict the turbine rotor-blade temperature response with a maximum error of 40° F.

NACA RM E53E22

BURNING RATES OF SINGLE FUEL DROPS AND THEIR APPLICATION TO TURBOJET COMBUSTION PROCESS. Charles C. Graves. July 1953. 35p. diagrs., photos., tab. (NACA RM E53E22) (Declassified from Confidential, 10/12/54)

Burning rates were determined for single isooctane drops suspended in various quiescent oxygen-nitrogen atmospheres at room temperature and pressure. The burning rates were compared with those predicted by a previously developed theory based on a heat- and mass-transfer mechanism and with values predicted by a modification to this theory. The drop-burning-rate data were applied to equations for a burning fuel spray in order to calculate the predicted change in burning rate of a fuel spray with variation in oxygen concentration. The results so obtained were compared with the change in combustion efficiency of a single turbojet combustor with inlet oxygen concentration, as determined in a previous investigation. The drop burning rates were proportional to drop diameter and increased approximately 34 percent when oxygen concentration of the surrounding oxygen-nitrogen atmosphere was raised from 17.0 to 34.9 percent by volume. The experimentally determined burning rates agreed well with those predicted by the modified heat- and mass-transfer theory. The predicted change in combustion efficiency with inlet oxygen concentration was appreciably smaller than that observed in the combustor tests.

NACA RM L51E24a

BUFFETING-LOAD MEASUREMENTS ON A JET-POWERED BOMBER AIRPLANE WITH REFLEXED FLAPS. John A. See and William S. Aiken, Jr. August 1951. 28p. diagrs., 3 tabs. (NACA RM L51E24a) (Declassified from Confidential, 10/12/54)

Buffet boundaries, buffeting-load increments for the stabilizers and elevators, and buffeting bending-moment increments for the stabilizers and wings as measured in gradual maneuvers for a jet-powered bomber airplane equipped with reflexed flaps and ailerons and tail tip incidence changes are presented and compared with similar results for the original airplane configuration. The Mach numbers of the tests ranged from 0.35 to 0.81 at pressure altitudes close to 30,000 feet. The predominant buffeting frequencies were close to the natural frequencies of the structural components. The magnitudes and trends of buffeting-load coefficients with Mach number for the reflexed-flap configuration were similar to those for the original configuration.

NACA RM L51G13

AN INVESTIGATION OF PROPELLER VIBRATIONS EXCITED BY WING WAKES. W. H. Gray and William Solomon. January 1952. 31p. diagrs., photo., tab. (NACA RM L51G13) (Declassified from Confidential, 10/12/54)

This paper shows the effect of airspeed and wing drag on the magnitude of vibratory stresses experienced by a propeller operating in a wing wake. It establishes the linearity of the relation between the stresses and the velocity at a fixed value of wing drag coefficient and between stress and drag coefficient at a fixed velocity. It also shows that an augmented stress may be experienced by a propeller operating too close behind the wing trailing edge.

NACA RM L51I12

PRESSURE PULSATIONS ON RIGID AIRFOILS AT TRANSONIC SPEEDS. Milton D. Humphreys. December 1951. 21p. diagrs., photos., tab. (NACA RM L51I12) (Declassified from Confidential, 10/12/54)

The effect of changes in Mach number, thickness ratio, and angle of attack on the amplitude of the instantaneous pressure pulsations acting on airfoils ranging in thicknesses from 4 to 12 percent chord has been obtained at transonic speeds, and the corresponding flows past the airfoils were recorded by high-speed schlieren motion pictures. The results indicate that reduction in airfoil thickness was accompanied by marked reductions in the severity of the aerodynamic pressure pulsations which contribute to airplane buffeting.

NACA RM L51J24

THE UNSYMMETRICAL LOAD AND BENDING MOMENT ON THE HORIZONTAL TAIL OF A JET-POWERED BOMBER MEASURED IN SIDESLIPPPING FLIGHT. T. V. Cooney. January 1952. 19p. diagrs., tab. (NACA RM L51J24) (Declassified from Confidential, 10/12/54)

Results are presented of an analysis of unsymmetrical tail-load and bending-moment measurements made during sideslipping flight tests of a jet-powered bomber airplane having a horizontal tail with 12° of geometric dihedral. The unsymmetrical loads and moments due to dihedral and to induction effects from the vertical tail are deduced from the measurements. A comparison of the results with estimates based on available theory was found to be favorable, suggesting that existing methods might be used to modify present arbitrary design requirements relating to unsymmetrical flight conditions.

NACA RM L51K08

LOW-SPEED STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF 60° TRIANGULAR-WING AND MODIFIED 60° TRIANGULAR-WING MODELS HAVING HALF-DELTA AND HALF-DIAMOND TIP CONTROLS. Jacob H. Lichtenstein and Byron M. Jaquet. February 1952. 36p. diagrs., photos., tab. (NACA RM L51K08) (Declassified from Confidential, 10/12/54)

The results are presented of an investigation made in the Langley stability tunnel to determine the low-speed static longitudinal stability and control effectiveness characteristics of a basic and a modified 60° triangular-wing model having 10-percent-wing-area half-delta and half-diamond, and 5-percent-wing-area half-diamond tip controls. Comparisons are made between the half-delta and half-diamond controls and between the basic and modified configurations.

NACA RM L51K19

WIND-TUNNEL INVESTIGATION OF A SHIELDED TOTAL-PRESSURE TUBE AT TRANSONIC SPEEDS. William Gracey, Albin O. Pearson and Walter R. Russell. January 1952. 8p. diagrs. (NACA RM L51K19) (Declassified from Confidential, 10/12/54)

The variation of total-pressure error with angle of attack of a shielded total-pressure tube having a curved venturi entry has been determined through an angle-of-attack range of 0° to 60° at Mach numbers ranging from 0.90 to 1.10. The results showed that the tube measured total pressure correctly (to within 1 percent of the impact pressure) for angles of attack up to about 57° at a Mach number of 0.90 and 56° at a Mach number of 1.10.

NACA RM L51K23

THE INTERFERENCE EFFECTS OF A BODY ON THE SPANWISE LOAD DISTRIBUTIONS OF TWO 45° SWEPTBACK WINGS OF ASPECT RATIO 8 FROM LOW-SPEED TESTS AT A REYNOLDS NUMBER OF 4×10^6. Albert P. Martina. February 1952. 48p. diagrs., photo., 2 tabs. (NACA RM L51K23) (Declassified from Confidential, 10/12/54)

Tests of two wing-body combinations have been conducted in the Langley 19-foot pressure tunnel at a Reynolds number of 4×10^6 and a Mach number of 0.19 to determine the effects of the bodies on the wing span load distributions. The wings had 45° sweepback of the quarter-chord line, aspect ratio 8.02, and taper ratio 0.45. One wing was untwisted and incorporated NACA 63_1A012 airfoil sections in the streamwise direction; the second wing was twisted and cambered. The wings were mounted in mid-high-wing positions on identical bodies of revolution of 10:1 fineness ratio having maximum diameters of 10 percent of the spans. The effects on the incremental loading due to the body resulting from wing incidence, upper-surface wing fences, and flap deflection were also determined for the plane wing. The body effects as calculated by using several existing methods are compared with the experimental results.

NACA RM L51K28

LONGITUDINAL FREQUENCY-RESPONSE CHARACTERISTICS OF THE DOUGLAS D-558-I AIRPLANE AS DETERMINED FROM EXPERIMENTAL TRANSIENT-RESPONSE HISTORIES TO A MACH NUMBER OF 0.90. Ellwyn E. Angle and Euclid C. Holleman. February 1952. 28p. diagrs., tab. (NACA RM L51K28) (Declassified from Confidential, 10/12/54)

Transient responses from elevator pulses of the Douglas D-558-I research airplane are analyzed by the Fourier transform to give the longitudinal frequency response of the airplane to a Mach number of 0.90 of altitudes between 30,000 and 37,000 feet.

NACA RM L51K28a

FLUTTER INVESTIGATION OF TWO THIN, LOW-ASPECT-RATIO, SWEPT, SOLID, METAL WINGS IN THE TRANSONIC RANGE BY USE OF A FREE-FALLING BODY. W. T. Lauten, Jr. and Maurice A. Sylvester. February 1952. 12p. diagrs., photo., 2 tabs. (NACA RM L51K28a) (Declassified from Confidential, 10/12/54)

Two thin, interceptor-type (low-aspect ratio), 45° sweptback, untapered wings of solid metal construction have been tested for flutter up to a Mach number of 1.23 by the free-falling-body technique. No flutter was obtained. Flutter calculations yielded results which showed that two-dimensional compressible flow theory is not adequate for predicting flutter for this type of low-aspect-ratio wing in the transonic speed range.

NACA RM L51L04

WIND-TUNNEL INVESTIGATION AT HIGH AND LOW SUBSONIC MACH NUMBERS OF A THIN SWEPTBACK WING HAVING AN AIRFOIL SECTION DESIGNED FOR HIGH MAXIMUM LIFT. Stanley F. Racisz and Nicholas J. Paradiso. February 1952. 46p. diagrs., photo., tab. (NACA RM L51L04) (Declassified from Confidential, 10/12/54)

An investigation has been made of a semispan wing with 45° sweepback, aspect ratio 4, and taper ratio 0.6, equipped with an airfoil section designed to have high maximum lift at low Mach numbers. The lift, drag, and pitching-moment characteristics were determined at Reynolds numbers ranging from 2×10^6 to 9×10^6 for Mach numbers below 0.2 for the wing with and without a split flap. The characteristics of the plain wing were also determined for several values of the Reynolds number at Mach numbers up to about 0.95. The results are compared with results obtained from tests of a wing with the same plan form but with the NACA 65A006 airfoil section.

NACA RM L51L11

AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A TAPERED 45° SWEPTBACK WING OF ASPECT RATIO 3 HAVING A FULL-SPAN FLAP TYPE OF CONTROL WITH OVERHANG BALANCE. TRANSONIC-BUMP METHOD. Vernard E. Lockwood and John R. Hagerman. January 1952. 24p. diagrs. (NACA RM L51L11) (Declassified from Confidential, 10/12/54)

Lift, pitching-moment, rolling-moment, and flap hinge-moment coefficients were obtained by the transonic bump method on a 45° sweptback wing of aspect ratio 3, and taper ratio of 0.5, and an NACA 64A010 section, employing a 0.254-chord full-span flap. The flap had a 50-percent flap-chord elliptical-nose overhang. The investigation was made at angles of attack of -4°, 0°, 4°, and 8°, flap deflections from -28° to 6°, and Mach numbers from 0.6 to 1.15. The results are compared with the same flap without overhang.

NACA RM L51L14

LOW-SPEED TESTS OF A FREE-TO-YAW MODEL IN TWO WIND TUNNELS OF DIFFERENT TURBULENCE. Jones F. Cahill and John D. Bird. February 1952. 12p. diagrs., photos. (NACA RM L51L14) (Declassified from Confidential, 10/12/54)

Tests have been made at low speeds in the Langley low-turbulence pressure tunnel which has a very low turbulence level and the Langley stability tunnel which has a turbulence level approximately ten times as great in order to determine the extent of any resulting oscillations of a model mounted with freedom in yaw and in order to demonstrate the extent to which directional fluctuations in an air stream can be responsible for such oscillations. Tests covered a range of dynamic pressures from 4 to 175 pounds per square foot with associated ranges of Reynolds numbers and Mach numbers from 1.5×10^6 to 4.6×10^6 and 0.05 to 0.34, respectively.

NACA RM L51L19

PRELIMINARY INVESTIGATION OF THE EFFECTS OF A PADDLE BALANCE ON THE CONTROL CHARACTERISTICS AT TRANSONIC SPEEDS OF A TAPERED 45.58° SWEPTBACK WING OF ASPECT RATIO 3 HAVING A FULL-SPAN FLAP-TYPE CONTROL. William C. Moseley, Jr. February 1952. 24p. diagrs., photo. (NACA RM L51L19) (Declassified from Confidential, 10/12/54)

A preliminary investigation at transonic speeds was made on a wing having a quarter-chord line swept back 45.58°, an aspect ratio of 3, a taper ratio of 0.5, and an NACA 64A010 airfoil section. The Reynolds number of the tests was approximately 1,000,000. The wing had a full-span flap tested with and without a paddle balance. The paddle balance was capable of balancing excessive control hinge moments with only slight effects on the lift and rolling-moment characteristics.

CURRENT NACA REPORTS

NACA Rept. 1133

MECHANISM OF START AND DEVELOPMENT OF AIRCRAFT CRASH FIRES. I. Irving Pinkel, G. Merritt Preston and Gerald J. Pesman. 1953. iii, 52p. diagrs., photos., 2 tabs. (NACA Rept. 1133. Formerly RM E52F06)

Full-scale aircraft crashes were made to investigate the mechanism of the start and development of aircraft crash fires. The results are discussed herein. This investigation revealed the characteristics of the ignition sources, the manner in which the combustibles spread, the mechanism of the union of the combustibles and ignition sources, and the pertinent factors governing the development of a crash fire as observed in this program.

NACA Rept. 1134

PHOTOGRAPHIC INVESTIGATION OF COMBUSTION IN A TWO-DIMENSIONAL TRANSPARENT ROCKET ENGINE. Donald R. Bellman, Jack C. Humphrey and Theodore Male. 1953. ii, 12p. diagrs., photos., tab. (NACA Rept. 1134. Formerly RM E8F01)

Motion pictures at camera speeds up to 3000 frames per second were taken of the combustion of liquid oxygen and gasoline in a 100-pound thrust rocket engine. The effect of seven methods of propellant injection on the uniformity of combustion was investigated. The flame front was generally found to extend to the injector faces and all the injection systems showed considerable nonuniformity of combustion. Pressure vibration records indicated combustion vibrations that corresponded to resonant-chamber frequencies.

NACA Rept. 1151

THE EFFECTS ON DYNAMIC LATERAL STABILITY AND CONTROL OF LARGE ARTIFICIAL VARIATIONS IN THE ROTARY STABILITY DERIVATIVES. Robert O. Schade and James L. Hassell, Jr. 1953. ii, 24p. diagrs., photo., 2 tabs. (NACA Rept. 1151. Formerly TN 2781)

The results of an experimental and theoretical investigation of the effects of large artificial variations of four rotary stability derivatives on the dynamic lateral stability and control of a 45° sweptback-wing airplane model are presented. The experimental results are presented mainly in the form of flight ratings for stability, control, and general flight behavior. Calculations of period and damping and of the response to rolling and yawing disturbances are also presented.

NACA Rept. 1163

A VISUALIZATION STUDY OF SECONDARY FLOWS IN CASCADES. Howard Z. Herzig, Arthur G. Hansen and George R. Costello. 1954. ii, 51p. diagrs., photos. (NACA Rept. 1163. Formerly TN 2947; RM E52F19)

Flow-visualization techniques are employed to ascertain the streamline patterns of the nonpotential, secondary flows in the boundary layers of cascades, thereby providing a basis for more extended analyses in turbomachines. The three-dimensional deflection of the end-wall boundary layer results in the formation of a vortex well up in each cascade passage. The size and tightness of the vortex generated depend upon the main flow turning in the cascade passage. Once formed, a vortex resists turning in subsequent blade rows. This results in unfavorable angles of attack and possible flow disturbances on the pressure surfaces of subsequent blade rows when the vortices impinge on these surfaces. Two major tip-clearance effects are observed: the formation of a tip-clearance vortex, and the scraping effect of a blade with relative motion past the wall boundary layer. The flow patterns indicate methods for improving the blade-tip loading characteristics of compressors and of low- and high-speed turbines.

NACA Rept. 1164

CONVECTION OF A PATTERN OF VORTICITY THROUGH A SHOCK WAVE. H. S. Ribner. 1954. ii, 17p. diagrs. (NACA Rept. 1164. Formerly TN 2864)

An arbitrary weak spatial distribution of vorticity can be represented in terms of plane sinusoidal shear waves of all orientations and wave lengths (Fourier integral). The analysis treats the passage of a single representative weak shear wave through a plane shock and shows refraction and modification of the shear wave with simultaneous generation of an acoustically intense sound wave. Applications to turbulence and to noise in supersonic wind tunnels are indicated.

NACA Rept. 1171

EFFECT OF HORIZONTAL-TAIL SPAN AND VERTICAL LOCATION ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT TAIL ASSEMBLY IN SIDESLIP. Donald R. Riley. 1954. ii, 20p. diagrs., photos., tab. (NACA Rept. 1171. Formerly TN 2907)

Wind-tunnel results on the effect of hoirzontal-tail span and vertical location of the horizontal tail relative to the vertical tail on the aerodynamic

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

characteristics of an unswept vertical-tail assembly in sideslip are presented. By applying the well-known discrete-horseshoe-vortex method used for wings to the problem of intersecting surfaces, theoretical span loadings were obtained for each of the configurations tested. Calculated values obtained from the span loadings are compared with experimental results.

NACA Rept. 1172

A STUDY OF THE APPLICATION OF POWER-SPECTRAL METHODS OF GENERALIZED HARMONIC ANALYSIS TO GUST LOADS ON AIRPLANES. Harry Press and Bernard Mazelsky. 1954. ii, 17p. diagrs., 2 tabs. (NACA Rept. 1172. Formerly TN 2853)

The applicability of some results from the theory of generalized harmonic analysis to the analysis of gust loads on airplanes in continuous rough air is examined. The input and output relations in terms of power spectrums are used to relate the standard deviation (root mean square) of loads in continuous rough air to the gust response characteristics of the airplane and the spectral characteristics of atmospheric turbulence. For the case of a normally distributed output, which appears from experimental evidence to apply to a homogeneous turbulence condition, the probability distribution of loads is shown to be a simple function of the output power spectrum. In order to illustrate the application of power-spectral analysis to gust loads and to obtain an insight into the relation between loads in continuous rough air and the gust response characteristics of the airplane, two selected series of calculations are presented. The results of these applications are compared with those obtained from calculations for single gusts and their implications are discussed.

NACA TM 1366

HEAT TRANSFER BY FREE CONVECTION FROM HORIZONTAL CYLINDERS IN DIATOMIC GASES. (Wärmeübergang bei breier Strömung am wagrechten Zylinder in zweiatomigen Gasen). R. Hermann. November 1954. 73p. diagrs., photos., 6 tabs. (NACA TM 1366. Trans. from VDI Forschungsheft, No. 379, 1936)

Heat transfer by free convection from horizontal cylinders in diatomic gases is investigated theoretically and experimentally. The heat transfer is given by the theoretical equation $Nu = 0.37(Gr)^{1/4}$ for $10^4 < Gr < 3 \times 10^8$. Experimental determinations of velocity, temperature, and heat transfer are in good agreement with the theory. It is found that the total heat transfer and the boundary-layer development at the upper stagnation point and at the upper edge, respectively, of a horizontal cylinder are equivalent to the respective quantities for a vertical plate which transfers heat on both sides and is 1.31 times the cylinder diameter. A review and discussion of previous investigations of free-convection heat transfer from horizontal cylinders is included.

NACA TM 1373

ON FORCE-DEFLECTION DIAGRAMS OF AIRPLANE SHOCK ABSORBER STRUTS. FIRST, SECOND, AND THIRD PARTIAL REPORTS. (Zur Kenntnis der Kraftwegdiagramme von Flugzeugfederbeinen). K. Schlaefke. November 1954. 48p. diagrs., 4 tabs. (NACA TM 1373. Trans. from Technische Berichte, v. 11, nos. 2, 4, & 5, 1944)

This paper, which is presented in three parts, is an analytical study of the behavior of landing-gear shock struts, with various types of assumptions for the shock-strut characteristics. The effects of tire springing are neglected. The first part compares the behavior of struts with linear and quadratic damping. The second part considers struts with nonlinear spring characteristics and linear or quadratic damping. The third part treats the oleo-pneumatic strut with air-compression springing without damping and with damping proportional to velocity. It is indicated how the damping factor can be determined by experiment.

NACA TM 1378

DETERMINATION OF THE ELASTIC CONSTANTS OF AIRPLANE TIRES. (Ermittlung der elastischen Konstanten von Flugzeugreifen). Boeckh. November 1954. 39p. diagrs. (NACA TM 1378. Trans. from Focke-Wulf Flugzeugbau G.m.b.H, Bremen, V.13.3703)

Measurements were made of the distortion of four German aircraft tires, from about 22 to 28 inches in diameter, at several vertical loadings. For each vertical loading measurements were made of the tire distortion under several lateral, tangential and torsional loadings.

NACA TM 1381

ON THE DETERMINATION OF CERTAIN BASIC TYPES OF SUPERSONIC FLOW FIELDS. (Sulla determinazione di alcuni tipi di campi di corrente ipersonora). Carlo Ferrari. November 1954. 17p. diagrs. (NACA TM 1381. Trans. from Rendiconti della R. Accademie Nazionale dei Lincei, Series 8, v. 7, no. 6, Dec. 1949)

A discussion is given of the application of Fourier series techniques to the problems of linearized supersonic flow. The formulation presented is an extension of the doublet type of "fundamental solution" to higher order types of singularity. The equations developed have application to wing theory but are primarily of importance in wing-body interaction problems. A specific example of a wing-body interference problem is discussed in light of the presented methods.

NACA TN 3217

THE INFLUENCE OF WHEEL SPIN-UP ON LANDING-GEAR IMPACT. W. Flügge and C. W. Coale, Stanford University. October 1954. ii, 107p. diagrs., 8 tabs. (NACA TN 3217. Continuation of TN 2743)

This report deals with the influence of wheel drag on landing-gear performance. The differential equations are developed and solved by numerical integration and by an analytical method. Emphasis is placed on dropping influences of minor importance to simplify the computations. Consideration is also given to the influence of offset wheels, inclined shock struts, and friction due to ovalization of the shock-strut cylinder under bending loads.

NACA TN 3219

VISCOSITY CORRECTIONS TO CONE PROBES IN RAREFIED SUPERSONIC FLOW AT A NOMINAL MACH NUMBER OF 4. L. Talbot, University of California. November 1954. 39p. diagrs., photo., 4 tabs. (NACA TN 3219)

Viscosity correction data were obtained for a set of geometrically similar cone probes in supersonic rarefied air flow at a nominal Mach number of 4. Additional experiments were made to determine cone surface pressure distributions and the effects of variable orifice size on the measurement of cone surface pressure. Pressure distributions near the vertex were compared with the tangent-cone and linearized theories.

NACA TN 3242

PRELIMINARY RESULTS FROM FLOW-FIELD MEASUREMENTS AROUND SINGLE AND TANDEM ROTORS IN THE LANGLEY FULL-SCALE TUNNEL. Harry H. Heyson. November 1954. 19p. diagrs., photos. (NACA TN 3242)

Measurements of the flow angles and velocities near lifting helicopter rotors, both single and tandem, at a tip-speed ratio of 0.15 are presented and compared with those of theory. The comparison indicates that the theory is sufficiently accurate for use in preliminary design calculations. The flow behind a rotor is shown to be very much like the flow behind a wing.

NACA TN 3252

DESCRIPTION AND PRELIMINARY FLIGHT INVESTIGATION OF AN INSTRUMENT FOR DETECTING SUBNORMAL ACCELERATION DURING TAKE-OFF. Garland J. Morris and Lindsay J. Lina. November 1954. 19p. diagrs., photos. (NACA TN 3252)

An instrument actuated by longitudinal acceleration and impact pressure has been proposed which would give a quick and easily recognizable quantitative indication of loss in airplane acceleration during take-off. A preliminary evaluation from flight tests of a simplified prototype instrument mounted in a jet trainer has been made. The instrument was found to be satisfactory and the response of the indicator to simulated partial power loss was rapid.

NACA TN 3260

SMOKE STUDY OF NOZZLE SECONDARY FLOWS IN A LOW-SPEED TURBINE. Milton G. Kofskey and Hubert W. Allen. November 1954. 24p. diagrs., photos. (NACA TN 3260)

Still and motion pictures were made of boundary-layer and wake secondary-flow phenomena visualized by smoke. Two annular cascades of turbine nozzles were used, both designed for constant discharge angle but differing in blade shape and suction-surface velocity distribution. Flows were similar to those obtained with pressure and angle measurements at near-sonic airspeeds. Boundary-layer cross-channel and trailing-edge radial flows caused vortices and an accumulation of low-momentum air at the hub, which may affect flow in following blade rows. Motion of a downstream rotor blade row produced pulsations in trailing-edge radial flow. The motion-picture supplement may be obtained on loan from NACA Headquarters, Washington, D. C.

NACA TN 3268

SHEARING-STRESS MEASUREMENTS BY USE OF A HEATED ELEMENT. H. W. Liepmann and G. T. Skinner, California Institute of Technology. November 1954. 27p. diagrs. (NACA TN 3268)

The present report discusses the use of an instrument to determine the local skin-friction coefficient by measurement of heat transfer from small elements embedded in the surface. The range of application of such instruments is discussed and experimental data are presented to show that a simple instrument consisting of an ordinary hot-wire cemented into a groove in the surface can be used to obtain laminar and turbulent skin-friction coefficients with a single calibration.

NACA TN 3283

AERODYNAMIC FORCES, MOMENTS, AND STABILITY DERIVATIVES FOR SLENDER BODIES OF GENERAL CROSS SECTION. Alvin H. Sacks. November 1954. (i), 74p. diagrs., 2 tabs. (NACA TN 3283)

Formulas are developed for forces and moments in terms of the body shape and motions, and for stability derivatives in terms of the mapping functions of the cross sections. Relationships are found among the various derivatives, and calculations are made for several configurations. The influence of the squared terms in the pressure relation is demonstrated, and the use of the apparent mass concept is discussed in detail.

NACA TN 3286

GENERALIZED INDICIAL FORCES ON DEFORMING RECTANGULAR WINGS IN SUPERSONIC FLIGHT. Harvard Lomax, Franklyn B. Fuller and Loma Sluder. November 1954. 74p. diagrs., tab. (NACA TN 3286)

A method is presented for determining the time-dependent flow over a rectangular wing moving with a supersonic forward speed and undergoing small vertical distortions expressible as polynomials involving spanwise and chordwise distances. Results are expressed in terms of generalized indicial forces. Numerical results for Mach numbers of 1.1 and 1.2 are given for polynomials of the first and fifth degree in the chordwise and spanwise directions, respectively, on a wing of aspect ratio 4.

NACA TN 3291

EXPERIMENTAL INVESTIGATION OF NOTCH-SIZE EFFECTS ON ROTATING-BEAM FATIGUE BEHAVIOR OF 75S-T6 ALUMINUM ALLOY. W. S. Hyler, R. A. Lewis and H. J. Grover, Battelle Memorial Institute. November 1954. 47p. diagrs., photos., 12 tabs. (NACA TN 3291)

This investigation was initiated to study the influence of size, particularly the notch size, on extruded 75S-T6 aluminum-alloy test specimens. Unnotched and notched specimens with five different minimum-section diameters were tested. For each size a semicircular groove was tested and for the largest diameter specimen a V-notch was also tested. A method of surface preparation was selected that would produce comparable surface finishes in different-sized notched and unnotched specimens.

NACA TN 3292

INFLUENCE OF EXPOSED AREA ON STRESS-CORROSION CRACKING OF 24S ALUMINUM ALLOY. William H. Colner and Howard T. Francis, Armour Research Foundation. November 1954. 22p. diagrs., photos., tab. (NACA TN 3292)

Results are presented of a study of the "area effect" in 24S aluminum alloy. This effect is the phenomenon whereby small exposed areas show long times to stress-corrosion failure, whereas large areas show short times. The effects of stress level, degree of sensitivity of the alloy, and hydrogen peroxide concentration in the corrosion medium were studied. Hydrogen peroxide decomposition and the substitution of oxygen for peroxide were also investigated.

NACA TN 3305

SOME MEASUREMENTS AND POWER SPECTRA OF RUNWAY ROUGHNESS. James H. Walls, John C. Houbolt and Harry Press. November 1954. 27p. diagrs., tab. (NACA TN 3305)

Measurements of actual runway roughness obtained by a profile-survey method (engineer's level) are presented. Data were obtained from a survey of a relatively rough runway and a smooth runway. The results of this study are presented as roughness profiles of the runways surveyed and in the form of power spectra.

NACA TN 3308

AN EXPLORATORY INVESTIGATION OF SOME TYPES OF AEROELASTIC INSTABILITY OF OPEN AND CLOSED BODIES OF REVOLUTION MOUNTED ON SLENDER STRUTS. S. A. Clevenson, E. Widmayer, Jr. and Franklin W. Diederich. November 1954. 44p. diagrs., photos., 3 tabs. (NACA TN 3308. Formerly RM L53E07)

The aeroelastic instability of rigid open and closed bodies of revolution mounted on thin, flexible struts has been investigated experimentally at low speeds. Three types of instability were observed - coupled flutter, divergence, and an uncoupled oscillatory instability which consists in continuous or intermittent small-amplitude yawing oscillations. An attempt has been made to calculate the airspeeds and, in the case of the oscillatory phenomena, the frequencies at which these types of instability occur by using slender-body theory for the aerodynamic forces on the bodies.

NACA TN 3310

INVESTIGATION OF STATIC STRENGTH AND CREEP BEHAVIOR OF AN ALUMINUM-ALLOY MULTIWEB BOX BEAM AT ELEVATED TEMPERATURES. Eldon E. Mathauser. November 1954. 21p. diagrs., photos., 4 tabs. (NACA TN 3310)

Results of an investigation to determine static strength and creep behavior at elevated temperatures of 24S-T3 aluminum-alloy multiweb box beams are presented. Methods that were used to predict failure stresses in the static-strength tests were in good agreement with the experimental results. Creep deflections and creep lifetimes are presented for beams subjected to constant load and various heating conditions. Lifetime is satisfactorily predicted from material stress-rupture data when tensile failure occurs at both constant and varying temperatures.

NACA TN 3313

SOME MEASUREMENTS OF ATMOSPHERIC TURBULENCE OBTAINED FROM FLOW-DIRECTION VANES MOUNTED ON AN AIRPLANE. Robert G. Chilton. November 1954. 22p. diagrs., photo., tab. (NACA TN 3313)

The power spectrum of high-frequency turbulence in the atmosphere was calculated from measurements made in flight. The spectrum was found to display an inverse variation with the square of frequency. This variation is in agreement with the high-frequency asymptote of the spectrum form commonly associated with isotropic turbulence. Flow-direction vanes were used to measure vertical and horizontal components of gust velocity relative to the airplane and normal to the flight direction. The power spectral densities of the two components were, for practical purposes, equal.

NACA TN 3315

TENSILE AND COMPRESSIVE STRESS-STRAIN PROPERTIES OF SOME HIGH-STRENGTH SHEET ALLOYS AT ELEVATED TEMPERATURES. Philip J. Hughes, John E. Inge and Stanley B. Prosser. November 1954. 32p. diagrs., photos., 6 tabs. (NACA TN 3315)

Results of tensile and compressive stress-strain tests at temperatures up to 1,200° F are presented for SAE 4340, Hy-Tuf, Stainless W, and Inconel X sheet materials which had ultimate tensile strengths at room temperature in the 170 to 220 ksi range. Representative tensile and compressive stress-strain curves are given for each material at the test temperatures. Secant and tangent moduli, obtained from the compressive data, are included.

NACA TN 3343

SUBSONIC EDGES IN THIN-WING AND SLENDER-BODY THEORY. Milton D. Van Dyke. November 1954. 26p. diagrs. (NACA TN 3343)

A simple technique is presented for correcting the singularities predicted by thin-wing and slender-body theory at subsonic edges. Thus, Lighthill's rule for speeds on round-nosed airfoils in incompressible flow is extended to higher approximations, compressible flow, three-dimensional wings, sharp edges, and slender bodies of revolution.

NACA TN 3345

ARRANGEMENT OF FUSIFORM BODIES TO REDUCE THE WAVE DRAG AT SUPERSONIC SPEEDS. Morris D. Friedman and Doris Cohen. November 1954 23p. diagrs. (NACA TN 3345. Formerly RM A51I20)

Using linearized slender-body theory and reverse-flow theorems, the wave drag of a system of fusiform bodies at zero angle of attack and supersonic speeds is studied to determine the effect of varying the relative location of the component parts. It is found that in certain arrangements the interference effects are beneficial, and may even result in a two- or three-body system having no more wave drag than the principal body alone. The most favorable location appears to be one in which the maximum cross section of the auxiliary body is slightly forward of the Mach cone from the tail of the main body.

TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. SEPETIR - PSEUDOSINDORA PALUSTRIS - SARAWAK. (POUNDS PER CUBIC FOOT AT 15 PER CENT MOISTURE CONTENT) PROGRESS REPORT TWENTY-FOUR. August 1954. 17p. (Forest Products Research Lab.)

Thirteen 5-ft 3-in. billets were used for obtaining yield data and two were used for processing trials. Good green veneer was smooth and free from defects except end splits, which were rather numerous and hindered spooling. The extreme straightness of the grain resulted in easy breakage and made high-speed power spooling impossible. Generally the veneer was similar in texture to afara. The heartwood and sapwood had similar drying properties but the sapwood is a greenish color very distinct from the pinkish heartwood. It is classified as being unsuited to British mills but is technically sound for plywood making and might be of value for this purpose in the country of origin.

THE EFFECT OF SURFACE FINISH ON THE FATIGUE RESISTANCE OF TWO ALUMINIUM ALLOYS. N. J. F. Gunn. March 1954. 19p. diagrs., 13 tabs. (RAE Tech. Note Met. 196)

Tests have been made on two aluminum alloys D.T.D. 683 and B.S.S. 6L1 to ascertain the effect of four finishes on their fatigue strength. The finishes were: rough machined, fine machined, circumferentially polished, and longitudinally polished. The fatigue:ultimate ratios for both materials were found to be approximately: rough machined - 0.30; fine machined - 0.30; circumferentially polished - 0.32; longitudinally polished - 0.34.

A GENERALISATION OF THE NYQUIST STABILITY CRITERION WITH PARTICULAR REFERENCE TO PHASING ERROR. R. H. Merson. May 1954. 9p. diagr. (RAE Tech. Note GW 316)

The effect of phasing error on the stability of a two-dimensional linear servomechanism is considered and it is shown that the system will be stable if the phase margin at the cut-off frequency exceeds the phasing error. The more general case of a number of identical servos with cross coupling is investigated and a generlization of the Nyquist criterion for stability is formulated.

DIELECTRIC MEASUREMENTS ON SOME LAMINATING RESINS AND THE EFFECT OF MOISTURE ABSORPTION AND TEMPERATURE. A. A. Fyall and J. H. Sewell. June 1954. 29p. diagrs., 16 tabs. (RAE Tech. Note Chem. 1233)

Values are given for the dielectric constant and loss tangent of several resins having potential application in the fabrication of glass-fiber reinforced radomes. Dielectric properties were measured on dry materials and also on materials subjected, for varying periods of time, to tropical conditioning in a humidity chamber. When the resin composition could be varied, that giving the optimum dielectric performance was ascertained. Where possible, measured values were compared with those obtained theoretically. The merits of the resins are compared and their best values summarized.

THE ESTIMATION OF SIZE ON GLASS FABRICS: TWO NEW METHODS. E. Haythornthwaite and R. B. King. June 1954. 15p. diagrs., photo., 3 tabs. (RAE Tech. Note Chem. 1231)

Two new methods for the estimation of the size content of glass fabrics have been examined. One method depends on the gasometric estimation of carbon dioxide formed from the carbon present on a fabric sample. The other is a modified volatile loss method suitable for control purposes and designed to minimize the errors inherent in previous methods. Excellent correlation between the results from the two methods was obtained.

CALIBRATION AND DESCRIPTION OF THE EXHAUSTER SECTION OF THE HIGH ALTITUDE TEST PLANT. E. Simpson and F. S. Margrie. May 1954. 47p. diagrs., photos. (RAE Tech. Note Aero 2303. Formerly RAE Tech. Memo. Aero 329)

This note gives a brief description of the Ex L. F. A. Exhauster Plant now installed at R. A. E. as a unit of the High Altitude Test Plant. The means used to calibrate the plant are described. Results of calibrations indicate that with different combinations of units, at mass flows varying from 1.5 to 4.5 lb/sec pressures of 0.75 inch Hg to 2 inches Hg absolute could be obtained, and at mass flows varying from 3 lb/sec to 8.5 lb/sec pressures of 1.35 inches Hg to 3.3 inches Hg were obtainable. Approximate relative efficiencies are given and lines of possible improvement indicated. A detailed description of the plant and the modifications introduced as a result of operational experience is given. This note is the first of a series describing and giving calibrations of various sections of the High Altitude Plant.

A SIMPLE APPROACH TO THE THEORY OF SECONDARY FLOWS. J. H. Preston. December 10, 1953. 19p. diagrs. (ARC 16,394; FM 1996; EA 320)

A simple method is developed for computing the secondary trailing vorticity which arises when a nonuniform stream is turned. The essential results derived by Squire and Winter and by Hawthorne are obtained with a minimum of analysis and the reason for the secondary trailing vorticity is physically evident. It is shown that for a sudden deflection of a nonuniform stream, no trailing vorticity is set up in the exit flow and hence there is no secondary motion. It is also shown that for small angles of deflection there is no net circulation downstream of a cascade of finite dimensions and it is inferred that this should be true also for large deflections.

Royal Aircraft Establishment (Gt. Brit.)
A CROSSED-FIELDS MULTIPLIER. J. A. Roberts and D. C. Pressey. April 1954. 88p. diagrs., photos., tab. (RAE Tech. Note Arm. 516)

Fed-back d-c amplifiers controlling crossed electric and magnetic fields in a simple bucket cathode-ray tube, VCRX. 340, enable a natural product law to be used in this high-speed, four-quadrant multiplier for analogue computers. The development, design, and theoretical and measured performance are described. Direct measurement shows the static errors to be less than 1 percent of full output, while the change of scale-factor with frequency does not reach 1 percent until 10 kc/s. The power consumption is only 50 w total. The zero drift is small and the long-term stability excellent.

ON THE TURBULENT BOUNDARY LAYER ON A FLAT PLATE OF FINITE WIDTH. A. A. Townsend. March 3, 1954. 10p. diagrs. (ARC 16,618; FM 2042)

A theory is developed for edge effect on the turbulent boundary layer on a flat plate of finite width by considering the equations of motion for the flow.

N-34113*

Aeronautical Research Council (Gt. Brit.)
AN EXPERIMENTAL INVESTIGATION OF THE INTERACTION OF A SHOCK WAVE WITH A SUBSONIC STREAM BOUNDED BY A WALL. D. W. Holder, A. Chinneck and G. E. Gadd. February 11, 1954. 17p. diagrs., photos., tab. (ARC 16,559; FM 2025)

A study has been made of a model of a boundary layer consisting of a subsonic stream bounded on one side by a wall and on the other by a supersonic main stream. The subsonic stream was approximately uniform at the point where it first met the main stream, but it became progressively less uniform downstream of this point because of mixing with the main stream and the growth of the boundary layer at the wall. Particular attention is given to the pressure rise which takes place at the wall when a wedge is attached to it. The pressure begins to rise ahead of the apex of the wedge, this upstream effect increases as the Mach number of the secondary stream is reduced.

Advisory Group for Aeronautical Research and Development. SOME ASPECTS OF COMBUSTION OF LIQUID FUEL. Charles C. Graves and Melvin Gerstein. (Scheveningen Netherlands Conference, May 3-7, 1954) 26p. diagrs., photo. (AGARD AG16/M10)

In this paper the combustion of liquid sprays is considered in terms of such individual processes as fuel spray spreading and evaporation. In addition, the efficiency of combustion of liquid fuels in turbojet combustors as affected by fuel volatility, spray characteristics, and the burning rate of single drops is treated. The scope of this paper is limited to a discussion of these factors normally associated with diffusion flames.

Advisory Group for Aeronautical Research and Development. A SCHEME OF AUTOMATIC DATA REDUCTION FOR WIND TUNNELS. K. V. Diprose. (London AGARD Conference, September 3-11, 1953) 17p. diagrs., photos. (AGARD AG9/M5)

The need for automatic devices to speedup reduction of data obtained from wind tunnels in the RAE first became urgent during the war. Up to the present little of the analogue computing equipment suggested in the original plan has been constructed. One computer giving tunnel Mach number was constructed in 1948 and has been in operation ever since in the 10- by 7-foot high-speed tunnel. A "breadboard" model of a computer to calculate uncorrected force coefficients has been made. The design of plotting tables as an alternative form of output is well advanced. Their principal use will be in intermittent wind tunnels where time available for a complete run does not permit printing typed answers.

N-30835A*

Advisory Group for Aeronautical Research and Development. A NOTE ON THE USE OF STRAIN GAUGES IN WIND TUNNEL BALANCES. J. R. Anderson. (London AGARD Conference, September 3-11, 1953) 20p. diagrs., photo. (AGARD AG10/M6)

This paper records some of the experience obtained in the use of strain gage balances in the smaller high-speed wind tunnels of Aerodynamics Department, R.A.E. The discussion is therefore a little restricted in scope, being for the most part limited to the use of bonded, resistance type electrical strain gages in force and moment balances intended for use with models ranging from about 0.4 in. to 1.5 in. in diameter. Much of the discussion should prove of interest in the design of larger installations: for example, the comments which are made on the effects of temperature on the strain gages.

Advisory Group for Aeronautical Research and Development. FORMATION ET DEPOT DE CARBONE DANS LES FOYERS DE TURBOMACHINES D'AVIATION. C. Fouré. (Scheveningen Netherlands Conference, May 3-7, 1954) 21p. diagrs., photos. (AGARD AG12/M8)

Operating with accepted fuels, modern reactionary turbines are not seriously troubled by the formation of carbon deposits. The change towards high compression and towards the use of less powerful fuels alter this situation. The role of certain characteristics of fuels have been clarified. A great deal is yet to be learned about additives to reduce deposits, but modifications can be imagined which may reduce the formation of carbon during combustion in order to prevent eventual deposits on the walls.

DESIGN AND OPERATING TECHNIQUES OF VERTICAL SPIN TUNNELS. A. I. Neihouse. (Presented to Wind Tunnel and Model Testing Panel of Advisory Group for Aeronautical Research and Development, Paris, France, November 2-6, 1954) 16p. diagrs., photos., 2 tabs.

Dynamic tests in a spin tunnel, aided by auxiliary tools and techniques including analytical methods, offers a practical method for a better understanding

of the spinning motion and the recovery therefrom. Just how the moments and forces affect the picture, and just what part the stability characteristics of the airplane at large attitude angles play can be determined by proper research effort. That such effort is necessary has been demonstrated in the past and by experiences with current airplanes; that the problem of spin recovery may become more critical is likely. Adequate facilities to do spin research, however, should lead to eventual solution of the existing problem.

TRANSONIC WIND TUNNEL DEVELOPMENT OF THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS. H. Julian Allen. (Presented to Wind Tunnel and Model Testing Panel of Advisory Group for Aeronautical Research and Development, Paris, France, November 2-6, 1954) 22p. diagrs., photo.

The development of transonic wind tunnels at the Langley and Ames Aeronautical Laboratories of the NACA is discussed. Two types of wind tunnels suitable for transonic wind tunnel operation are described: the fixed geometry slotted-wall type and the variable-geometry ventilated wall (slotted or porous) type.

N-33610*

DEVELOPMENT OF TWO HYPERSONIC TEST FACILITIES AT THE NATIONAL ADVISORY COMMITTEE FOR AERONAUTICS, AMES AERONAUTICAL LABORATORY. H. Julian Allen. (Presented to Wind Tunnel and Model Testing Panel of Advisory Group for Aeronautical Research and Development, Paris, France, November 2-6, 1954) 41p. diagrs., photos., tab.

Two facilities for hypersonic research which have been developed at the Ames Aeronautical Laboratory are discussed. The first facility is a wind tunnel which is of interest because of its ability to operate continuously over a wide range of speeds with a not-too-complex drive system; while the second is a combination wind tunnel and ballistics range which allows operation over an even wider range of speeds up to speeds which are very difficult to attain in a wind tunnel of the more conventional type.

UNPUBLISHED PAPERS

N-25802*

THE ROTATING WING AS A RADIATION PROBLEM. (Der rotierende Tragflügel als Strahlungsproblem). Wilhelm Ernsthausen. September 1954. 40p. diagrs., photos. (Trans. from Zeitschrift für angewandte Mathematik und Mechanik, v. 31, no. 1/2, Jan./Feb., 1951, p. 20-35)

The forces exerted upon a wing rotating in a compressible gas correspond to the reaction of its field of sound. Therefore, they may be determined from the energy capacity of this field. The investigation is based on the idea of starting with the field of sound and penetrating into the connections between flow and wave concepts. It deals with the determination of the flow forces stemming from the energy of the sound field which acts on the wing, with the mass motion describing the lift finding its expression in the field in the immediate neighborhood, and the radiation losses responsible for the drag finding theirs in the field in the distance.

N-33628*

APPLICABILITY OF THE LAW OF SIMILITUDE TO CAVITATION. (Zum Ähnlichkeitsgesetz für Hohlraumbildungen). A. Reinhardt. April 1954. 34p. diagrs., photo. (Trans. from Forschung auf dem Gebiete des Ingenieurwesens, Ed. B, v. 6, p. 1-12, Jan.-Feb., 1935, Forschungsheft 370)

Conclusions, derived from the theory of similitude, regarding caviation in flow engines were compiled, supplemented, and investigated as to their practical applicability. Two deviations from Newton's similitude of flow were recognizable in the test results. A number of tests were performed with a Kaplan turbine in order to check theoretical results.

HIGH-SPEED WIND-TUNNEL TESTS OF A 1/78-SCALE MODEL OF THE LOCKHEED YP-80A AIRPLANE. Robert N. Olson and Leslie F. Lawrence. May 28, 1948. 52p. diagrs., photos. (NACA RM A7L24) (Declassified from Confidential, 10/12/54)

This report contains the results of a high-speed wind-tunnel investigation of a 1/78-scale model of the Lockheed YP-80A airplane, including a comparison of the relative aerodynamic characteristics of the 1/78-scale model, a 1/3-scale model, and a full-scale YP-80A airplane. Also included are the longitudinal stability and control characteristics of the 1/78-scale model with 0° and 45° leading-edge sweepback of the horizontal and vertical tail surfaces.

NACA RM L51K29

PROPELLER LIFT AND THRUST DISTRIBUTION FROM WAKE SURVEYS OF STAGNATION CONDITIONS. Robert E. Davidson. January 1952. 19p. diagrs. (NACA RM L51K29) (Declassified from Confidential, 10/12/54)

This paper gives formulas for propeller lift and thrust distribution in terms of wake-survey measurements of stagnation pressure rise through the propeller. Substantiative data are also included.

NACA RM L51L06

PROPELLER INDUCED ANGLES OF ATTACK AND SECTION ANGLES OF ATTACK FOR THE NACA 10-(3)(066)-03, 10-(3)(049)-03, 10-(3)(090)-03, 10-(5)(066)-03, AND 10-(0)(066)-03 PROPELLERS. William B. Igoe and Robert E. Davidson. May 1952. 80p. diagrs., 10 tabs. (NACA RM L51L06) (Declassified from Confidential, 10/12/54)

This paper presents the results of an induced angle-of-attack calculation using a method applicable to a propeller with arbitrary circulation distribution. Tables of induced angles of attack and section angles of attack and curves of wake-survey results are presented for the NACA 10-(3)(066)-03, 10-(3)(049)-03, 10-(3)(090)-03, 10-(5)(066)-03, and 10-(0)(066)-03 propellers. A brief description of the method of calculating propeller induced angles of attack is given.

NACA RM L51L28

THE EFFECT OF BLADE-SECTION CAMBER ON THE STATIC CHARACTERISTICS OF THREE NACA PROPELLERS. John H. Wood and John M. Swihart. April 1952. 40p. diagrs., photos. (NACA RM L51L28) (Declassified from Confidential, 10/12/54)

This paper contains the effect of blade-section camber on the static characteristics of the NACA 10-(0)(066)-03, 10-(3)(066)-03, and 10-(5)(066)-03 propellers (design lift coefficients of 0, 0.3, and 0.5, respectively). Blade angles from 0° to 16° were tested over a tip Mach number range from 0.28 to 1.02. The results indicate that the use of camber in the propeller design offers advantages in propeller performance and increases in stall-flutter speed at zero advance.

NACA RM L52A03

HINGE-MOMENT AND OTHER AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF A QUARTER-SPAN SPOILER ON A TAPERED 45° SWEPTBACK WING OF ASPECT RATIO 3. Joseph E. Fikes. February 1952. 22p. diagrs., photo. (NACA RM L52A03) (Declassified from Confidential, 10/12/54)

Lift, drag, pitching moment, rolling moment, yawing moment, and spoiler hinge moment were obtained at transonic speeds by testing in the high velocity field over a reflection plane on the side wall of the Langley high-speed 7- by 10-foot tunnel on a wing having a quarter-chord sweepback of 45.58°, an aspect ratio of 3, a taper ratio of 0.5, and an NACA 64A010 section employing an inboard quarter-span plug spoiler. The investigation was made over a limited projection and angle-of-attack range from a Mach number of 0.70 to 1.10.

NACA RM L52A09

EFFECT OF CURRENT DESIGN TRENDS ON AIRPLANE SPINS AND RECOVERIES. Anshal I. Neihouse. January 1952. 6p. diagrs. (NACA RM L52A09) (Declassified from Confidential, 10/12/54)

Charts are presented which indicate that, owing to design of airplanes for transonic and supersonic flight, a wide range of mass distribution of the airplane is possible with accompaning effects upon the nature of the spin and upon the requirements for recovery.

NACA RM L52A11

PRELIMINARY INVESTIGATION OF CONTROL CHARACTERISTICS AT TRANSONIC SPEEDS OF A TAPERED 45° SWEPTBACK WING OF ASPECT RATIO 3 HAVING A HORN-BALANCED FULL-SPAN CONTROL. John G. Lowry and Joseph E. Fikes. April 1952. 22p. diagrs., photo. (NACA RM L52A11) (Declassified from Confidential, 10/12/54)

An experimental investigation was made at transonic speeds by testing in the high-velocity field over a sidewall reflection plane to determine hinge-moment and effectiveness characteristics of a horn-balanced control on an aspect-ratio 3, 45° sweptback wing. Lift, rolling moments, and control hinge moments were obtained through a limited angle-of-attack and control-deflection range from Mach numbers 0.70 to 1.10.

NACA RM L52A14

PRELIMINARY INVESTIGATION OF THE DRAG CHARACTERISTICS OF THE NACA RM-10 MISSILE AT MACH NUMBERS OF 1.40 AND 1.59 IN THE LANGLEY 4- BY 4-FOOT SUPERSONIC TUNNEL. Lowell E. Hasel, Archibald R. Sinclair and Clyde V. Hamilton, April 1952. 49p. diagrs., photos, 3 tabs. (NACA RM L52A14) (Declassified from Confidential, 10/12/54)

A 0.287-scale model of the RM-10 has been tested in the Langley 4- by 4-foot supersonic tunnel at Mach numbers of 1.59 and 1.40. Drag data were obtained from a conventional sting-supported model and from a wire-supported model. Base drag, skin-friction drag, forebody pressure drag, fin drag, and fin interference drag are discussed. The data at a Mach number of 1.59 are compared with that from other facilities.

NACA RM L52A17

ERROR IN AIRSPEED MEASUREMENT DUE TO STATIC-PRESSURE FIELD AHEAD OF AN OPEN-NOSE AIR-INLET MODEL AT TRANSONIC SPEEDS. Thomas C. O'Bryan. March 1952. 17p. diagrs., photos. (NACA RM L52A17) (Declassified from Confidential, 10/12/54)

Contains measurements of the static-pressure coefficient at several distances ahead of an open-nose air-inlet body at zero angle of attack, in the transonic speed range, by the NACA wing-flow method. Measurements are presented to show the effect of inlet-velocity ratio on the static pressure ahead of the inlet. Comparison of the experimental variation of the static-pressure coefficient ahead of the inlet is made with incompressible theory. Calculations are presented to show the effect of changing inlet geometry on the static-pressure coefficient ahead of the inlets.

NACA RM L52A22

THE CALCULATION OF CERTAIN STATIC AEROELASTIC PHENOMENA OF WINGS WITH TIP TANKS OR BOOM-MOUNTED LIFTING SURFACES. Franklin W. Diederich and Kenneth A. Foss. August 1952. 55p. diagrs., 2 tabs. (NACA RM L52A22) (Declassified from Confidential, 10/12/54)

A method is presented for calculating static aeroelastic phenomena of wings with concentrated aerodynamic forces at the tip. Some static aeroelastic characteristics of an unswept wing with a tip tank and of a sweptback wing with several boom-mounted lifting surface configurations have been calculated. These calculations indicate that such a lifting surface merits consideration as a device for relieving adverse aeroelastic effects.

NACA RM L52A23

PRELIMINARY INVESTIGATION AT TRANSONIC SPEEDS OF THE EFFECT OF BALANCING TABS ON THE HINGE-MOMENT AND OTHER AERODYNAMIC CHARACTERISTICS OF A FULL-SPAN FLAP ON A TAPERED 45° SWEPTBACK WING OF ASPECT RATIO 3. Vernard E. Lockwood and Joseph E. Fikes. April 1952. 27p. diagrs., photo., (NACA RM L52A23) (Declassified from Confidential, 10/12/54)

An experimental investigation was performed at transonic speeds in the high-velocity-flow field over a reflection plane in the Langley high-speed 7- by 10-foot tunnel to determine the balancing characteristics of an inset, an attached, and a detached tab on an aspect-ratio 3, 45° sweptback wing. Lift, rolling moments, and flap hinge moments were obtained through a range of angles of attack from 0° to 16° and a Mach number range from 0.7 to 1.1. Data are presented as parameters of the flap and tab.

NACA RM L52A25

LOW-SPEED STABILITY CHARACTERISTICS OF A COMPLETE MODEL WITH A WING OF W PLAN FORM. Edward C. Polhamus and Robert E. Becht. April 1952. 27p. diagrs., photo., tab. (NACA RM L52A25) (Declassified from Confidential, 10/12/54)

An investigation was conducted to determine the low-speed static longitudinal and lateral stability characteristics of a complete model equipped with a W wing of aspect ratio 6, taper ratio 0.6, and panel sweep angles of 45°. Included in the investigation are exploratory tests made in an attempt to delay the early separation in the wing-panel junctures by use of fences, vortex generators, and chord extensions.

NACA RM L52B11

INVESTIGATION OF THE HYDRODYNAMIC STABILITY AND RESISTANCE OF TWO STREAMLINE FUSELAGES. Bernard Weinflash and Charles L. Shuford, Jr. April 1952. 32p. diagrs., photos., tab. (NACA RM L52B11) (Declassified from Confidential, 10/12/54)

An investigation of a dynamic model was made to determine the effects of hull form, gross load, and aerodynamic trimming moments on the trim limits, trim, hydrodynamic moment, hydrodynamic resistance, total resistance, and rise of two streamline fuselage configurations modified by chine strips.

NACA RM L52B13

EFFECTS OF SOME PRIMARY VARIABLES OF RECTANGULAR VORTEX GENERATORS ON THE STATIC-PRESSURE RISE THROUGH A SHORT DIFFUSER. E. Floyd Valentine and Raymond B. Carroll. May 1952. 32p. diagrs., photo., tab. (NACA RM L52B13) (Declassified from Confidential, 10/12/54)

An investigation was made of a 2:1 area ratio diffuser of length equal to the inlet diameter with separate variation of several basic parameters for simple nontwisted rectangular vortex generators over a considerable range of inlet-boundary-layer thickness. Optimum values from the standpoint of static pressure rise were determined for angle of attack, spacing, aspect ratio, and span-to-inlet boundary-layer thickness. The static-pressure rise obtainable by conforming to these findings is given over the range of inlet-boundary-layer thickness.

NACA RM L52B15a

AN INVESTIGATION OF LONGITUDINAL CONTROL CHARACTERISTICS OF A WING-TIP CONTROL SURFACE ON A SWEPTBACK WING AT TRANSONIC SPEEDS BY THE NACA WING-FLOW METHOD. James P. Trant, Jr. June 1952. 23p. diagrs., photos., tab. (NACA RM L52B15a) (Declassified from Confidential, 10/12/54)

Longitudinal control effectiveness of a full-chord wing-tip control on a wing having 35° sweepback 12 percent thickness perpendicular to the quarter-chord line, an aspect ratio of 3.01, and a taper ratio of 0.605 was determined by the NACA wing-flow method at Mach numbers from about 0.65 to 1.1. Measurements were made of normal force, pitching moment, hinge moment, and angle of attack for three control deflections. One control deflection was also tested with an end plate attached to the root chord of the control surface.

NACA RM L52B18

THE EFFECTS ON THE AERODYNAMIC CHARACTERISTICS OF VARYING THE WING THICKNESS RATIO OF A TRIANGULAR WING-BODY CONFIGURATION AT TRANSONIC SPEEDS FROM TESTS BY THE NACA WING-FLOW METHOD. Albert W. Hall and James M. McKay. April 1952. 27p. diagrs., photo., 2 tabs. (NACA RM L52B18) (Declassified from Confidential, 10/12/54)

Tests were made by the NACA wing-flow method at Mach numbers from 0.75 to 1.07 to determine the aerodynamic characteristics of three triangular wing-fuselage models which differed only in wing thickness-chord ratio. All three wings had an aspect ratio of 2.31 with 6-, 9-, and 12-percent-thick biconvex sections and the fuselage had a fineness ratio of 12. Measurements were made of normal force, chord force, and pitching moment for various angles of attack. The test Reynolds number was 1.5×10^6.

NACA RM L52B25

EFFECTS OF HORIZONTAL-TAIL POSITION AND ASPECT RATIO ON LOW-SPEED STATIC LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 60° TRIANGULAR-WING MODEL HAVING TWIN TRIANGULAR ALL-MOVABLE TAILS. Byron M. Jaquet. May 1952. 45p. diagrs., photos. (NACA RM L52B25) (Declassified from Confidential, 10/12/54)

Presents results of a low-speed investigation made in Langley stability tunnel to determine effects of horizontal tail position and aspect ratio on low-speed static longitudinal stability and control characteristics of a 60° triangular-wing model having twin-triangular-all-movable tails. All the force tests were made at a Mach number of 0.17 and a Reynolds number of 2.06×10^6. Comparison of results for single and twin tails are made.

NACA RM L52B26

FLIGHT MEASUREMENTS OF THE EFFECTS OF SURFACE CONDITION ON THE SUPERSONIC DRAG OF FIN-STABILIZED PARABOLIC BODIES OF REVOLUTION. H. Herbert Jackson. May 1952. 17p. diagrs., photos. (NACA RM L52B26) (Declassified from Confidential, 10/12/54)

Some measurements of the effects of various types of surface roughness on total drag and base drag were obtained on bodies of revolution in free flight. The Mach number and Reynolds number ranges varied from 0.80 to 2.2 and 15×10^6 to 75×10^6, respectively. The experimental drag coefficients of models having wavy surfaces, sand-coated surfaces, and pitted surfaces are compared with the drag coefficients of smooth models of the same configurations.

NACA RM L52C24

SKIN-FRICTION DRAG AND BOUNDARY-LAYER TRANSITION ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT A MACH NUMBER OF 1.6 IN THE LANGLEY 4- BY 4-FOOT SUPERSONIC PRESSURE TUNNEL. K. R. Czarnecki and Jack E. Marte. May 1952. 24p. diagrs., photos. (NACA RM L52C24) (Declassified from Confidential, 10/12/54)

There are presented the results of an investigation at $M = 1.6$ and over a Reynolds number range from 2×10^6 to 40×10^6 of the skin-friction drag and boundary-layer transition of a body of revolution (NACA RM-10). The results are compared with other available experimental data and with theory.

NACA RM L52C27

AN APPLICATION OF THE ROCKET-PROPELLED-MODEL TECHNIQUE TO THE INVESTIGATION OF LOW-LIFT BUFFETING AND THE RESULTS OF PRELIMINARY TESTS. Homer P. Mason and William N. Gardner. September 1952. 19p. diagrs., photos. (NACA RM L52C27) (Declassified from Confidential, 10/12/54)

An application of the rocket-propelled-model technique for the investigation of low-lift buffeting is presented, together with data obtained from three preliminary tests by this technique. A correlation between low-lift buffeting, wing dropping, and changes of trim normal force is shown.

NACA RM L52D08a

SMALL-SCALE TRANSONIC INVESTIGATION OF THE EFFECTS OF PARTIAL-SPAN LEADING-EDGE CAMBER ON THE AERODYNAMIC CHARACTERISTICS OF A 50° 38' SWEPTBACK WING OF ASPECT RATIO 2.98. William J. Alford, Jr. and Andrew L. Byrnes, Jr. June 1952. 28p. diagrs., photo., tab. (NACA RM L52D08a) (Declassified from Confidential, 10/12/54)

An investigation of two semispan wings having the same plan form was made in the Langley high-speed 7- by 10-foot tunnel over a Mach number range from 0.70 to 1.10 and a mean-test Reynolds number range from 745,000 to 845,000 to determine the effects of partial-span leading-edge camber on the aerodynamic characteristics of a sweptback wing. This paper presents the results of the wing-alone and wing-fuselage configurations with the wing quarter-chord line sweptback 50° 38' taper ratio 0.45, and NACA 64A-series airfoil sections tapered in thickness ratio. Lift, drag, pitching moment, and root-bending moment were obtained for all configurations.

NACA RM L52D15

A PRELIMINARY INVESTIGATION OF THE STATIC AND DYNAMIC LONGITUDINAL STABILITY OF A GRUMBERG HYDROFOIL SYSTEM. Norman S. Land, Derrill B. Chambliss and William W. Petynia. September 1952. 48p. diagrs., photos. (NACA RM L52D15) (Declassified from Confidential, 10/12/54)

A preliminary investigation was made in order to determine the static and dynamic longitudinal stability characteristics and the force characteristics of the Grunberg hydrofoil system, comprising a main lifting hydrofoil and planing-surface stabilizers. The static stability of the system was determined for several locations of the center of gravity. In smooth water the response to a sudden distrubance was observed. The behavior in waves of various lengths was observed at several speeds, moments of inertia, and locations of the center of gravity. The effects of gross load, hydrofoil and stabilizer incidence, speed, and center-of-gravity location on the lift-drag ratio were determined.

NACA RM L52D21

EFFECTS OF PLAN FORM, AIRFOIL SECTION, AND ANGLE OF ATTACK ON THE PRESSURES ALONG THE BASE OF BLUNT-TRAILING-EDGE WINGS AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Kennith L. Goin. September 1952. 52p. photos., diagrs. (NACA RM L52D21) (Declassified from Confidential, 10/12/54)

Base pressures were measured at angles of attack of 0° to 15° on two groups of untapered wings of aspect ratio 2.7, the first group being unswept and the second group having 45° of sweepback. Each group included airfoil sections with maximum thickness ratios of 3 to 10 percent and with varying amounts of trailing-edge bluntness. Also included in the investigation to indicate additional effects of wing plan form were a 45° delta wing and a rectangular wing of aspect ratio 5. All wings were tested with fixed transition at Reynolds numbers of between 1×10^6 and 2×10^6.

NACA RM L52D23a

A THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE LIFT AND DRAG CHARACTERISTICS OF A HYDROFOIL AT SUBCRITICAL AND SUPERCRITICAL SPEEDS. Kenneth L. Wadlin, Charles L. Shuford, Jr. and John R. McGehee. July 1952. 53p. diagrs., photo., tab. (NACA RM L52D23a) (Declassified from Confidential, 10/12/54)

A theoretical and experimental investigation was made of the effect of the free-water surface and rigid boundaries on the lift and drag of an aspect-ratio-10 hydrofoil at both subcritical and supercritical speeds. Approximate theoretical solutions for the effect of the free-water surface and rigid boundaries on lift and drag at supercritical speeds were developed. An approximate theoretical solution for the effect of these boundaries on drag at subcritical speeds was also presented. The agreement between theory and experiment at both supercritical and subcritical speeds is satisfactory for engineering calculations of hydrofoil characteristics from aerodynamic data.

NACA RM L52D25

CONTROL CHARACTERISTICS AT TRANSONIC SPEEDS OF A LINKED FLAP AND SPOILER ON A TAPERED 45° SWEPTBACK WING OF ASPECT RATIO 3. Vernard E. Lockwood and Joseph E. Fikes. July 1952. 24p. diagrs., photo. (NACA RM L52D25) (Declassified from Confidential, 10/12/54)

Lift, drag, pitching-moment, rolling-moment, yawing-moment, and hinge-moment characteristics of the model were obtained at transonic speeds by testing in the high-velocity field over a reflection plane on the side wall of the Langley high-speed 7- by 10-foot tunnel. The wing had a quarter-chord line sweepback of 45.58°, an aspect ratio of 3, a taper ratio of 0.5, and was approximately 7.6 percent thick. A quarter-span plug-type spoiler which was linked to rotate with the flap in the same direction was employed as a control-balancing device. The investigation was made over a limited projection and angle-of-attack range from a Mach number of 0.70 to 1.10.

NACA RM L52D30

PRESSURE DISTRIBUTIONS ON BODIES OF REVOLUTION AT SUBSONIC AND TRANSONIC SPEEDS. Richard I. Cole. July 1952. 47p. diagrs., photos., tab. (NACA RM L52D30) (Declassified from Confidential, 10/12/54)

Pressure distributions along the slender body and along prolate spheroids of fineness ratio 3 to 20 are compared at subsonic and transonic speeds with estimates at angles of attack up to 20°. The comparisons showed that the pressure distributions along the bodies can be predicted with fair accuracy.

NACA RM L52E12

SMALL-SCALE TRANSONIC INVESTIGATION OF THE EFFECTS OF FULL-SPAN AND PARTIAL-SPAN LEADING-EDGE FLAPS ON THE AERODYNAMIC CHARACTERISTICS OF A 50° $38'$ SWEPTBACK WING OF ASPECT RATIO 2.98. Kenneth P. Spreemann and William J. Alford, Jr. July 1952. 31p. diagrs., photo. (NACA RM L52E12) (Declassified from Confidential, 10/12/54)

An investigation was made in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.70 to 1.10 to determine the effects of a number of full-span and partial-span leading-edge-flap deflections on the aerodynamic characteristics of a semi-span model with the quarter-chord line sweptback 50° $38'$, aspect ratio 2.98, taper ratio 0.45, and NACA 64A series airfoil sections tapered in thickness ratio. Lift, drag, pitching moment, and bending moment were obtained for all configurations.

NACA RM L52E19

A THEORETICAL INVESTIGATION OF THE EFFECT OF A TARGET SEEKER SENSITIVE TO PITCH ATTITUDE ON THE DYNAMIC STABILITY AND RESPONSE CHARACTERISTICS OF A SUPERSONIC CANARD MISSILE CONFIGURATION. Ordway B. Gates, Jr. and Albert A. Schy. August 1952. 54p. diagrs., photo., tab. (NACA RM L52E19) (Declassified from Confidential, 10/12/54)

A theoretical investigation is presented of the longitudinal dynamic characteristics of an automatically stabilized supersonic canard missile equipped with a target seeker sensitive to pitch attitude. Effects of seeker gain, time delay, and nonlinearities, which include various dead spots in the target seeker, are considered. The results indicate that satisfactory stability and response characteristics may be obtained for the configuration considered subsequent to command or regulatory inputs but a dead spot in the target seeker causes undesirable steady-state errors in pitch attitude.

NACA RM L52F16

LATERAL-CONTROL INVESTIGATION AT TRANSONIC SPEEDS OF RETRACTABLE SPOILER AND PLUG-TYPE SPOILER-SLOT AILERONS ON A TAPERED 60° SWEPTBACK WING OF ASPECT RATIO 2. TRANSONIC-BUMP METHOD. Alexander D. Hammond and James M. Watson. August 1952. 19p. diagrs. (NACA RM L52F16) (Declassified from Confidential, 10/12/54)

Results and discussion of a lateral-control investigation of retractable spoiler and plug-type spoiler-slot ailerons on a wing with 60° sweepback of the quarter-chord line, aspect ratio 2, taper ratio 0.6, and an NACA 65A006 airfoil section are presented. Data were obtained through an angle-of-attack range of -2° to 18°, a projection range of -0.056 to 0.045 chord, and a Mach number range of 0.619 to 1.167. The plug-type spoiler-slot aileron was more effective in producing roll than the retractable spoiler aileron, particularly at the high angles of attack below the speed of sound.

NACA RM L52F24

CALIBRATION OF A COMBINED PITOT-STATIC TUBE AND VANE-TYPE FLOW ANGULARITY INDICATOR AT TRANSONIC SPEEDS AND AT LARGE ANGLES OF ATTACK OR YAW. Albin O. Pearson and Harold A. Brown. September 1952. 25p. diagrs., photos. (NACA RM L52F24) (Declassified from Confidential, 10/12/54)

The calibration of a combination pitot-static tube and vane-type flow-angularity indicator is presented for a Mach number range of approximately 0.60 to 1.11, an angle-of-attack range of -10° to 25°, and an angle-of-yaw range of -20° to 20°.

NACA RM L52G03

THE EFFECT OF VARIOUS AERODYNAMIC BALANCES ON THE LOW-SPEED LATERAL-CONTROL AND HINGE-MOMENT CHARACTERISTICS OF A 0.20-CHORD PARTIAL-SPAN OUTBOARD AILERON ON A WING WITH LEADING EDGE SWEPT BACK 51.3°. Alexander D. Hammond. September 1952. 40 p. diagrs., photo., tab. (NACA RM L52G03) (Declassified from Confidential, 10/12/54)

A wind-tunnel investigation at low speeds was made to determine the lateral-control and hinge-moment characteristics of an unsealed, plain-radius-nose, 20-percent-chord, flat-sided, partial-span outboard aileron equipped with either an overhang, a paddle, or a spoiler balance on a wing with leading edge swept back 51.3°, aspect ratio of 3.05, taper ratio of 0.49, and NACA 65_1-012 airfoil sections perpendicular to the 55.6-percent chord line.

NACA RM L52G08

HINGE-MOMENT AND CONTROL-EFFECTIVENESS CHARACTERISTICS OF AN OUTBOARD FLAP WITH AN OVERHANG NOSE BALANCE ON A TAPERED 35° SWEPTBACK WING OF ASPECT RATIO 4. TRANSONIC-BUMP METHOD. Robert F. Thompson and William C. Moseley, Jr. August 1952. 51p. diagrs. (NACA RM L52G08) (Declassified from Confidential, 10/12/54)

Lift, pitching-moment, rolling-moment, and flap hinge-moment coefficients were obtained through the transonic speed range on a wing having a quarter-chord sweepback of 35°, an aspect ratio 4, a taper ratio of 0.6, and an NACA 65A006 airfoil section parallel to free stream. The wing had a 30-percent-chord 0.43-span outboard flap-type control with a 22-percent-flap-chord overhang nose balance. The investigation was made through an angle-of-attack range of -6° to 16°, a Mach number range from 0.6 to 1.10, and a range of flap deflections which varied from about ±24° at a Mach number of 0.60 to ±12° at a Mach number of 1.10.

NACA RM L52G10

LOW-SPEED LATERAL-CONTROL INVESTIGATION OF A FLAP-TYPE SPOILER AILERON WITH AND WITHOUT A DEFLECTOR AND SLOT ON A 6-PERCENT-THICK, TAPERED, 45° SWEPTBACK WING OF ASPECT RATIO 4. James M. Watson. September 1952. 11p. diagrs. (NACA RM L52G10) (Declassified from Confidential, 10/12/54)

Results are presented of an investigation to determine the lateral-control characteristics of a deflector and slot arrangement in conjunction with a flap-type spoiler aileron on a 6-percent-thick wing with 45° sweepback of the quarter-chord line, an aspect ratio of 4, and a taper ratio of 0.6. Data were obtained through a range of angle of attack from -26° to 60°, projections of 0 and 0.05 chord for both the flap-type spoiler aileron and the deflector. The spoiler-deflector-slot combination was more effective than the spoiler alone in producing rolling moment.

NACA RM L52G16

TESTS OF A CENTERING SPRING USED AS AN ARTIFICAL FEEL DEVICE ON THE ELEVATOR OF A FIGHTER AIRPLANE. James J. Adams and James B. Whitten. September 1952. 18p. diagrs., photo., tab. (NACA RM L52G16) (Declassified from Confidential, 10/12/54)

Tests were made of a centering spring, which gave no variation of force gradient with impact pressure used as an artificial feel device for the elevator of a Chance Vought F4U-4B airplane equipped with power controls. The centering spring was unsatisfactory because of the large stick force encountered in landing. When a preloaded spring was included in the system to relieve the large landing force, and a bobweight was added to increase the force per g, the system satisfied the minimum handling-qualities requirements, but was still considered to provide insufficient centering tendency at high speeds.

NACA RM L52G22

THE EFFECTS OF CAMBER AND LEADING-EDGE-FLAP DEFLECTION ON THE PRESSURE PULSATIONS ON THIN RIGID AIRFOILS AT TRANSONIC SPEEDS. Milton D. Humphreys and John D. Kent. October 1952. 26p. diagrs., photos., tab. (NACA RM L52G22) (Declassified from Confidential, 10/12/54)

The effect of camber and leading-edge-flap deflection on the pressure pulsations on thin rigid airfoils at Mach numbers from 0.5 to 1.0 has been investigated for 6-percent-thick NACA 64A-series airfoils. The results of the pressure-pulsation investigation on these airfoils indicated that at the higher normal-force coefficients, either camber or leading-edge-flap deflection reduced the pressure-pulsation level over the entire chord.

NACA RM L52G24

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF VORTEX GENERATORS ON THE MAXIMUM LIFT OF A 6-PERCENT-THICK SYMMETRICAL CIRCULAR-ARC AIRFOIL SECTION. William J. Bursnall. October 1952. 16p. diagrs., 2 tabs. (NACA RM L52G24) (Declassified from Confidential, 10/12/54)

The results of an experimental investigation of the effectiveness of several configurations of vortex generators in increasing the maximum lift of a 6-percent-thick symmetrical circular-arc airfoil section indicated that none of the configurations employed substantially increased the maximum lift.

NACA RM L52G25

A PRELIMINARY INVESTIGATION OF SHOCK-WAVE REFLECTIONS IN A SMALL CLOSED BALLISTIC RANGE WITH VARIOUS TYPES OF WALLS. A. P. Sabol. September 1952. 21p. photos., diagrs. (NACA RM L52G25) (Declassified from Confidential, 10/12/54)

The intensity of reflections from walls of shock waves, which were created by a bullet traveling near the speed of sound, was observed by shadow and schlieren methods. Results indicated that reflected waves are greatly reduced by the use of a wall material having good sound-absorbing characteristics, or by specially designed wall configurations.

NACA RM L52G31a

EFFECT OF THICKNESS, CAMBER, AND THICKNESS DISTRIBUTION ON AIRFOIL CHARACTERISTICS AT MACH NUMBERS UP TO 1.0. Bernard N. Daley and Richard S. Dick. October 1952. 76p. photos., diagrs., tab. (NACA RM L52G31a) (Declassified from Confidential, 10/12/54)

A modified open-throat-type wind tunnel developed for the purpose of obtaining two-dimensional-airfoil data at Mach numbers near 1.0 is presented and discussed. Tests of a group of related NACA airfoil sections varying in maximum thickness, design lift coefficient, and thickness distribution have been conducted in this wind tunnel at Mach numbers of 0.3 to about 1.0, and at corresponding Reynolds numbers from 0.7×10^6 to 1.6×10^6. Normal-force, drag, and moment coefficients are presented, together with representative schlieren photographs and pressure-distribution diagrams.

NACA RM L52H04

HEAT TRANSFER AND SKIN FRICTION FOR TURBULENT BOUNDARY LAYERS ON HEATED OR COOLED SURFACES AT HIGH SPEEDS. Coleman duP. Donaldson. October 1952. 20p. diagr., 3 tabs. (NACA RM L52H04) (Declassified from Confidential, 10/12/54)

The method presented in NACA TN 2692 for evaluating the skin friction of a turbulent boundary layer in compressible flow on an insulated surface is extended to evaluate the turbulent skin friction and heat transfer in compressible flow on a surface which is heated or cooled. The results of this analysis are in good agreement with the heat transfers measured in flight on the NACA RM-10 missile up to Mach number of 3.8.

NACA RM L52H07

INVESTIGATION OF THREE TAPERED 45° SWEPTBACK CAMBERED AND TWISTED WINGS COVERING A SIMULTANEOUS VARIATION IN ASPECT RATIO AND THICKNESS RATIO AND OF ONE RELATED SYMMETRICAL WING AT TRANSONIC SPEEDS BY THE WING-FLOW METHOD. Harold I. Johnson. March 1953. 55p. diagrs., photos., 2 tabs. (NACA RM L52H07) (Declassified from Confidential, 10/12/54)

An investigation at transonic speeds was made to study the effects of aspect ratio of a 45° sweptback wing for the case where thickness ratio is varied in a logical manner with aspect ratio. The effects of camber and twist were also investigated. The Mach numbers ranged from 0.65 to 1.17 and the Reynolds numbers ranged from 230,000 to 620,000. Results showed that the lowest-aspect-ratio, thinnest wing tested had the best aerodynamic characteristics in

all important respects. The addition of camber and twist reduced the maximum lift-drag ratios over most of the speed range tested but increased the maximum lift coefficient at all speed.

NACA RM L52H11

A STUDY OF THE FLOW FIELD BEHIND THE TRIANGULAR HORIZONTAL TAIL OF A CANARD AIRPLANE AT APPROXIMATELY THE VERTICAL-TAIL LOCATION BY MEANS OF A TUFT GRID. Joseph L. Johnson, Jr. October 1952. 18p. diagrs., tab. (NACA RM L52H11) (Declassified from Confidential, 10/12/54)

An investigation of the flow field behind the horizontal triangular tail of a canard model by means of a tuft grid placed at approximately the vertical-tail location (about 6.0 horizontal-tail root chords behind the horizontal tail) indicated that trailing vortices from the horizontal tail produced a sidewash field over the model which probably accounted for the variation in the static directional stability and damping-in-yaw characteristics of canard models reported in previous investigations.

NACA RM L52H20

A TRANSONIC INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF PLATE- AND BELL-TYPE OUTLETS FOR AUXILIARY AIR. William J. Nelson and Paul E. Dewey. September 1952. 25p. diagrs., photos. (NACA RM L52H20) (Declassified from Confidential, 10/12/54)

The aerodynamic characteristics of several plate-type and bell-mouthed outlets representative of current design practice have been investigated at Mach numbers from 0.7 to 1.3. These data show that the effect of an external stream on the discharge coefficient of such outlets is determined primarily by the rate of discharge relative to the free-jet flow rate. For outlets of the types tested, low-speed data may probably be applied at transonic Mach numbers if the free-jet characteristics of the outlet are first corrected for the effects of Reynolds number and Mach number on the discharge characteristics of the outlet discharging into infinite space. Total-pressure surveys through the jet wake are compared at Mach numbers of 0.7, 1.1, and 1.3 for the different outlets investigated. Static-pressure distribution in the vicinity of circular outlets is shown for several Mach numbers and discharge rates.

NACA RM L52H21

INVESTIGATION OF THE VARIATION WITH REYNOLDS NUMBER OF THE BASE, WAVE, AND SKIN-FRICTION DRAG OF A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT MACH NUMBERS OF 1.62, 1.93, AND 2.41 IN THE LANGLEY 9-INCH SUPERSONIC TUNNEL. Eugene S. Love, Donald E. Coletti and August F. Bromm, Jr. October 1952. 62p. diagrs., photos., (NACA RM L52H21) (Declassified from Confidential, 10/12/54)

Results are presented from an investigation at M = 1.62, 1.93, and 2.41 of the variation with Reynolds number of the base, wave, and skin-friction drag of a parabolic body of revolution (NACA RM-10). Comparisons are made with theory and other experimental data. An empirical expression relating the Reynolds number of transition to Mach number is presented as well as an explanation of the behavior of base pressure with varying Reynolds number.

NACA RM L52I02

INVESTIGATION AT HIGH AND LOW SUBSONIC MACH NUMBERS OF TWO SYMMETRICAL 6-PERCENT-THICK AIRFOIL SECTIONS DESIGNED TO HAVE HIGH MAXIMUM LIFT COEFFICIENTS AT LOW SPEEDS. Nicholas J. Paradiso. October 1952. 37p. diagrs., photo., 2 tabs. (NACA RM L52I02) (Declassified from Confidential, 10/12/54)

Results are presented of an investigation at both high and low subsonic Mach numbers of two newly derived symmetrical 6-percent-thick airfoil sections which are of a family of airfoil sections designed for high maximum lift at low subsonic speeds. As compared to previously tested sections of this family, the sections of this investigation have less blunt leading edges. Included are results for Reynolds numbers up to 9×10^6 and for two locations of surface roughness.

NACA RM L52I03

THRUST LOADING OF THE NACA 3-(3)(05)-05 EIGHT-BLADE DUAL-ROTATING PROPELLER AS DETERMINED FROM WAKE SURVEYS. Robert J. Platt, Jr. October 1952. 44p. diagrs., photo. (NACA RM L52I03) (Declassified from Confidential, 10/12/54)

Wake-survey measurements of the thrust loading of the NACA 3-(3)(05)-05 eight-blade dual-rotating propeller are presented to supplement the previously published force-test results for this propeller. The data cover a blade-angle range from 65° to 80°, measured at 0.75R, at forward Mach numbers from 0.35 to 0.925.

NACA RM L52I08

FORCE TESTS OF THREE THIN WINGS OF MODERATELY LOW ASPECT RATIO AT HIGH SUBSONIC MACH NUMBERS. Gareth H. Jordan. October 1952. 22p. diagrs. (NACA RM L52I08) (Declassified from Confidential, 10/12/54)

Results are presented of force tests made in the Langley 24-inch high-speed tunnel on three thin wings of moderately low aspect ratio at high subsonic Mach numbers to determine the effect of leading-edge shape and section profile on the aerodynamic characteristics. The range of angle of attack was from -2° to 8° and the range of Mach number was from 0.30 to about 0.90.

NACA RM L52I09

ANALYTICAL STUDY OF STATIC AND LOW-SPEED PERFORMANCE OF THIN PROPELLERS USING TWO-SPEED GEAR RATIOS TO OBTAIN OPTIMUM ROTATIONAL SPEEDS. Jean Gilman, Jr. November 1952. 52p. diagrs., 4 tabs. (NACA RM L52I09) (Declassified from Confidential, 10/12/54)

This paper presents methods of estimating the static and low-speed performance of thin propellers when operating at optimum rotational speeds. The importance, under certain conditions, of incorporating variable gearing is illustrated by specific examples. The effect of camber on static thrust is also investigated, and it is shown that thin propellers having moderately cambered blade sections can produce 15 to 20 percent more static thrust than propellers having symmetrical blade sections.

NACA RM L52K18a

A STUDY OF THE USE OF VARIOUS HIGH-LIFT DEVICES ON THE HORIZONTAL TAIL OF A CANARD AIRPLANE MODEL AS A MEANS OF INCREASING THE ALLOWABLE CENTER-OF-GRAVITY TRAVEL. Joseph L. Johnson, Jr. January 1953. 25p. diagrs., 2 tabs. (NACA RM L52K18a) (Declassified from Confidential, 10/12/54)

This paper contains results of a low-speed power-off static longitudinal stability and control investigation to study the use of various high-lift devices on the horizontal tail of a canard airplane model as a means of increasing the allowable center-of-gravity travel.

NACA RM L52K28a

AVERAGE SKIN-FRICTION COEFFICIENTS FROM BOUNDARY-LAYER MEASUREMENTS ON A OGIVE-CYLINDER BODY IN FLIGHT AT SUPERSONIC SPEEDS. J. Dan Loposer. January 1953. 11p. diagrs., photo. (NACA RM L52K28a) (Declassified from Confidential, 10/12/54)

Boundary-layer measurements on a rocket-powered free-flight model to determine average skin-friction coefficients have been made on an ogive-cylinder body of fineness ratio 15.9. Average skin-friction coefficients were obtained for the body area ahead of the fins over a range of Mach number from 1.3 to 2.5 and over a range of Reynolds number from 90.3×10^6 to 162.9×10^6 (based on axial body length to the measurement station). Comparison of the experimental data with a flat-plate skin-friction theory by Van Driest showed good agreement.

NACA RM L52L02

A COMPARISON OF GUST LOADS MEASURED IN FLIGHT ON A SWEPT-WING AIRPLANE AND AN UNSWEPT-WING AIRPLANE. Jack Funk and Harry C. Mickleboro. June 1953. 16p. diagrs., 2 tabs. (NACA RM L52L02) (Declassified from Confidential, 10/12/54)

An unswept-wing airplane and a 35° swept-wing airplane were flown in rough air to investigate effects of sweep on gust loads and gust selectivity. The swept-wing airplane experienced lower loads in rough air than the unswept-wing airplane. The ratio of loads on the two airplanes was equal to the cosine of the angle of sweep and to the ratio of the lift-curve slopes from either low-speed wind-tunnel data or calculated from the empirical formula $\frac{6A \cos \Lambda}{A + 2 \cos^2 \Lambda}$, where A is aspect ratio and Λ is the angle of sweep. Only small differences were shown in the gust selectivity characteristics of the two airplanes.

NACA RM L52L09

WING AND FUSELAGE LOADS MEASURED IN FLIGHT ON THE NORTH AMERICAN B-45 AND F-82 AIRPLANES. Paul W. Harper. February 1953. 35p. diagrs., 4 tabs. (NACA RM L52L09) (Declassified from Confidential, 10/12/54)

Flight investigations were conducted to determine the wing and fuselage loads on the B-45 and F-82 airplanes by means of calibrated strain-gage installations at each wing- and tail-fuselage juncture. The tests covered a Mach number range of approximately 0.3 to 0.75. The aerodynamic loads measured for the B-45 airplane were substantially as predicted by theory, but the loads on the F-82 airplane were in disagreement with theory. A gradual outboard shift in wing center of pressure with increasing Mach number was noted for both airplanes.

NACA RM L52L11

EXPERIMENTAL INVESTIGATION OF THE FLOW FIELD BEHIND AN ASPECT-RATIO-10 HYDROFOIL NEAR THE WATER SURFACE. Arthur W. Carter and Roger V. Butler. February 1953. 31p. diagrs., photos., tab. (NACA RM L52L11) (Declassified from Confidential, 10/12/54)

An investigation was made at subcritical speeds of the flow field behind an aspect-ratio-10 hydrofoil operating at a depth below the free-water surface of 0.75 chord. The downwash and water surface profiles were measured behind the hydrofoil over a range of lateral and longitudinal positions of interest for tandem hydrofoil applications. The experimental data were compared with theoretical predictions based on two-dimensional flow.

NACA RM L52L22

FREE-FLIGHT-TUNNEL INVESTIGATION OF THE LOW-SPEED STABILITY AND CONTROL CHARACTERISTICS OF A MODEL HAVING A FUSELAGE OR RELATIVELY FLAT CROSS SECTION. John W. Paulson and Joseph L. Johnson, Jr. February 1953. 30p. diagrs., photo., tab. (NACA RM L52L22) (Declassified from Confidential, 10/12/54)

Results are presented of an experimental investigation in the Langley free-flight tunnel to determine the dynamic lateral stability and control characteristics of a model having a relatively flat cross-section fuselage. Tests were made with several vertical-tail configurations and with the leading-edge flap retracted and extended.

NACA RM L52L26a

EFFECTS OF ROUGHNESS AND REYNOLDS NUMBER ON THE NONLINEAR LIFT CHARACTERISTICS OF A WING WITH MODIFIED HEXAGONAL AIRFOIL SECTIONS. Milton A. Schwartzberg. February 1953. 18p. diagrs., photo. (NACA RM L52L26a) (Declassified from Confidential, 10/12/54)

Nonlinear lift characteristics of a low-aspect-ratio wing with modified hexagonal airfoil sections at low Reynolds numbers were observed at Mach numbers from 0.379 to 0.896. Effects of increased Reynolds numbers and of surface roughness on the linearity of the lift curves were investigated.

NACA RM L53A19

SOME TORSIONAL-DAMPING MEASUREMENTS OF LAMINATED BEAMS AS APPLIED TO THE PROPELLER STALL-FLUTTER PROBLEM. Atwood R. Heath, Jr. April 1953. 14p. diagrs., photos., tab. (NACA RM L53A19) (Declassified from Confidential, 10/12/54)

The structural damping in the torsion mode of vibration of a series of untwisted, laminated thin beams simulating propeller blades is presented. The number of laminations were varied, as well as the bonding material and the method of joining laminations. Application of the data to the calculation of the minimum flutter speed of thin propeller blades indicates that appreciable gains in the minimum flutter speed may be obtained for laminated blades using a Cycleweld bond.

NACA RM L53B19

WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF VARIOUS DORSAL-FIN AND VERTICAL-TAIL CONFIGURATIONS ON THE DIRECTIONAL STABILITY OF A STREAMLINED BODY OF TRANSONIC SPEEDS. TRANSONIC-BUMP METHOD. Harold S. Johnson and William C. Hayes. April 1953. 22p. diagrs., photo., tab. (NACA RM L53B19) (Declassified from Confidential, 10/12/54)

Yawing-moment coefficients were obtained for several dorsal-fin and vertical-tail configurations in combination with a streamlined body through a large angle-of-sideslip range and a Mach number range of 0.59 to 1.11. The results indicated that dorsal fins improved the directional stability characteristics of the body alone and the body—vertical-tail configuration. A ring tail was more effective at small angles of sideslip and less effective at large angles of sideslip than a tapered low-aspect-ratio vertical tail.

NACA RM L53C10

A PRELIMINARY INVESTIGATION OF AERODYNAMIC CHARACTERISTICS OF SMALL INCLINED AIR OUTLETS AT TRANSONIC MACH NUMBERS. Paul E. Dewey. April 1953. 21p. photos., diagrs. (NACA RM L53C10) (Declassified from Confidential, 10/12/54)

The aerodynamic characteristics of several outlets with inclined or curved axes discharging air into a transonic stream have been investigated. The data presented herein show the discharge coefficient of such outlets and static-pressure distribution in the vicinity of the outlets for several values of stream Mach number and discharge flow parameter. Tuft observations, showing the vortex formation caused by the outlet discharge from a perpendicular and an inclined outlet, are also presented.

NACA RM L53D21

MEASUREMENTS OF AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF AN UNSWEPT AND UNTAPERED NACA 65-009 AIRFOIL MODEL OF ASPECT RATIO 3 WITH 1/4-CHORD PLAIN FLAP BY THE NACA WING-FLOW METHOD. Harold I. Johnson. June 1953. 35p. diagrs., photo. (NACA RM L53D21) (Declassified from Confidential, (10/12/54)

Lift, pitching-moment, and hinge-moment data obtained from wing-flow tests of an unswept, untapered NACA 65-009 airfoil model of aspect ratio 3.01 equipped with 1/4-chord full-span plain flap are presented. Effects of flap gap and of roughness were investigated. The Mach number range of the tests was 0.65 to 1.10 and the Reynolds number range was 0.5×10^6 to 0.9×10^6.

NACA RM L53D30

CALCULATION OF AERODYNAMIC FORCES ON AN INCLINED DUAL-ROTATING PROPELLER. John L. Crigler and Jean Gilman, Jr. June 1953. 24p. diagrs. (NACA RM L53D30) (Declassified from Confidential, 10/12/54)

This paper presents a method of calculating the fluctuating aerodynamic forces on a dual-rotating propeller the thrust axis of which is inclined at an angle to the air stream. Sample calculations are made and the results are analyzed to show some of the effects encountered with this type of operation.

NACA RM L53E12

EFFECTS OF COMPRESSIBILITY AT MACH NUMBERS UP TO 0.8 ON INTERNAL-FLOW CHARACTERISTICS OF A COWLING-SPINNER COMBINATION EQUIPPED WITH AN EIGHT-BLADE DUAL-ROTATION PROPELLER. Gene J. Bingham and Arvid L. Keith, Jr. June 1953. 39p. diagrs., photos. (NACA RM L53E12) (Declassified from Confidential, 10/12/54)

An investigation has been conducted to study the effects of compressibility for Mach numbers up to 0.8 on the internal-flow characteristics of an NACA 1-series cowling-spinner combination equipped with a dual-rotation propeller. Two propellers having 24-percent-thick shank sections were studied; one had the propeller shanks extended to the spinner surface and the juncture sealed, and the other had a raised platform-type juncture with the gap required to allow blade-angle changes located outside of the spinner boundary layer. The effects of variations in inlet height and rate of internal compression on the internal-flow characteristics were also studied. Total- and static-pressure distributions and average impact pressure coefficients measured at the inlet and at a diffuser station are presented.

NACA RM L53E28a

INVESTIGATION AT TRANSONIC SPEEDS OF THE HINGE-MOMENT AND LIFT-EFFECTIVENESS CHARACTERISTICS OF A SINGLE FLAP AND A TANDEM FLAP ON A 60° DELTA WING. Delwin R. Croom and Harleth G. Wiley. July 1953. 16p. diagrs. (NACA RM L53E28a) (Declassified from Confidential, 10/12/54)

This paper presents the results of an investigation to determine the comparative hinge-moment and lift-effectiveness characteristics of a single flap and a tandem flap on a semispan 60° delta-wing model at transonic speeds by the transonic-bump method. The delta-wing model was a flat plate with beveled leading and trailing edges, a maximum thickness ratio of 0.045, 60° sweepback at the leading edge, a taper ratio of 0, and an aspect ratio of 2.31. Lift and hinge moments were obtained through a Mach number range of 0.60 to 1.11. The tandem flap had less variation of C_{h_δ} (hinge-moment coefficient per degree flap deflection) with Mach number than did the single flap and the lift effectiveness was only about 50 percent of that obtained with the single flap.

NACA RM L53F16a

LOW-SPEED INVESTIGATION OF THE LATERAL CONTROL CHARACTERISTICS OF THREE TIP AILERONS ON A 60° TRIANGULAR WING. Stanley M. Gottlieb. August 1953. 24p. diagrs., photo. (NACA RM L53F16a) (Declassified from Confidential, 10/12/54)

An investigation has been made at a Reynolds number of 9×10^6 and a Mach number of 0.15 of the lateral control characteristics of three wing-tip ailerons on a 6-percent-thick, 60° triangular-wing-fuselage combination. The controls consisted of two half-delta ailerons having areas equal to 0.077 and 0.138 times the wing-semispan area and a full-delta aileron having an area equal to 0.138 times the wing-semispan area. The tests, which included measurements of rolling moments, hinge moments, yawing moments, and lateral force, were made through ranges of angle of attack and deflection from -12° to 38° and from -20° to 20°, respectively.

NACA RM L53G08

INVESTIGATION TO DETERMINE EFFECTS OF RECTANGULAR VORTEX GENERATORS ON THE STATIC-PRESSURE DROP THROUGH A 90° CIRCULAR ELBOW. E. Floyd Valentine and Martin R. Copp. September 1953. 35p. diagrs., photos. (NACA RM L53G08) (Declassified from Confidential, 10/12/54)

An investigation was made of a constant-area, circular 90° elbow of mean radius or curvature equal to its diameter with several arrangements of simple, nontwisted, rectangular vortex generators. They were installed at the inlet and also at stations 15°, 30°, and 60° into the elbow. The effect of the vortex generators on the pressure drop measured between the inlet and a station 4 diameters downstream of the elbow is given for one inlet-boundary-layer thickness.

NACA RM L53G23

TRANSONIC AERODYNAMIC CHARACTERISTICS OF AN NACA 64A006 AIRFOIL SECTION WITH A 15-PERCENT-CHORD LEADING-EDGE FLAP. Milton D. Humphreys. September 1953. 44p. diagrs., photos. (NACA RM L53G23) (Declassified from Confidential, 10/12/54)

Two-dimensional airfoil section normal-force, drag, pitching-moment, flap normal-force, and hinge-moment characteristics obtained on an NACA 64A006 airfoil section equipped with a 15-percent-chord leading-edge flap are presented for Mach numbers from 0.5 to 1.0. The leading-edge flap effected a general improvement in the force characteristics at Mach numbers up to 0.8 by alleviating flow separation at high normal-force coefficients.

NACA RM L53G23a

THE EFFECT OF CONTROL-SURFACE-SERVO NATURAL FREQUENCY ON THE DYNAMIC PERFORMANCE CHARACTERISTICS OF AN ACCELERATION CONTROL SYSTEM APPLIED TO A SUPERSONIC MISSILE. Anthony L. Passera and Martin L. Nason. September 1953. 28p. diagrs., 3 tabs. (NACA RM L53G23a) (Declassified from Confidential, 10/12/54)

A theoreotical investigation is made to determine the effect of the natural frequency of a second-order control-surface servo upon the dynamic performance characteristics of a normal-acceleration control system with respect to accuracy of control and accumulator volume of flow and peak rate of volume flow for several missile scale sizes and flight conditions in response to a step-input command. This paper seeks a compromise value of natural frequency that yields a control system with moderate volume flow and peak rate of volume flow along with good accuracy of control.

NACA RM L53H13

THE AERODYNAMIC CHARACTERISTICS AT TRANSONIC SPEEDS OF AN ALL-MOVABLE, TAPERED, 45° SWEPTBACK, ASPECT-RATIO-4 TAIL DEFLECTED ABOUT A SKEWED HINGE AXIS AND EQUIPPED WITH AN INSET UNBALANCING TAB. James M. Watson. September 1953. 40p. diagrs. (NACA RM L53H13) (Declassified from Confidential, 10/12/54)

This paper contains the results of an investigation at transonic speeds of an all-movable, aspect-ratio-4, taper-ratio-0.6 tail swept back 45° at the quarter-chord line, and deflected about a skewed hinge axis located behind the centers of pressure. The tail was equipped with an inset tab. Lift, pitching-moment, and hinge-moment data are presented for various tail angles of attack and deflections and tab deflections through a Mach number range of 0.61 to 1.21 obtained by the transonic-bump technique.

CURRENT NACA REPORTS

NACA TM 1380

CONTRIBUTION TO THE THEORY OF TAIL-WHEEL SHIMMY. (Beitrag zur Theorie des Spornradflatterns). M. Melzer. December 1954. 37p. diagrs., 7 tabs. (NACA TM 1380. Trans. from Focke-Wulf Flugzeugbau G. m. b. H., Bremen, Technische Berichte, v. 7, no. 2, 1940)

A basic theoretical and experimental investigation is made of the shimmy behavior of a swiveling landing gear, the experimental tests being conducted with a small wheel mounted over a continuous belt. Effects of wheel loading, rolling velocity, rearward position of the wheel with respect to the swivel axis, tire elasticity, and torsional flexibility of the fuselage are investigated both experimentally and theoretically. A major theoretical conclusion is that the motion of a landing gear moving in a straight line without fuselage elasticity is stable for a sufficiently large rearward position of the wheel behind the swivel axis, and this conclusion is well verified quantitatively by the experimental data.

NACA TN 3240

THEORETICAL CALCULATIONS OF THE LATERAL STABILITY DERIVATIVES FOR TRIANGULAR VERTICAL TAILS WITH SUBSONIC LEADING EDGES TRAVELING AT SUPERSONIC SPEEDS. Percy J. Bobbitt. December 1954. 68p. diagrs., photos., 5 tabs. (NACA TN 3240)

Pressure-distribution expressions and stability derivatives have been derived for zero-end-plate triangular vertical tails performing yawing, rolling, and constant-lateral-acceleration motions by a method for solving supersonic-conical flow boundary-value problems. In addition, by using the yawing and constant-lateral-acceleration results, the damping of the vertical tail oscillating laterally in yaw has been approximated to the first order in frequency. End-plate effects have been discussed and suggestions made to aid in their evaluation. In this connection the complete-end-plate and no-end-plate stability derivatives for the sideslip motion obtained from other sources have been considered. The pressure-distribution expressions and stability derivatives presented are valid for a range of Mach numbers for which the leading edge is subsonic and the trailing edge supersonic.

NACA TN 3251

A THEORETICAL INVESTIGATION OF THE SHORT-PERIOD DYNAMIC LONGITUDINAL STABILITY OF AIRPLANE CONFIGURATIONS HAVING ELASTIC WINGS OF 0° TO 60° SWEEPBACK. Milton D. McLaughlin. December 1954. 39p. diagrs., 2 tabs. (NACA TN 3251)

An analytical investigation utilizing the semirigid approach was made to determine the effects of wing flexibility on the dynamic longitudinal stability of thin-wing airplane configurations. The configurations were assumed to vary in wing sweep angle from 0° to 60°, in center-of-gravity location from 25 percent mean aerodynamic chord to 45 percent mean aerodynamic chord, and in ratio of wing mass to airplane mass from 0.15 to 0.50. Solutions were obtained in the form of frequency and damping of the flexible wing mode and of the airplane short-period stability mode. Results are compared with those obtained by simplified methods.

NACA TN 3267

BOUNDARY-LAYER TRANSITION AT MACH 3.12 WITH AND WITHOUT SINGLE ROUGHNESS ELEMENTS. Paul F. Brinich. December 1954. 41p. diagrs. (NACA TN 3267)

Transition on a hollow cylinder alined with the air stream was studied in a Mach 3.12 wind tunnel at Reynolds numbers from 1×10^5 to 7×10^5 per inch. Transition was observed from surface-temperature distributions and schlieren photographs with and without single roughness elements. Without roughness, the transition Reynolds number varied as the square root of the stream Reynolds number per inch. The results obtained with roughness followed the trends of Dryden's low-speed correlation. The degree of roughness required was found to be three to seven times as great as for low-speed flows.

NACA TN 3280

ELECTRICAL ANALOGIES FOR STIFFENED SHELLS WITH FLEXIBLE RINGS. R. H. MacNeal, California Institute of Technology. December 1954. 35p. diagrs., 2 tabs. (NACA TN 3280)

First, an electrical analogy is developed for a circular shell with a straight axis and variable radius. This analogy is extended to noncircular cylinders. Then an electrical analogy is derived for

*AVAILABLE ON LOAN ONLY.
ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

rings with variable radii of curvature; a simplified circuit for circular rings is also presented. The simplifications that occur when the rings are assumed to be rigid are discussed. Finally, results are given for two sample problems solved on an analog computer. The second problem concerns a cantilever conical shell and illustrates the manner in which the shell and ring circuits are interconnected.

NACA TN 3288

ON THE ANALYSIS OF LINEAR AND NONLINEAR DYNAMICAL SYSTEMS FROM TRANSIENT-RESPONSE DATA. Marvin Shinbrot. December 1954. 51p. diagrs., 6 tabs. (NACA TN 3288)

A general theory of the so-called "equations-of-motion" methods for linear dynamical systems is developed first. It is then shown that when viewed from this general point of vantage, all of these linear methods can be extended in a perfectly natural way to apply to nonlinear systems. In addition, through use of this theory, a new method, possessing certain advantages over previous methods, is derived. Application of this method is demonstrated by several examples.

NACA TN 3301

COMPARISON OF FLUTTER CALCULATIONS USING VARIOUS AERODYNAMIC COEFFICIENTS WITH EXPERIMENTAL RESULTS FOR SOME RECTANGULAR CANTILEVER WINGS AT MACH NUMBER 1.3. Herbert C. Nelson and Ruby A. Rainey. November 1954. 22p. diagrs., 2 tabs. (NACA TN 3301)

A general Rayleigh analysis is used as a basis for developing four methods of flutter analysis that are applied to twelve rectangular low-aspect-ratio wings with aspect ratios ranging from 3.00 to 4.55. These wings were previously tested at a Mach number of 1.3 by progressively varying certain wing parameters until flutter occurred. The four methods of flutter analysis used are: section coefficients for harmonically pitching and translating rectangular wings in a Rayleigh type of analysis, two-dimensional coefficients in a Rayleigh type of analysis, total coefficients for harmonically pitching and translating rectangular wings in a representative-section analysis, and two-dimensional coefficients in a representative-section analysis. Each of the four methods involves two degrees of freedom, namely, first bending and first torsion of a cantilever wing. Comparison of the analytical and experimental results indicates that the use of aerodynamic coefficients derived on the basis of three-dimensional flow leads to a significant improvement in the correlation of theory and experiment.

NACA TN 3304

INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF A MODEL WING-PROPELLER COMBINATION AND OF THE WING AND PROPELLER SEPARATELY AT ANGLES OF ATTACK UP TO 90°. John W. Draper and Richard E. Kuhn. November 1954. 72p. diagrs., photos., tab. (NACA TN 3304)

Results are presented of a wind-tunnel investigation of the effects of slipstream for two large-diameter propellers on the aerodynamic characteristics of a wing model. The investigation covered angles of attack from -10° to 90° and thrust coefficients representing free-stream velocities from zero to the normal range of cruising flight. An appreciable increase in the angle of attack for maximum lift with increasing power is indicated. A modification of the method of Smelt and Davies for estimating the effects of slipstreams on the lift-curve slope is presented. Performance calculations for an assumed vertical take-off airplane are also included. Forces and moments on the wing-propeller combination and on the wing and propellers separately are included. A large nose-up pitching moment on the propeller itself was found at high angles of attack.

NACA TN 3306

AN INVESTIGATION OF A LIFTING 10-PERCENT-THICK SYMMETRICAL DOUBLE-WEDGE AIRFOIL AT MACH NUMBERS UP TO 1. Milton D. Humphreys. November 1954. 35p. diagrs., photos., tab. (NACA TN 3306)

Subsonic and transonic pressure-distribution and drag-coefficient measurements on a two-dimensional 10-percent-thick symmetrical double-wedge airfoil for a range of angles of attack are presented and compared with theory and existing experimental data.

NACA TN 3307

AN INVESTIGATION OF A WING-PROPELLER CONFIGURATION EMPLOYING LARGE-CHORD PLAIN FLAPS AND LARGE-DIAMETER PROPELLERS FOR LOW-SPEED FLIGHT AND VERTICAL TAKE-OFF. Richard E. Kuhn and John W. Draper. December 1954. 94p. diagrs., photos. (NACA TN 3307)

An investigation of the effectiveness of a wing equipped with large-chord plain flaps and auxiliary vanes in rotating the effective thrust vector from two large-diameter propellers to a near vertical attitude for vertical take-off and low-speed flight has been conducted in the Langley 300 mph 7- by 10-foot tunnel. The model consisted of a semispan wing equipped with a 60-percent-chord and a 30-percent-chord plain flap. Two large-diameter overlapping propellers, driven by electric motors, were used. The tests covered a range of angle of attack from 0° to 90° and a thrust-coefficient range representative of free-flight velocities from zero to the normal range of cruising velocities.

NACA TN 3309

MECHANICAL PROPERTIES AT ROOM TEMPERATURE OF FOUR CERMETS OF TUNGSTEN CARBIDE WITH COBALT BINDER. Aldie E. Johnson, Jr. December 1954. 16p. diagrs., photo., tab. (NACA TN 3309)

Room-temperature stress-strain curves are presented for compression, tension, and shear loadings on four compositions of tungsten carbide with cobalt binder. Values of modulus of elasticity, modulus of rigidity, Poisson's ratio in the elastic region, ultimate strength, density, and hardness for the four materials are tabulated.

NACA TN 3312

INITIAL EXPERIMENTS ON FLUTTER OF UNSWEPT CANTILEVER WINGS AT MACH NUMBER 1.3. W. J. Tuovila, John E. Baker and Arthur A. Regier. November 1954. 19p. diagrs., photos., 2 tabs. (NACA TN 3312. Formerly RM L8J11)

This paper contains experimental data for the bending torsion flutter of unswept cantilever wings at Mach number of 1.3. Comparison with the theory of flutter at supersonic speeds indicates that the theory is applicable in predicting cantilever-wing flutter. These preliminary experiments consider also various overall effects of center-of-gravity location, elastic-axis location, mass-density parameter, section shape, and some wing-tip moments of inertia.

NACA TN 3316

SOME MEASUREMENTS OF NOISE FROM THREE SOLID-FUEL ROCKET ENGINES. Leslie W. Lassiter and Robert H. Heitkotter. December 1954. 21p. diagrs. (NACA TN 3316)

Results of a systematic experimental investigation of the sound field of one type of rocket engine are given. These comprise frequency spectra and overall pressure data as obtained along a semicircle of 50-foot radius about the engine. The spectra are shown to be of random nature and the angular distribution is shown to have a maximum at an angle of about 45° off the jet axis downstream of the nozzle. Frequency spectra and overall pressure magnitudes are also given for a few isolated points in the sound fields of two other solid-fuel rockets.

NACA TN 3320

FLIGHT MEASUREMENTS OF DRAG AND BASE PRESSURE OF A FIN-STABILIZED PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT DIFFERENT REYNOLDS NUMBERS AND AT MACH NUMBERS FROM 0.9 TO 3.3. H. Herbert Jackson, Charles B. Rumsey and Leo T. Chauvin. November 1954. 20p. diagrs., photos. (NACA TN 3320. Formerly RM L50G24)

Free-flight tests at supersonic speeds have been made to determine the Reynolds number effects on total drag and base drag of a fin-stabilized parabolic-arc body of revolution having a body fineness ratio of 12.2 and designated the NACA RM-10 configuration. The Reynolds number range of 14×10^6 to 210×10^6 was obtained by testing full-scale and half-scale models through the Mach number range from 0.9 to 3.3.

NACA TN 3328

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF HEAT TRANSFER BY LAMINAR NATURAL CONVECTION BETWEEN PARALLEL PLATES. A. F. Lietzke. December 1954. 23p. diagrs. (NACA TN 3328)

For the experimental work, parallel walls (one heated uniformly and the other cooled uniformly) were simulated by an annulus with an inner-to-outer diameter ratio near 1. The theoretical results are presented in equations for the velocity and temperature profiles and the ratio of actual temperature drop across the fluid to temperature drop for pure conduction. No experimental measurements were made of the velocity and temperature profiles, but the experimental results are compared with theory on the basis of the ratio of the actual temperature drop to the temperature drop for pure conduction. Good agreement was obtained between theory and experiment for axial temperature gradients above 40° F/ft.

NACA TN 3333

CORROSION OF METALS OF CONSTRUCTION BY ALTERNATE EXPOSURE TO LIQUID AND GASEOUS FLUORINE. Richard M. Gundzik and Charles E. Feiler. December 1954. 10p. photos., 3 tabs. (NACA TN 3333)

The corrosion of 3S-0 and 52S-0 aluminum, AISI 347 and 321 stainless steels, "A" nickel, and low-leaded brass by alternate exposure to liquid and gaseous fluorine has been determined for periods of up to 3-1/2 months. Under the conditions of the experiments, the corrosion of these metals was found to be negligible.

NACA TN 3341

AN ANALYTICAL ESTIMATION OF THE EFFECT OF TRANSPIRATION COOLING ON THE HEAT-TRANSFER AND SKIN-FRICTION CHARACTERISTICS OF A COMPRESSIBLE TURBULENT BOUNDARY LAYER. Morris W. Rubesin. December 1954. 56p. diagrs. (NACA TN 3341)

An analysis based on mixing-length theory is presented which indicates that surface blowing associated with transpiration cooling systems produces large reductions in both the heat-transfer and skin-friction coefficients for a turbulent boundary layer on a flat plate. The numerical results are restricted to the case of air blowing into air. The effects of blowing are indicated to be similar for high-speed, compressible flow to those for low-speed, incompressible flow.

NACA TN 3344

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF AERODYNAMIC-HEATING AND ISOTHERMAL HEAT-TRANSFER PARAMETERS ON A HEMISPHERICAL NOSE WITH LAMINAR BOUNDARY LAYER AT SUPERSONIC MACH NUMBERS. Howard A. Stine and Kent Wanlass. December 1954. 48p. diagrs., photo., tab. (NACA TN 3344)

Measurements of the heat-transfer parameter, $Nu/\sqrt{Re}$, based on local flow conditions just outside the boundary layer and length of boundary-layer run were carried out on the heated, isothermal surface of a hemisphere-cylinder for a Mach number of 1.97 and Reynolds numbers based on body diameter from 0.60×10^6 to 2.28×10^6. An approximate method for calculating the distribution of heat-transfer parameter, applicable to any body of revolution, was developed which agrees well with the experimental results.

NACA TN 3348

A SYSTEM FOR MEASURING THE DYNAMIC LATERAL STABILITY DERIVATIVES IN HIGH-SPEED WIND TUNNELS. Henry C. Lessing, Thomas B. Fryer and Merrill H. Mead. December 1954. 42p. diagrs., photo. (NACA TN 3348)

A two-degree-of-freedom system in which rolling oscillations are forced is described. Details of the system, the theory, and the method of operation are discussed. Tests are described in which certain of the aerodynamic derivatives were simulated, and the results of these tests, as well as the results of a wind-tunnel investigation of a simple model, are presented.

THE APPLICATION OF CAMBER AND TWIST TO SWEPT WINGS IN INCOMPRESSIBLE FLOW. G. G. Brebner. 1954. 59p. diagrs., 2 tabs. (ARC CP 171)

This report provides a method of calculating the effect of a certain type of camber on the chordwise and spanwise loading of any wing in incompressible potential flow. A detailed description is given of the method of calculating the loading on a given cambered swept wing. The design of wings incorporating camber and twist to produce required chordwise and spanwise loadings is treated in detail. It is shown that at any spanwise position only one particular combination of camber and incidence will give a required chordwise loading.

A NOTE ON THE BOUNDARY LAYER AND STALLING CHARACTERISTICS OF AEROFOILS. D. D. Carrow. 1954. 20p. diagrs. (ARC CP 174)

A qualitative explanation is suggested for the changes which occur in the stalling characteristics of airfoils as the Reynolds number is increased. This explanation is based on the variation, with Reynolds number, in the state of the boundary layer along the upper surface at just below the stalling incidence. Examples are given of the effect of Reynolds number and of leading edge roughness on the stalling characteristics of several airfoils, the changes from one type of stall to another being explained, in each case, by an alteration in the type of transition region. Five major types of stall are explained according to the manner in which the flow separation at the stall develops.

FLIGHT TRIALS OF A ROCKET-PROPELLED TRANSONIC RESEARCH MODEL: THE R. A. E. - VICKERS ROCKET MODEL, PARTS I TO IV. Staff of the Supersonics Division, Flight Section. 1954. 63p. diagrs., photos., 2 tabs. (ARC R & M 2835; ARC 13,658. Formerly RAE Aero 2357)

The main body of the report contains a historical review of the project, brief descriptions of the test vehicles and experimental techniques, and the detailed analysis of the final successful flight trial. It is concluded that the method is an extremely difficult one and that the results it gives do not justify the effort it demands. Detailed descriptions of the test vehicle and its ancillary equipment are given in appendices; the work leading up to the final trial and the experimental methods and techniques are described. The model was air-launched at 36,000 feet above a ground radar station.

THE FREQUENCY RESPONSE OF THE ORDINARY ROTOR BLADE, THE HILLER SERVO-BLADE, AND THE YOUNG-BELL STABILISER. G. J. Sissingh. 1954. 19p. diagrs., 2 tabs. (ARC R & M 2860; ARC 13,592. Formerly RAE Aero 2367)

The report deals with the frequency response of pivoted gyratory systems, and in particular, with the response of the ordinary rotor blade, the Hiller servo-blade, and the Young-Bell stabilizer to sinusoidal disturbances caused by pitching oscillations with constant amplitude. Explicit formulas are given for each individual system and the effect of the frequency ratio on the control characteristics of the Bell stabilizer and the Hiller servo-blade is shown by vector loci.

WATER AND AIR PERFORMANCE OF SEAPLANE HULLS AS AFFECTED BY FAIRING AND FINENESS RATIO. A. G. Smith and J. E. Allen. 1954. 27p. diagrs., 5 tabs. (ARC R & M 2896; ARC 13,644. Formerly MAEE F/Res/219)

An analysis is made of data on the variation of hull air drag with length-beam ratio and degree of local fairing, and of the maximum beam loading permitted for reasonable hydrodynamic performance. The effect of length-beam ratio on hull structure weight is also discussed. Charts are given to help in the selection of the best hull form for any given design conditions. From these may be estimated dimensions, air drag, and the maximum beam loading to give a reasonable standard of water performance.

A NOTE ON THE DYNAMIC STABILITY OF AIRCRAFT AT HIGH-SUBSONIC SPEEDS WHEN CONSIDERING UNSTEADY FLOW. W. J. G. Pinsker. 1954. 28p. diagrs., 7 tabs. (ARC R & M 2904; ARC 13,567. Formerly RAE Aero 2378)

The effect of an increase in speed relative to the speed of sound on the unsteady flow around a harmonically oscillating airfoil, is to increase the lag of the aerodynamic forces and moments behind the deflection when the frequency is small. It is shown theoretically that this will result in a serious deterioration of the damping of both the lateral oscillation and the high frequency longitudinal oscillation with high Mach numbers. Use is made of derivatives calculated for flutter purposes to estimate the unsteady derivatives at aircraft oscillation frequencies. Illustrative examples are presented.

METHODS OF TESTING REINFORCED PLASTICS, PARTS I AND II. F. T. Bartwell. 1954. 34p. diagrs., photos., 13 tabs. (ARC R & M 2702; ARC 11,375. Formerly ARC 10,095; Strut 1088)

An experimental comparison has been made between five types of tensile tests including novel types designed to enable axial loading conditions to be approached more readily than is the case with established methods. Examination of the results of 240 tests indicates that significant differences can occur between the results of different tests and that there is also a significant variation between the properties of material cut from different parts of the same sheet. It is concluded that the results, obtained when testing paper-base material by novel methods, are sufficiently good to justify development of a simplified apparatus of similar type for general use.

Aeronautical Research Council (Gt. Brit.)
THE INFLUENCE OF THICKNESS/CHORD RATIO ON SUPERSONIC DERIVATIVES FOR OSCILLATING AEROFOILS. W. P. Jones. 1954. 17p. diagrs., 3 tabs. (ARC R&M 2679. Formerly ARC 10,871; 0.678; FM 1153)

By the use of Temple and Jahn's theory for the oscillating flat plate and Busemann's theory for airfoils in steady motion, derivatives are obtained for symmetrical circular-arc and double-wedge airfoils describing low frequency oscillations at supersonic speeds. It is known that theoretically the torsional aerodynamic damping for a flat plate oscillating about an axis forward of the two-thirds chord position is negative at low frequencies for a limited range of supersonic speeds. In this report, however, it is shown that the effect of increasing thickness/chord ratio is to decrease the range of speeds for which the aerodynamic damping is negative, and for which the degree of freedom flutter is possible. The present theory also allows for the forward movement of the center of pressure from the half-chord position as the airfoil thickness is increased, and leads to better estimates of the stiffness derivatives for an actual airfoil. In practice the center of pressure is not at half-chord as predicted by linear theory.

THEORETICAL CALCULATIONS OF THE DISTRIBUTION OF AERODYNAMIC LOADING ON A DELTA WING. H. C. Garner. 1954. 33p. diagrs., 9 tabs. (ARC R & M 2819. Formerly ARC 12,222; Perf. 538; S & C 2295)

The distribution of velocity potential has been calculated for a thin, flat, delta wing at small incidence. The method introduces novel functions with 10 arbitrary constants to express the doublet distribution over the wing and a special numerical integration to evaluate the downwash at 10 chosen points on the surface. Three different forms of the doublet distribution are employed and lead to three independent solutions of the resulting simultaneous equations. One object of the paper is to form the first step towards a fundamental comparison with measured pressure distributions.

THE EFFECT OF HARD ANODIC COATINGS ON THE FATIGUE STRENGTH OF D. T. D. 364B ALUMINIUM ALLOY. E. G. Savage, E. G. F. Sampson and J. K. Curran. June 1954. 10p. diagrs., 4 tabs. (RAE Tech. Note Met. 200)

Wöhler-type fatigue tests were made on D. T. D. 364B aluminum alloy test pieces which had been anodised under conditions previously described in order to produce hard coatings of about 0.001- or 0.002-inch thickness. Control tests were made on unanodised test pieces. Film thickness, surface roughness, and change of dimensions were also determined. Hard anodising reduced the fatigue strength of the test pieces by about one half, the reductions being of the same order for each thickness of coating. The anodic treatment increased the average roughness of the surfaces from about 4 to 50 microinches and increased the diameter of the test pieces by about 60 percent of the total film thickness. A possible method of reducing the ill-effects of hard anodising is described and further work is proposed.

Royal Aircraft Establishment (Gt. Brit.)
SOME PROBLEMS IN AERODYNAMICS AND THEIR SOLUTION BY ELECTRICAL ANALOGY. D. Küchemann and S. C. Redshaw. August 1954. 16p. (RAE Tech. Note Aero 2323)

Some purely aerodynamical phenomena, which might profitably be investigated by means of electrical analogue computers, are described. No attempt has been made to furnish a complete catalogue of problems but rather to present current issues, the solution of which would aid the development of practical aerodynamics. Consideration has only been given to those questions which can be solved more suitably by an analogue computor rather than by a digital machine, although the feasibility of partially solving certain of them by the use of an analogue computer, and completing the work with a digital machine, is mentioned. In scope, the survey includes two- and three-dimensional airfoils as well as interference and a number of special problems. The relative merits of the various forms of analogue computors are not extensively discussed.

THE EFFECT OF HEATING STEELS TO MODERATELY ELEVATED TEMPERATURES. G. Meikle and M. S. Binning. June 1954. 18p. diagrs., 5 tabs. (RAE Tech. Note Met. 199)

A review has been made of available information on the strength of structural steels up to temperatures of the order of 350° C. Experiments have been made to determine the strength of aircraft steels from 100° C to 350° C and the effect of heating at selected temperatures for different periods was determined. The percentage loss in strength and Young's Modulus was found to be fairly constant for all the ferritic steels at any particular temperature. No evidence was obtained that the length of time of heating, up to 1000 hours, had any additional deleterious effect.

Royal Aircraft Establishment (Gt. Brit.)
A CURVE FOLLOWER FOR DISCONTINUOUS CURVES ON 35mm. FILM. O. H. Lange and G. J. Herring. August 1954. 16p. diagrs. (RAE Tech. Note GW 334)

A photo-electric system is described by means of which the voltage analogue of the ordinates of the curve of a single-valued function can be obtained to

an accuracy of approximately 2 percent of the maximum ordinate. No restriction is placed on the maximum slope of the curve, which is fed into the machine as a trace on a film which may be of any length. Circuits for the electronic components are given and some applications are indicated.

N-34401*

Royal Aircraft Establishment (Gt. Brit.) CONSIDERATION OF SOME NEW LOW-DENSITY MATERIALS. G. A. Horridge. June 1954. 18p. diagrs., photos. (RAE Tech. Note Chem. 1232)

It would be an advantage from the point of view of structural efficiency to have a material that can be moulded to form primary structures with a specific gravity considerably less than existing reinforced plastics. There is available at present a range of low-density core materials which are used for sandwich construction but a consideration of foamed resins has not yet shown any promise that they can be used as a basis for a low-density primary structural material. . This is because absolute strengths are low and orientated reinforcement in the foam has not improved the mechanical properties for competition with existing primary materials. An alternative method to reduce the specific gravity of reinforced plastics lies in the use of glass tubes instead of fibers as reinforcement. Results of tests on such materials have so far been promising and theoretical considerations show both the limits of the effectiveness of such reinforcement and the direction in which to aim to produce a material of given properties.

N-34402*

Marine Aircraft Experimental Establishment (Gt. Brit.) METHOD FOR REDUCING SEAPLANE TAKE-OFF DISTANCES TO STANDARD CONDITIONS. J. A. Hamilton. April 1954. 44p. diagrs., photos., 10 tabs. (MAEE F/Res/245)

In this report are developed methods for the reduction of seaplane take-off distances to standard conditions of weight, wind, and ambient temperature. The expressions derived are applicable to the waterborne run and to the airborne run up to the 50-foot height point. The methods may be applied to take-off with simulated engine failure. The theoretical results are in good agreement with measurements made on reciprocating engined seaplanes of 9000 lb and 78, 000 lb weight for winds up to 20 knots, weight changes of 20 percent, and a temperature range of 2° to 32° C. However, the general application of the corrections should be limited to temperature changes of less than 10° C, weight changes of less than 10 percent, and wind changes of less than 10 knots. These ranges should be adequate for the majority of flight trials conducted in one location.

N-34406*

Aeronautical Research Council (Gt. Brit.) THE GROWTH OF A VORTEX IN TURBULENT FLOW. H. B. Squire. March 18, 1954. 6p. diagrs. (ARC 16,666; FM 2053)

The growth of a line vortex with time and the spread of a trailing vortex behind a wing due to turbulence are considered. It is shown that the eddy viscosity for this type of motion may be taken to be proportional to the circulation round the vortex and the solution is then similar to the solution for the growth of a vortex in laminar flow. The method is applied to calculate the distance behind a wing for which the trailing vortices will touch one another.

Advisory Group for Aeronautical Research and Development. DESIGN AND OPERATION OF INTERMITTENT SUPERSONIC WIND TUNNELS. A. Ferri and S. M. Bogdonoff. May 1954. 108p. diagrs., photo. (AGARDograph 1)

A study has been made of the operating characteristics of intermittent wind tunnels, particularly of the blowdown type. For the same test Mach and Reynolds numbers, the blowdown tunnel is considerably cheaper to build and to operate than the comparable continuous tunnel. For tests of many different setups, flexibility may be more important than long running time. Typical construction, test setup, instrumentation, and extensions to the transonic and hypersonic region have been discussed. Some examples of operating intermittent tunnels are also given.

UNPUBLISHED PAPERS

N-33708*

FLOW NEAR THE FORWARD TIP OF A HIGHLY SWEPT WING AT MEDIUM ANGLES OF ATTACK - PART I. (Écoulement au Voisinage de la Pointe Avant d'une Aile a Forte Flèche aux Incidences Moyennes). Robert Legendre. (Presented at Eighth International Congress of Theoretical and Applied Mechanics, Istanbul, August 1952). November 1954. 18p. diagrs. (Trans. from Recherche Aéronautique, no. 30, 1952, p. 3-8)

An interpretation is made of the turbulent flow which originates at the forward tip of a highly swept wing as soon as the angle of attack is about 10°. The case considered is a plane, triangular, infinitely slender wing. The method employed is Jones' method of transverse sections. When the angle of attack of a highly swept wing is sufficient, well-defined vortices appear on the upper side of the wing. They correspond approximately to the field which would be induced by two rectilinear free vortices originating at the wing tip.

N-33709*

FLOW NEAR THE FORWARD TIP OF A HIGHLY SWEPT WING AT MEDIUM ANGLES OF ATTACK - PART II. (Écoulement au Voisinage de la Pointe Avant d'une Aile a Forte Flèche aux Incidences Moyennes). Robert Legendre. (Presented at Eighth International Congress of Theoretical and Applied Mechanics, Istanbul, August 1952). November 1954. 12p. diagrs. (Trans. from Recherche Aéronautique, no. 31, Jan.-Feb., 1953, p. 3-6)

The flow which originates in the neighborhood of the forward tip of a highly swept wing at medium angles of attack was previously schematized by the field of two isolated vortices. This study replaces the schematic representation by the field of the vortex sheets attached to the two leading edges of the wing. It is limited to the setting-up and the discussion of the integral-differential equation of the problem.

DECLASSIFIED NACA REPORTS

We have

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM CONFIDENTIAL, 11/30/54:

NACA RM A50G06

LOW-SPEED INVESTIGATION OF A 0.16-SCALE MODEL OF THE X-3 AIRPLANE - LONGITUDINAL CHARACTERISTICS. Noel K. Delany and Nora-Lee F. Hayter. September 8, 1950. 80p. diagrs., photos., 2 tabs. (NACA RM A50G06) (Declassified from Confidential, 10/29/54)

The low-speed, static, longitudinal characteristics of a model of the X-3 airplane have been determined with the wing flaps neutral and deflected. An investigation was also made of the effects of jettisonable-nose fins, landing gear and doors, scoops, and pilot's canopy on the longitudinal characteristics of the model. The X-3 airplane utilizes a wing of aspect ratio 3.01, a 4.5-percent-thick hexagonal section, and a taper ratio of 0.4. The wing was equipped with plain leading-edge flaps and split trailing-edge flaps.

NACA RM A50H02

EFFECT OF DIHEDRAL CHANGE ON THE THEORETICAL DYNAMIC LATERAL RESPONSE CHARACTERISTICS OF A LOW-ASPECT-RATIO STRAIGHT-WING SUPERSONIC AIRPLANE. Donovan R. Heinle. December 7, 1950. 35p. diagrs., 2 tabs. (NACA RM A50H02) (Declassified from Confidential, 10/29/54)

Theoretical calculations were made of the lateral-stability characteristics of a supersonic straight-wing low-aspect-ratio airplane. A Reeves Electronic Analog Computer was used to plot time histories of the lateral response to various distrubances and to obtain values of period, damping, and the roll excitation parameter. The effect of a change to negative geometric dihedral and changes in the yawing moment due to roll derivative $\left(C_{n_p}\right)$ were investigated.

NACA RM A51A16

LOW-SPEED INVESTIGATION OF A 0.16-SCALE MODEL OF THE X-3 AIRPLANE - LATERAL AND DIRECTIONAL CHARACTERISTICS. Noel K. Delany and Nora-Lee F. Hayter. March 16, 1951. 56p. diagrs., photos., tab. (RM A51A16) (Declassified from Confidential, 10/29/54)

A wind-tunnel investigation has been made of the low-speed, static, lateral, and directional characteristics of a model of an early design of the X-3 airplane with the wing flaps neutral and deflected. Measurements were also made of the fluctuations in rolling moment with time. The model utilized a wing having an aspect ratio of 3.01, a 4.5-percent-thick hexagonal section, and a taper ratio of 0.4. The wing was equipped with plain leading-edge flaps and split trailing edge flaps.

NACA RM A51H23

AERODYNAMIC CHARACTERISTICS OF A LEADING-EDGE SLAT ON A 35° SWEPT-BACK WING FOR MACH NUMBERS FROM 0.30 TO 0.88. John A. Kelly and Nora-Lee F. Hayter. December 1951. 49p. diagrs., tab. (NACA RM A51H23) (Declassified from Confidential, 11-30-54)

North American Aviation, Inc., has furnished the NACA with data obtained from tests which were made at Mach numbers from 0.300 to 0.883 to determine the lift, drag, and pitching-moment characteristics of a semispan model of a 35° sweptback wing with a leading-edge slat. The wing was tested in the presence of a fuselage. Measurements were made of the pressures acting on the slat in the retracted and full-open positions. These pressure data were analyzed to ascertain the slat opening-force characteristics for two possible circular-arc slat tracks which could be used for automatic operation of the slat.

NACA RM A51J25a

A SUMMARY OF AVAILABLE KNOWLEDGE CONCERNING SKIN FRICTION AND HEAT TRANSFER AND ITS APPLICATION TO THE DESIGN OF HIGH-SPEED MISSILES. Morris W. Rubesin, Charles B. Rumsey and Steven A. Varga. November 1951. 17p. diagrs. (NACA RM A51J25a) (Declassified from Confidential, 10/29/54)

A review is made of the existing information concerning boundary-layer characteristics: the temperature recovery, the skin-friction coefficients, the heat-transfer coefficients of both the laminar and turbulent boundary layers, and the position of the transition from laminar to turbulent flow. Comparison is made between existing flight data and results computed by the boundary-layer momentum-integral method in a preliminary attempt to establish some rational way of approaching the design of a missile whose Mach number range and body geometry are markedly different from those of existing data.

NACA RM A52I19a

INVESTIGATION OF AN NACA 4-(5)(05)-041 FOUR-BLADE PROPELLER WITH SEVERAL SPINNERS AT MACH NUMBERS UP TO 0.90. Robert M. Reynolds, Donald A. Buell and John H. Walker. December 1952. 86p. diagrs., photos., 6 tabs. (NACA RM A52I19a) (Declassified from Confidential, 10/29/54)

This paper presents the propeller characteristics of the NACA 4-(5)(05)-041 four-blade, single-rotation propeller in combination with two NACA 1-series spinners and two extended cylindrical spinners for a wide range of blade angles at Mach numbers up to 0.90. Included are data for the propeller operating at negative thrust at low forward speeds and operating at near-static conditions. A description of the 1000-horsepower propeller dynamometer is included.

NACA RM A52J17

CORRELATION OF BUFFET BOUNDARIES PREDICTED FROM WIND-TUNNEL TESTS WITH THOSE MEASURED DURING FLIGHT TESTS ON THE F8F-1 AND X-1 AIRPLANES - TRANSONIC-BUMP METHOD. Andrew Martin and James F. Reed. December 1952. 22p. diagrs., photos., tab. (NACA RM A52J17) (Declassified from Confidential, 10/29/54)

Wing-fuselage-combination models of the F8F-1 and X-1 airplanes have been tested in the Ames 16-foot high-speed wind tunnel utilizing the transonic-bump technique. Presented for these models are the lift and pitching-moment coefficients, and fluctuating wing-bending-moment and wake-pressure data. Comparisons are presented of buffet boundaries estimated from these data with flight-determined buffet boundaries.

NACA RM E52A14

DYNAMIC RESPONSE OF TURBINE-BLADE TEMPERATURE TO EXHAUST-GAS TEMPERATURE FOR GAS-TURBINE ENGINES. Richard Hood and William E. Phillips, Jr. February 1952. 41p. photos., diagrs. (NACA RM E52A14) (Declassified from Confidential, 11-30-54)

The frequency response of blade temperature to exhaust gas temperature is presented for two locations in the blade and at several operating conditions. The frequency response was determined by Fourier analysis of transient data. Two analytical methods are presented, and the results are compared with experimental data. The dynamic response of turbine-blade temperature to exhaust-gas temperature exhibited the form of an approximate first-order lag. The results are used to predict blade temperature for a typical controlled and uncontrolled gas-turbine engine.

NACA RM L8L31

THEORETICAL INVESTIGATION OF THE DYNAMIC LATERAL STABILITY CHARACTERISTICS OF DOUGLAS DESIGN NO. 39C, AN EARLY VERSION OF THE X-3 RESEARCH AIRPLANE. Charles V. Bennett. January 18, 1949. 39p. diagrs., 2 tabs. (NACA RM L8L31) (Declassified from Confidential, 10/29/54)

Contains results of calculations made to determine the neutral oscillatory stability boundaries, period and time to damp of the oscillatory mode, and motions following distrubances. The calculations were made for Mach numbers of 0.75 and 2.3 at an altitude of 35,000 feet and for the landing condition at sea level.

NACA RM L9K08

STABILITY AND CONTROL CHARACTERISTICS AT LOW SPEED OF A 1/4-SCALE BELL X-5 AIRPLANE MODEL. LONGITUDINAL STABILITY AND CONTROL. William B. Kemp, Jr. Robert E. Becht and Albert G. Few, Jr. March 14, 1950. 51p. diagrs., photos. (NACA RM L9K08) (Declassified from Confidential, 10/29/54)

An investigation was conducted to determine the longitudinal stability and control characteristics at low speed of a 1/4-scale model of a preliminary X-5 airplane design. Tests were made through a range of wing sweep angles from 20° to 60° and several flap and slat configurations were investigated.

NACA RM L9L06

SPIN-TUNNEL INVESTIGATION OF A MODEL OF A 60° DELTA-WING AIRPLANE TO DETERMINE THE SPIN, RECOVERY, AND LONGITUDINAL TRIM CHARACTERISTICS THROUGHOUT AN EXTENSIVE RANGE OF MASS LOADINGS. Walter J. Klinar and Ira P. Jones, Jr. February 15, 1950. 56p. diagrs., photos., 6 charts, 4 tabs. (NACA RM L9L06) (Declassified from Confidential, 10/29/54)

An investigation has been conducted in the Langley 20-foot free-spinning tunnel to determine the spin and recovery characteristics of a 60° delta-wing model for a wide range of mass loadings. Variations were made in the relative density, center of gravity, and inertia yawing-moment parameter. In addition to the normal single-tail configuration, dual-vertical-tail configurations were also investigated. Glide tests were performed on the model and force tests were conducted from 0° to 90° angle of attack both on the model used for the dynamic tests and on a somewhat larger model to determine if any unusual trimming tendencies above the stall existed.

NACA RM L50B28

THEORETICAL INVESTIGATION OF THE DYNAMIC LATERAL STABILITY CHARACTERISTICS OF THE DOUGLAS X-3 RESEARCH AIRPLANE, STUDY 41-B. Charles V. Bennett. April 27, 1950. 31p. diagrs., 3 tabs. (NACA RM L50B28) (Declassified from Confidential, 10/29/54)

Contains results of calculations made to determine the period and damping of the lateral oscillation. The calculations were made for a Mach number of 0.75 at sea level and 35,000 feet and for Mach numbers of 1.2 and 2.0 at 35,000 and 50,000 feet. The effects of adding a rate gyro and the effects of certain geometric modifications were studied.

NACA RM L50C17a

STABILITY AND CONTROL CHARACTERISTICS AT LOW SPEED OF A 1/4-SCALE BELL X-5 AIRPLANE MODEL. LATERAL AND DIRECTIONAL STABILITY AND CONTROL. William B. Kemp, Jr. and Robert E. Becht. June 20, 1950. 97p. diagrs., photos. (NACA RM L50C17a) (Declassified from Confidential, 10/29/54)

An investigation was conducted to determine the lateral and directional stability and control characteristics at low speed of a 1/4-scale model of a preliminary Bell X-4 airplane design. Tests were made through a range of sweep angles from 20° to 60°, and several flap and slat configurations were investigated.

NACA RM L50E02a

LONGITUDINAL CHARACTERISTICS AT MACH NUMBER OF 1.24 OF 1/30-SCALE SEMISPAN MODEL OF BELL X-5 VARIABLE-SWEEP AIRPLANE WITH WING SWEPT BACK 60° FROM TESTS BY NACA WING-FLOW METHOD. Norman S. Silsby, Garland J. Morris and Robert M. Kennedy. October 12, 1950. 17p. diagrs., photos., tab. (NACA RM L50E02a) (Declassified from Confidential, 10/29/54)

Tests were made by the NACA wing-flow method to determine the longitudinal characteristics of a 1/30-scale semispan model of the Bell X-5 variable-sweep airplane with the wing in the 60° sweptback position and with tail incidences of -2° and -6°. Lift, drag, and pitching-moment results for various angles of attack are presented for a Mach number of 1.24. The Reynolds number was about 1×10^{6}.

NACA RM L50F23

STABILITY CHARACTERISTICS AT LOW SPEED OF A 1/4-SCALE BELL X-5 AIRPLANE MODEL WITH VARIOUS MODIFICATIONS TO THE BASIC MODEL CONFIGURATIONS. Robert E. Becht and Albert G. Few, Jr. August 16, 1950. 47p. diagrs., photo. (NACA RM L50F23) (Declassified from Confidential, 10/29/54)

An investigation was conducted to determine the low-speed longitudinal and lateral stability characteristics of a 1/4-scale model of a preliminary Bell X-5 airplane design incorporating dive brakes and several wing and fuselage modifications. Tests were made at 20° and 60° wing-sweep angles.

NACA RM L50I28

THE EFFECT OF SWEEPBACK ON THE LONGITUDINAL CHARACTERISTICS AT A MACH NUMBER OF 1.24 OF A 1/30-SCALE SEMISPAN MODEL OF THE BELL X-5 AIRPLANE FROM TESTS BY THE NACA WING-FLOW METHOD. Garland J. Morris, Robert M. Kennedy and Norman S. Silsby. November 27, 1950. 22p. diagrs., photos., tab. (NACA RM L50I28) (Declassified from Confidential, 10/29/54)

Tests were made by the NACA wing-flow method to determine the effect of sweepback angle on the longitudinal characteristics of a 1/30-scale semispan model of the Bell X-5 variable-sweep airplane with wings in the 40° and 50° positions. A test was also made with the fuselage alone. Lift, drag, and pitching-moment results for various angles of attack are presented for a Mach number of 1.24. The results are compared with the results of a previous test with the wing in the 60° position. The Reynolds number was about 1×10^6.

NACA RM L50J27

STABILITY AND CONTROL CHARACTERISTICS OF A 1/4-SCALE BELL X-5 AIRPLANE MODEL IN THE LANDING CONFIGURATION. Robert E. Becht. 38p. diagrs., photos. (NACA RM L50J27) (Declassified from Confidential, 10/29/54)

An investigation was conducted to determine the stability and control characteristics of a 1/4-scale model of a preliminary Bell X-5 airplane design in the landing configuration with and without dive brakes. Tests were made at wing sweep angles of 20° and 60°.

NACA RM L50K15

LONGITUDINAL-CONTROL EFFECTIVENESS AND DOWNWASH CHARACTERISTICS AT A MACH NUMBER OF 1.24 OF A 1/30-SCALE SEMISPAN MODEL OF THE BELL X-5 AIRPLANE AS DETERMINED BY THE NACA WING-FLOW METHOD. Richard H. Sawyer, Robert M. Kennedy and Garland J. Morris. January 8, 1951. 37p. diagrs., photos., tab. (NACA RM L50K15) (Declassified from Confidential, 10/29/54)

An investigation was made at a Mach number of 1.24 by the NACA wing-flow method to determine the longitudinal control effectiveness and downwash characteristics of a 1/30-scale semispan model of the variable sweep Bell X-5 airplane with the wing of the model swept back 60°, 50°, and 40°. Lift, drag, and pitching moments were obtained for various angles of attack for several horizontal tail settings and with tail off for each angle of sweep of the wing. The Reynolds number was about 1×10^6.

NACA RM L50L11a

EFFECTS OF A FUSELAGE FLAP DIVE BRAKE ON THE AERODYNAMIC CHARACTERISTICS OF 1/30-SCALE SEMISPAN MODEL OF THE BELL X-5 VARIABLE-SWEEP AIRPLANE AT A MACH NUMBER 1.24 AS DETERMINED BY THE NACA WING-FLOW METHOD. Robert M. Kennedy. February 8, 1951. 15p. diagrs., photos., tab. (NACA RM L50L11a) (Declassified from Confidential, 10/29/54)

An investigation was made by the NACA wing-flow method to determine the effect of a fuselage flap dive brake on the longitudinal characteristics of a 1/30-scale semispan model of the Bell X-5 variable-sweep airplane with the wing in the 60° sweptback position. Lift, drag, and pitching-moment results for various angles of attack are presented for a Mach number of 1.24. The results are compared with the results of a previous test without the dive brake. The Reynolds number of the tests was about 1×10^6.

NACA RM L50L19

STATIC LONGITUDINAL STABILITY AND DYNAMIC CHARACTERISTICS AT HIGH ANGLES OF ATTACK AND AT LOW REYNOLDS NUMBERS OF A MODEL OF THE X-3 SUPERSONIC RESEARCH AIRPLANE. Sanger M. Burk, Jr. and Burton E. Hultz. February 6, 1951. 76p. diagrs., photos., 4 tabs. (NACA RM L50L19) (Declassified from Confidential, 10/29/54)

An investigation was conducted in the Langley 20-foot free-spinning tunnel on a dynamic model and a static model representative of a supersonic airplane having a long nose and small wing to determine the motions and trim conditions possible

at high angles of attack. Tests were also conducted in the Langley 300 mph 7- by 10-foot tunnel on the static model to determine the effect of higher Reynolds numbers. The results of the investigation, in general, indicate that scale effect may appreciably influence free dynamic results obtained at low Reynolds numbers and high angles of attack on a design having a very long nose and a very small wing.

NACA RM L51H20a

SOME FLYING-QUALITIES STUDIES OF A TANDEM HELICOPTER. Kenneth B. Amer. October 1951. 29p. diagrs., photos. (NACA RM L51H20a) (Declassified from Confidential, 11-30-54)

Initial results of an investigation of the flying qualities of a representative tandem helicopter are presented. A comparison is made with previously published flying-qualities requirements based on studies of several single-rotor helicopters. A method is presented which gives promise of improving the longitudinal flying qualities of tandem helicopters with little weight penalty.

NACA RM L51I25

PRESSURE DISTRIBUTION AT LOW SPEED ON A 1/4-SCALE BELL X-5 AIRPLANE MODEL. William B. Kemp, Jr. and Albert G. Few, Jr. December 1951. 86p. diagrs., photos. (NACA RM L51I25) (Declassified from Confidential, 10/29/54)

An investigation was conducted at 20° and 60° sweep to determine the low-speed pressure distribution on the wing, wing slat, wing leading-edge fillet, and fuselage of a 1/4-scale model of a preliminary Bell X-5 airplane design. Included in the tests were investigations of nose-inlet velocity ratios with the jet exit duct fully open and partially closed.

NACA RM L51J18

WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF VARIOUS ASYMMETRIC CANOPY MODIFICATIONS ON THE BEHAVIOR OF DESCENDING PARACHUTES. Stanley H. Scher. February 1952. 20p. diagrs., photos., tab. (NACA RM L51J18) (Declassified from Confidential, 11/1/54)

Presented herein are the results of free-spinning tunnel tests made to determine the behavior in descent of eighteen 14-inch-diameter hemispherical and quasi-conical parachutes, having some various types of asymmetric canopy modifications and each having a cylindrical weight suspended below the parachute. The asymmetric modifications were made in an attempt to provide an appreciable lateral flight component of the parachute and cylinder.

NACA RM L51K22

INVESTIGATION OF THE LOW-SPEED AERODYNAMIC CHARACTERISTICS OF A VARIABLE-SWEEP AIRPLANE MODEL WITH A TWISTED AND CAMBERED WING. William B. Kemp, Jr., Robert E. Becht and Albert G. Few, Jr. February 1952. 62p. diagrs., photos. (NACA RM L51K22) (Declassified from Confidential, 10/29/54)

An investigation was conducted to determine the aerodynamic characteristics at low speed of a variable sweep airplane model with a twisted and cambered wing designed to have a uniform load distribution at a Mach number of 1.10 and a lift coefficient of 0.25 and 50° sweep. Comparison is made with data obtained on the same model with an untwisted, uncambered wing of the same geometric plan form. Also included in the investigation is the effect of partial-span split flaps.

NACA RM L51K27

INVESTIGATION OF THE DISTRIBUTION OF LIFT, DRAG, AND PITCHING MOMENT BETWEEN THE WING AND FUSELAGE OF A 1/30-SCALE SEMI-SPAN MODEL OF THE BELL X-5 AIRPLANE AT A MACH NUMBER OF 1.24 BY THE NACA WING-FLOW METHOD. Norman S. Silsby and Garland J. Morris. January 1952. 32p. diagrs., photos., tab. (NACA RM L51K27) (Declassified from Confidential, 10/29/54)

An investigation was made at a Mach number of 1.24 by the NACA wing-flow method to determine the distribution of lift, drag, and pitching moment between the wing and fuselage, the root bending moments of the wings, and the effect of wing flexibility (at 60° sweep) on the longitudinal stability characteristics of a 1/30-scale semispan model of the variable-sweep Bell X-5 airplane. Lift, drag, pitching moments, and wing root bending moments were obtained for various angles of attack. The Reynolds number was about 1.0×10^{6}.

NACA RM L52G21

THE VERTICAL-TAIL LOADS MEASURED DURING A FLIGHT INVESTIGATION ON A JET-POWERED BOMBER AIRPLANE. T. V. Cooney. May 1953. 32p. diagrs., photo. (NACA RM L52G21) (Declassified from Confidential, 11-30-54)

The vertical-tail loads measured in rudder kicks and gradual sideslips during a flight investigation of a jet bomber are presented, and the results are given of an analysis of the measured data to determine the vertical-tail lift-coefficient parameters $C_{L_{\alpha}}$ and $C_{L_{\delta}}$. The flight tests were performed at two altitudes, 20,000 feet and 30,000 feet, and covered the Mach number range from 0.30 to 0.76.

NACA RM L52I19a

THE EFFECTS OF A SMALL JET OF AIR EXHAUSTING FROM THE NOSE OF A BODY OF REVOLUTION IN SUPERSONIC FLOW. Eugene S. Love. November 1952. 45p. diagrs., photos. (NACA RM L52I19a) (Declassified from Confidential, 10/29/54)

Results are presented which show the effects at a Mach number of 1.62 of a small jet of air exhausting from the nose of an elliptical body of revolution upon boundary-layer transition and the viscous, pressure, and total drag of the forebody. Tests were conducted at Reynolds numbers of 2.13×10^6 and 7.66×10^6. The maximum range of thrust coefficients for the small jet was from 0 to about -0.085.

NACA RM L52I22

AN ANALYSIS OF ESTIMATED AND EXPERIMENTAL TRANSONIC DOWNWASH CHARACTERISTICS AS AFFECTED BY PLAN FORM AND THICKNESS FOR WING AND WING-FUSELAGE CONFIGURATIONS. Joseph Weil, George S. Campbell and Margaret S. Diederich. November 1952. 92p. diagrs., 2 tabs. (NACA RM L52I22) (Declassified from Confidential, 10/29/54)

This paper presents a summary of the effects of changes in wing plan form and thickness ratio on the downwash characteristics of wing and wing-fuselage configurations in the Mach number range between 0.6 and 1.1. Data obtained by the transonic-bump technique at two tail heights have been compared with theoretical estimations made in the subsonic and supersonic Mach number range.

NACA RM L52J09

INVESTIGATION AT TRANSONIC SPEEDS OF THE EFFECT OF A POSITIVE-LIFT BALANCING TAB ON THE HINGE-MOMENT AND LIFT CHARACTERISTICS OF A FULL-SPAN FLAP ON A TAPERED 45° SWEPTBACK WING OF ASPECT RATIO 3. Vernard E. Lockwood and Joseph E. Fikes. November 1952. 22p. diagrs., photo. (NACA RM L52J09) (Declassified from Confidential, 10/29/54)

Lift and hinge moments of a wing with a flap and balancing tab were obtained at transonic speeds by testing in the high-velocity field over a reflection plane on the side wall of the Langley high-speed 7- by 10-foot tunnel. The wing has a quarter-chord-line sweepback of 45.58° and aspect ratio of 3, and a taper ratio of 0.5 and was approximately 7.6 percent thick. The control consisted of 25.4-percent-chord full-span flap linked to an auxiliary lifting surface. The investigation was made over a limited tab-deflection and angle-of-attack range from M = 0.70 to 1.10 at a flap deflection of 3.9°.

NACA RM L52J10

EFFECTS OF SWEEPBACK AND TAPER ON THE FORCE AND CAVITATION CHARACTERISTICS OF ASPECT-RATIO-4 HYDROFOILS. Douglas A. King and Norman S. Land. December 1952. 61p. diagrs., photos., tab. (NACA RM L52J10) (Declassified from Confidential, 10/29/54)

An investigation was made to determine the effect of sweep and taper ratio on the cavitation and hydrodynamic characteristics of semispan hydrofoils of aspect ratio 4 and NACA 65A006 airfoil section. Sweep increased cavitation speed slightly, and taper had negligible effect. The large hydrodynamic twisting of the 60° swept hydrofoil obscured the effects of sweep. Complete cavitation limited the lift attainable to about 2000 lb/sq ft, 1210 lb/sq ft for the hydrofoil with 60° sweep. Chordwise progression of cavitation on unswept hydrofoil moved the center of pressure rearward.

NACA RM L52J13

A WIND-TUNNEL INVESTIGATION AT LOW SPEEDS OF THE AERODYNAMIC CHARACTERISTICS OF VARIOUS SPOILER CONFIGURATIONS ON A THIN 60° DELTA WING. Harleth G. Wiley and Martin Solomon. November 1952. 20p. diagrs. (NACA RM L52J13) (Declassified from Confidential, 10/29/54)

Results are presented of a preliminary wind-tunnel investigation at low speeds and angles of attack up to 36° to determine the rolling- and yawing-moment characteristics of various locations and configurations of spoilers on a thin 60° delta wing of constant thickness. Presented also are the effects of wing slots and spoiler perforations.

NACA RM L52J24

CHARACTERISTICS OF FLAP-TYPE SPOILER AILERONS AT VARIOUS LOCATIONS ON A 60° DELTA WING WITH A DOUBLE SLOTTED FLAP. Delwin R. Croom. December 1952. 31p. diagrs., 3 tabs. (NACA RM L52J24) (Declassified from Confidential, 10/29/54)

This paper contains results and discussion of a wind-tunnel investigation at low speeds of spoiler-type controls located at various chordwise and spanwise positions on a thin delta wing equipped with a double-slotted flap. Results indicated a spoiler located on the flap gave rolling-moment coefficients that varied fairly linearly with spoiler projections and were about the same magnitude for the flap-retracted or the flap-deflected condition.

National Advisory Committee for Aeronautics.
MEASUREMENTS OF FLUCTUATING PRESSURES ON A 1/4-SCALE MODEL OF THE X-1 AIRPLANE WITH A 10-PERCENT-THICK WING IN THE LANGLEY 16-FOOT TRANSONIC TUNNEL.
Louis W. Habel and Seymour Steinberg. January 1953. 29p. diagrs., photos. (NACA RM L52J31)
(Declassified from Confidential, 11-30-54)

Pressure fluctuations have been measured near the trailing edge of the wing and near the leading edge of the tail of a 1/4-scale mode of the X-1 airplane with a 10-percent-thick wing in the Langley 16-foot transonic tunnel. Results are presented for a Mach number range from 0.70 to 1.00 and an angle-of-attack range from about -4° to about 15° with and without vortex generators installed on the wings. Frequency analyses of the pressure fluctuations made while tests were in progress are presented for several test conditions.

NACA RM L52K19
National Advisory Committee for Aeronautics.
AERODYNAMIC CHARACTERISTICS OF TWO DELTA WINGS AT MACH NUMBER 4.04 AND CORRELATIONS OF LIFT AND MINIMUM-DRAG DATA FOR DELTA WINGS AT MACH NUMBERS FROM 1.62 TO 6.9. Edward F. Ulmann and Robert W. Dunning. December 1952. 20p. diagrs. (NACA RM L52K19)
(Declassified from Confidential, 10/29/54)

Tests were made in the Langley 9- by 9-inch Mach number 4 blowdown jet to obtain the aerodynamic characteristics of two semispan delta wings of aspect ratio 2.31 having 8-percent-thick double-wedge airfoil sections and maximum-thickness locations at 18 and 60 percent chord. The data are presented together with the results of previous tests on the same and similar delta wings at other Mach numbers and show methods of correlating lift and drag data on sharp-edge delta wings at supersonic Mach numbers.

CURRENT NACA REPORTS

NACA Rept. 1146

AERODYNAMIC FORCES AND LOADINGS ON SYMMETRICAL CIRCULAR-ARC AIRFOILS WITH PLAIN LEADING-EDGE AND PLAIN TRAILING-EDGE FLAPS. Jones F. Cahill, William J. Underwood, Robert J. Nuber and Gail A. Cheesman. 1953. ii, 38p. diagrs., photos., 5 tabs. (NACA Rept. 1146. Formerly RM L6K22; RM L7H04; RM L50H17a)

A two-dimensional wind-tunnel investigation has been made of 6- and 10-percent-thick symmetrical circular-arc airfoil sections equipped with 0.15-chord plain leading-edge flaps and 0.20-chord plain trailing-edge flaps. The tests consisted of measurements of the aerodynamic forces and surface pressures at low Mach numbers (about 0.15) and several Reynolds numbers (0.7×10^6 to 18×10^6 based on the airfoil chord). A generalized method is developed that permits the determination of the chordwise pressure distribution over sharp-edge airfoils with plain leading- and trailing-edge flaps of arbitrary size and deflection.

NACA Rept. 1149

ON TRANSONIC FLOW PAST A WAVE-SHAPED WALL. Carl Kaplan. 1953. ii, 12p. (NACA Rept. 1149. Formerly TN 2748)

The simplified nonlinear differential equation for transonic flow past a wavy wall is solved by the method of integration in series. A general procedure for the solution of the resulting recurrence formulas is shown and illustrated by a number of examples. A numerical test of convergence is applied to a key power series in k, the transonic similarity parameter, and leads to the conclusion that smooth symmetrical potential flow past the wavy wall is no longer possible when the critical value of the stream Mach number is exceeded.

NACA Rept. 1155

A COMPARISON OF THE EXPERIMENTAL SUBSONIC PRESSURE DISTRIBUTIONS ABOUT SEVERAL BODIES OF REVOLUTION WITH PRESSURE DISTRIBUTIONS COMPUTED BY MEANS OF THE LINEARIZED THEORY. Clarence W. Matthews. 1953. ii, 29p. diagrs., tab. (NACA Rept. 1155. Formerly TN 2519; RM L9F28)

A comparison is made of the theoretical and experimental subsonic compressible pressure-coefficient distributions about several bodies of revolution. The results show that the linearized theory predicts the subsonic pressure coefficients over the central portion of the body. An extrapolation of the theory into the supercritical range does not predict the rearward shift of the negative pressure peak which occurs after the flow becomes critical. Two equations are presented for approximately determining the subsonic compressible pressure-coefficient distributions from the incompressible pressure-coefficient distributions.

NACA Rept. 1158

PREDICTION OF FLAME VELOCITIES OF HYDROCARBON FLAMES. Gordon L. Dugger and Dorothy M. Simon. 1954. ii. 10p. diagrs., 4 tabs. (NACA Rept. 1158. Formerly RM E52J13)

The effects of four combustible-mixture variables on the laminar flame velocities of hydrocarbon-oxygen-nitrogen mixtures are predicted by semitheoretical methods based on (1) Semenov equation (thermal mechanism), (2) Tanford-Pease equation (active-particle-diffusion mechanism), and (3) Manson equation (momentum-pressure-drop equation using active-particle concentrations). A semiempirical factor, calculated from flame velocity data, is required by each of these equations. When these factors are calculated for each variable separately, mean deviations between calculated and measured flame velocities are 2 to 15 percent for the variable studied, namely, hydrocarbon structure, equivalence ratio, oxygen-nitrogen ratio, and initial temperature. When the semiempirical factor for one variable is used to predict the effect of another variable, the mean deviations are approximately doubled. Empirical equations are summarized which give better predictions, but require more constants.

NACA Rept. 1161

AVERAGE SKIN-FRICTION DRAG COEFFICIENTS FROM TANK TESTS OF A PARABOLIC BODY OF REVOLUTION (NACA RM-10). Elmo J. Mottard and J. Dan Loposer. 1954. ii, 7p. diagrs., photos. (NACA Rept. 1161. Formerly TN 2854)

Average skin-friction drag coefficients were obtained from boundary-layer total-pressure measurements on a parabolic body of revolution (NACA RM-10, basic fineness ratio 15) in water at Reynolds numbers from 4.4×10^6 to 70×10^6. The tests were made in the Langley tank No. 1 with the body sting-mounted at a depth of two maximum body diameters. The arithmetic mean of three drag measurements taken around the body was in good agreement with flat-plate results, but, apparently because of the slight surface wave caused by the body, the distribution of the boundary layer around the body was not uniform over part of the Reynolds number range.

NACA TN 3163

USE OF A HOT-WIRE ANEMOMETER IN SHOCK-TUBE INVESTIGATIONS. Darshan Singh Dosanjh, Johns Hopkins University. December 1954. ii, 98p. diagrs., photos. (NACA TN 3163)

The use of the hot-wire anemometer in experimental investigations of the transient flow phenomena in a shock tube is examined. The response of a hot-wire to a transient step-function type of change in flow conditions is experimentally studied and a criterion for predicting the right compensation is postulated and experimentally verified. Besides using the hot-wire for actual wave phenomena and for flow studies, it has been very successfully used as a timing and/or triggering device in shock-tube work.

NACA TN 3317

DESIGN CONSIDERATIONS FOR WINGS HAVING MINIMUM DRAG DUE TO LIFT. Warren A. Tucker. December 1954. 26p. diagrs. (NACA TN 3317)

The problem of increasing the range of supersonic aircraft by the use of twisted and cambered wings is considered, primarily for the purpose of developing a rational method for the selection of a design lift coefficient. Relations and curves are presented from which a suitable selection may be made, depending on the relative importance of maximum range and top speed.

NACA TN 3319

OPERATING CHARACTERISTICS OF AN ACCELERATION RESTRICTOR AS DETERMINED BY MEANS OF A SIMULATOR. Arthur Assadourian. December 1954. 20p. diagrs., photos. (NACA TN 3319)

The operating characteristics of an acceleration restrictor were determined from tests on a simulator consisting of a control stick geared to a magnetic brake unit and an analog computer. The restrictor worked on the principle of stopping the elevator motion by means of a brake when a signal which was a function of normal acceleration, pitching acceleration, and pitching velocity reached a certain preset value. The results obtained with three brake-operating signals are presented.

NACA TN 3321

ANALYTICAL DETERMINATION OF THE MECHANISM OF AN AIRPLANE SPIN RECOVERY WITH DIFFERENT APPLIED YAWING MOMENTS BY USE OF ROTARY-BALANCE DATA. Sanger M. Burk, Jr. December 1954. 43p. diagrs., 2 tabs. (NACA TN 3321)

An analytical investigation has been undertaken in an attempt to learn more about the factors which make up a spin and the mechanism of recovery therefrom. Use is made of rotary-balance data and a step-by-step integration process of Euler's equations of motion allowing six degrees of freedom. The present study makes an analysis of an airplane recovery from a right spin where constant applied antispin yawing moments due to application of 800 and 1,600 pounds of force at the left wing tip are considered.

NACA TN 3327

APPROXIMATE EFFECT OF LEADING-EDGE THICKNESS, INCIDENCE ANGLE, AND INLET MACH NUMBER ON INLET LOSSES FOR HIGH-SOLIDITY CASCADES OF LOW CAMBERED BLADES. Linwood C. Wright. December 1954. 38p. diagrs. (NACA TN 3327)

An approximate analysis of cascade induction loss variations with incidence angle, Mach number, and leading-edge thickness is presented along with computational results in the form of curves. Results are based on the solution of the energy, continuity, and integrated momentum equations under the assumption that the blade leading-edge pressure approaches zero at appreciable incidence angles. Results indicate that relatively small blade leading-edge radii (of the order of 2 percent of blade gap) lead to good inlet characteristics for the average conditions generally encountered in compressors. The desirability of avoiding high stagger angles is indicated by representative inlet loss against incidence angle curves for stagger angles of 45°, 60°, and 75°.

NACA TN 3329

SHOCKS IN HELICAL FLOWS THROUGH ANNULAR CASCADES OF STATOR BLADES. Robert Wasserman and Arthur W. Goldstein. December 1954. 27p. diagrs. (NACA TN 3329)

A method is presented for calculating supersonic potential flows in annular cascades of blades by the method of characteristics. It is found that helical flows may be adjoined by helical shocks of uniform strength; these constitute a considerable addition to the class of simple flows available for designing cascades of lifting blades. It was also found that by selection of the proper variables, the derivatives of the velocity components, which occur in the characteristic equations, could be combined into an exact differential. This form of the equation facilitated computations. A flow and several cascade designs were computed.

NACA TN 3332

BURNING TIMES OF MAGNESIUM RIBBONS IN VARIOUS ATMOSPHERES. Kenneth P. Coffin. December 1954. 37p. diagrs., photos. (NACA TN 3332)

Some details of the mechanism of the combustion of magnesium ribbons were investigated in mixture of oxygen (17 to 100 percent) and inert gases (A, N_2, He, A-H_2O mixtures). Photographs indicated vapor-phase reaction rather than surface reaction. Burning times were calculated for a vapor-phase process with diffusion and heat transfer. Experimental trends were closely predicted; actual numerical values agreed to well within an order of magnitude.

NACA TN 3334

FRICTION OF POSSIBLE SOLID LUBRICANTS WITH VARIOUS CRYSTAL STRUCTURES. Marshall B. Peterson and Robert L. Johnson. December 1954. 32p. diagrs., photos., 2 tabs. (NACA TN 3334)

A number of solids with CdI_2, $CdC1_2$, and MoS_2 types of layer lattice were tested in a low-speed friction apparatus for lubrication effectiveness. Some solids with these structures performed in a manner similar to MoS_2 in that they did lubricate effectively over extended periods of sliding, namely, CdI_2, $CdC1_2$, and PbI_2, $CoC1_2$, and WS_2; other layer-lattice solids that were effective are HgI_2 and Ag_2SO_4. Not all were effective lubricants. Some low-shear-strength solids that did not have a layer lattice were tested and gave surface protection. Effectiveness as a solid lubricant seemed to be associated with the formation of adherent films on both mating specimens.

NACA TN 3354

GUST EXPERIENCE OF A HELICOPTER AND AN AIRPLANE IN FORMATION FLIGHT. Almer D. Crim. December 1954. 12p. diagrs., photos., 2 tabs. (NACA TN 3354)

A single-rotor helicopter and an airplane have been flown in formation in rough air for the purpose of measuring and comparing their responses to gusts. Rough-air flights were also made by the helicopter alone at several different airspeeds over the same ground path.

NACA TN 3379

A SURVEY OF BACKGROUND AND AIRCRAFT NOISE IN COMMUNITIES NEAR AIRPORTS. K. N. Stevens, Bolt Beranek and Newman, Inc. December 1954. 36p. diagrs., tab. (NACA TN 3379)

An extensive survey has been made of background and aircraft noise levels in residential communities in eight cities having major airports. The measurements were made in areas up to a distance of 12 miles from the airports, and the areas were chosen to be under regularly used flight paths. Readings of background noise were obtained primarily in the octave bands 75 to 150, 300 to 600, and 1,200 to 2,400 cps, about 25 such spectra being taken in each area. Octave-band spectra were obtained from magnetic tape recordings of the noise of about 250 aircraft in flight, representing substantially all commercial types.

Royal Aircraft Establishment (Gt. Brit.)
SCALE EFFECTS OF HIGH SUBSONIC AND TRANSONIC SPEEDS, AND METHODS FOR FIXING BOUNDARY-LAYER TRANSITION IN MODEL EXPERIMENTS. A. B. Haines, D. W. Holder and H. H. Pearcey. September 1954. 60p. diagrs., photos. (RAE Tech. Note Aero 2338)

This note is concerned with the major scale effects that arise at high subsonic speeds from the differences between the conditions under which laminar and turbulent boundary layers separate and behave after separation. The scale effects arising in wind tunnel tests made at low Reynolds numbers may often be minimized by fixing transition to turbulent flow by introducing an artificial disturbance such as that producted by excrescences attached to the surface. Several methods which can be used to fix transition are described, and the results obtained by using them are compared.

REQUIREMENTS FOR UNIFORMITY OF FLOW IN SUPERSONIC WIND TUNNELS. D. E. Morris and K. G. Winter. September 1954. 9p. diagr. (RAE Tech. Note Aero 2340)

An analysis is made of the effects of nonuniformity of flow on the pressure measurements on the surface of a model and also on the force and moment measurements, and standards of flow uniformity are derived. A brief analysis is made of the errors in model manufacture and their effects on force and pressure measurements. Using the same standards as were used in deducing the requirements for flow uniformity, it is concluded that present standards of model manufacture are satisfactory overall, though for accurate pressure plotting tests at low supersonic Mach numbers, a higher standard is desirable.

A NOTE ON THE SOUND FROM WEAK DISTURBANCES OF A NORMAL SHOCK WAVE. Alan Powell. April 15, 1954. 10p. diagrs. (ARC 16,728; FM 2062)

The disturbances of a shock wave by sound waves or temperature fluctuations are studied in one dimension to a first order approximation. In general, both sound waves and temperature fluctuations arise behind the shock wave. Expressions are given for their amplitudes, and calculated for $\gamma = 1.4$. Sound waves colliding with the shock wave are amplified, but sound waves are almost annihilated by weak shock waves if originally travelling in the same direction as the shock wave. Small temperature fluctuations give rise to much sound, on an acoustical scale.

Aeronautical Research Council (Gt. Brit.)
DECAY OF TURBULENCE BEHIND A GRID (DYNAMICAL THEORY). D. Meksyn. February 4, 1954. 7p. (ARC 16,530; FM 2019)

It is the purpose of this paper to show that the law of decay of turbulence behind a grid is determined mainly by dynamical connections of the flow, and that it can be obtained by combining the equation of the mean flow with the differential equations for the mean flow. It is shown that the gradual transformation of the linear law of decay of small eddies can be satisfactorily explained and is in general agreement with experimental results.

Aeronautical Research Council (Gt. Brit.)
THOUGHTS ON BOUNDARY LAYER NOISE. Alan Powell. April 15, 1954. 5p. (ARC 16,727; FM 2061)

The problem of boundary-layer noise is discussed as being the predominating noise in high speed aircraft (except in regions intercepting the "cone" of intense jet noise). This boundary-layer noise may be very powerful. The methods by which sound can be generated are considered. In general, the noise arising from the flow past a fixed surface is of complex origin, and the problem has been divided into aerodynamic or "layer noise," surface noise, panting noise, and wake noise.

CALCULATION OF THE LOAD DISTRIBUTION OVER A WING WITH ARBITRARY CAMBER AND TWIST AT SONIC SPEED. K. W. Mangler. August 1954. 55p. diagrs. (RAE Aero 2515)

A method is developed for the calculation of the load distribution due to camber and twist over a thin wing at sonic speed (or, more generally, over wings for which $A^2|M^2-1|$ is small (A aspect ratio, M Mach number)). The calculation is based on the usual assumptions of linearized potential flow without friction and shock waves. Application of the method involves the solution of a given integral equation, which for a general planform has to be solved numerically. Some simple examples show the effect of twist and camber on the load distribution and on the suction force along the leading edge of a delta wing.

THE REMOVAL OF POROSITY FROM INVESTMENT CASE COMPRESSOR BLADES MADE FROM 0.2 PER CENT CARBON, 18 PER CENT CHROMIUM, 2 PER CENT NICKEL STAINLESS STEEL. J. E. Northwood. February 1954. 31p. diagrs., photos., 5 tabs. (NGTE Memo. M. 142)

This Memorandum describes an investigation carried out at the National Gas Turbine Establishment on the elimination of porosity from investment cast 0.2 percent carbon, 18 percent chromium, 2 percent nickel stainless steel. A description is given of attempts to minimize porosity in long thin compressor blades by inducing directional solidification from tip to root. The methods involved the achievement of either a temperature gradient in the mould or a temperature gradient in the freezing metal by the use of chills. An attempt was also made to produce blades by centrifugal casting. All these tests gave unsatisfactory results. A description is given of "pour-out" tests and other work which led to the use of high mould temperatures between 1300° and 1380° C for the satisfactory production of relatively sound castings.

OBSERVATIONS ON THE SURGING OF VARIOUS LOW-SPEED FANS AND COMPRESSORS. A. G. Smith and P. J. Fletcher. July 1954. 30p. diagrs., tab. (NGTE Memo. M. 219)

In the course of testing fans and compressors over a period of years various forms of low disturbances have been noticed at low coefficients. Some of the disturbances were spectacular and a remarkable variation in the type of disturbance was found. This report has been prepared in view of the current interest in surging phenomena. On various fans, four abnormal types of flow have been observed. These abnormal flows have been called "surges" though two of the types did not exhibit the oscillation implied by the name. The commonest surge regime involved the existence of a single band of reverse flow or disturbed flow rotating in the sense of the rotor, but at a lower speed.

A POTASSIUM VAPOUR HOT-CATHODE RECTIFIER. I. A. Mossop. July 1954. 19p. diagrs., photos., tab. (RAE Tech. Note EL. 74)

Alkali vapor diodes, in which the vapor acts both as a conducting gas and as a coating for the cathode, have many features which warrant their consideration for use as power rectifiers in aircraft. An experimental potassium vapor diode has been constructed and its anode characteristics have been measured. Apart from requiring a higher envelope temperature and having a higher arc drop, its performance was found to be similar to that reported in the U. S. A. for a caesium filled tube. A method of presenting a complete anode characteristic, as a cathode ray tube trace, is described; it should be useful for measurements on other heavy current discharge tubes, such as thyratrons. Provision is made for direct calibration of both the voltage and current axes as well as for a simple check on these calibrations and on the linearity of the amplifiers.

ALLOYS OF TITANIUM WITH IRON. D. A. Sutcliffe. July 1954. 15p. diagrs., 8 tabs. (RAE Tech. Note Met.201)

Binary titanium iron alloys containing up to 9.18 percent iron by weight have been prepared by arc melting. Tensile, hardness, and impact tests have been made on the alloys at room temperature. The results show that additions of iron cause a steady increase in hardness and strength with a corresponding loss in ductility. An alloy containing 3.0 percent iron had a Vickers hardness of 242 D. P. N.; a U. T. S. of 45.6 tons/sq inch and a percent elongation of 24; the impact strength as determined on Izod specimens of substandard size was 3.7 ft-lbs (approximately half that of the basis titanium). A survey of the literature is included and details are given of the published work on the titanium iron phase diagram and the effect of iron on the mechanical properties of titanium.

STRESS ANALYSIS OF MULTI-WEB BOXES. W. S. Hemp. March 21, 1954. 18p. diagrs. (ARC 16,767; Strut 1706)

Particular solutions given are constant stress solution, pure shear solution, bending by tip shear force, distributed pressure, and anti-symmetric internal stress system (root constraint in torsion). These particular solutions are incomplete and have to be supplemented by the solutions of problems formulated in given equations. Solutions to these supplementary problems are best obtained by approximate methods using Castigliango's Theorem of Stationary Strain Energy. An example is worked out for root constraint for the case of tip shear force.

THE HOT-WIRE ANEMOMETER FOR TURBULENCE MEASUREMENTS. PART IV. B. Wise and D. L. Schultz. April 15, 1954. 42p. diagrs. (ARC 16,726; FM 1527c; Oxford Univ., Engineering Lab. No. 71)

An account is given of some measurements of both turbulence level and spectra at subsonic and supersonic speeds. An investigation of the steady-state heat-loss law over the transonic range is also described.

N-34503*

Aeronautical Research Council (Gt. Brit.)
THERMO-ELASTICITY. W. S. Hemp. April 1954. 8p. (ARC 16,766; Strut. 1683)

A continuous solid body is referred to rectangular axes. The body is assumed "elastic"; that is, the components of strain are taken to be single valued functions of the components of stress and the temperature T. The body is subjected to a quasi-static loading by forces (X, Y, Z) per unit volume and (X_V, Y_V, Z_V) per unit of external surface. The temperature T' of the surrounding medium at the surface of the body and the "heat transfer coefficient" or "external conductivity" h is assumed to be known. Both the mechanical and thermal loading are varied with the time t, but not so rapidly as to excite vibration in the body. The problem solved is the calculation of the deformation, stress, and temperature distribution as functions of the time.

NOTES ON HELICOPTER FLIGHT RESEARCH. John P. Reeder. (Presented to Flight Test Panel of Advisory Group for Aeronautical Research and Development, Paris, France, November 29 - December 4, 1954) 29p. diagrs., photos.

The NACA entered the field of rotary-wing research and flight testing some 23 years ago with studies of the autogiro. This experience served as a background for helicopter research and the first helicopter was received for flight testing in 1944. This paper briefly reviews some of the knowledge gained from flight tests. One problem studied is that of blade stalling. More recently the study of the flying qualities of a helicopter has been undertaken. This has included speed stability, maneuver stability, and turn and lateral-oscillation characteristics. Other current projects include instrument flying studies and the helicopter loads program.

N-33814*

THE STATUS OF RESEARCH IN THE FIELD OF HEAT TRANSFER. E. Schmidt. June 1954. 31p. diagrs., photos. (Trans. from Zeitschrift des Vereines deutscher Ingenieure, v. 76, no. 42, October 15, 1932, p. 1025-1032)

The complexity of the field of heat transfer and its problems is discussed. Theory succeeds in presenting complete solutions for only a few simple cases. A summary is given of the measuring methods and results in the most important individual cases of heat transfer. Questions not yet clarified and problems to be dealt with in the future are pointed out. We shall have to make a strenuous effort in order to maintain the lead Germany has had so far in view of the fact that in America much emphasis is being placed on problems of heat transfer.

CURRENT NACA REPORTS

NACA Rept. 1143

A VECTOR STUDY OF LINEARIZED SUPERSONIC FLOW APPLICATIONS TO NONPLANAR PROBLEMS. John C. Martin. 1953. ii, 34p. diagrs., tab. (NACA Rept. 1143. Formerly TN 2641)

A vector study of the partial-differential equation of steady linearized supersonic flow is presented. General expressions are derived which relate the velocity potential in the stream to the conditions on the disturbing surfaces. Problems concerning nonplanar systems are investigated, and methods are derived for the solution of some simple problems. The damping in roll is found for rolling tails consisting of four, six, and eight rectangular fins.

NACA Rept. 1152

THEORY AND PROCEDURE FOR DETERMINING LOADS AND MOTIONS IN CHINE-IMMERSED HYDRODYNAMIC IMPACTS OF PRISMATIC BODIES. Emanuel Schnitzer. 1953. ii, 29p. diagrs. (NACA Rept. 1152. Formerly TN 2813)

A theoretical method is derived for computing the motions and hydrodynamic loads during water landings of prismatic bodies involving appreciable immersion of the chines. A simplified method of computation covering flat-plate and V-bottom bodies with beam-loading coefficients greater than unity is given as a separate section. Comparisons of theory with experiment are presented as plots of impact lift coefficient and maximum draft-beam ratio against flight-path angle and as time histories of loads and motions. Fair agreement is found to exist for chine-immersed landings for angles of dead rise of 0° and 30°, beam-loading coefficients from 1 to 36.5, flight-path angles from 2° to 90°, and trims from 6° to 45°.

NACA Rept. 1154

ANALYSIS OF LANDING-GEAR BEHAVIOR. Benjamin Milwitzky and Francis E. Cook. 1953. iii, 45p. diagrs., photo., 3 tabs. (NACA Rept. 1154. Formerly TN 2755)

The behavior of the conventional oleo-pneumatic landing gear during impact is analyzed. The applicability of the analysis to actual landing gears is established by comparing calculated results with drop-test data. In addition to the more exact treatment, studies are made to determine the effects of variations in such parameters as the force-deflection characteristics of the tire, the orifice discharge coefficient, and the polytropic exponent for the air-compression process in the shock strut, which may not be known accurately in practical design problems. An investigation is also made to determine the extent to which representation of the system can be simplified and still yield useful results. Generalized solutions for the behavior of a simplified system, which may be useful in preliminary design, are presented for a wide range of landing-gear and impact parameters.

NACA Rept. 1159

IMPINGEMENT OF WATER DROPLETS ON WEDGES AND DOUBLE-WEDGE AIRFOILS AT SUPERSONIC SPEEDS. John S. Serafini. 1954. ii, 24p. diagrs. (NACA Rept. 1159. Formerly TN 2971)

An analytical solution has been obtained for the equations of motion of water droplets impinging on a wedge in a two-dimensional supersonic flow field with a shock wave attached to the wedge. The closed-form solution yields analytical expressions for the equation of the droplet trajectory, the local rate of impingement and the impingement velocity at any point on the wedge surface, and the total rate of impingement. The analytical expressions are utilized to determine the impingement on the forward surfaces of diamond airfoils in supersonic flow fields with attached shock waves. The results presented include the following conditions: droplet diameters from 2 to 100 microns, pressure altitudes from sea level to 30,000 feet, free-stream static temperatures from 420° to 460° R, free-stream Mach numbers from 1.1 to 2.0, semiapex angles for the wedge from 1.14° to 7.97°, thickness-to-chord ratios for the diamond airfoil from 0.02 to 0.14, chord lengths from 1 to 20 feet, and angles of attack from zero to the inverse tangent of the airfoil thickness-to-chord ratio.

NACA RM A54I23

A HEATED-WIRE LIQUID-WATER-CONTENT INSTRUMENT AND RESULTS OF INITIAL FLIGHT TESTS IN ICING CONDITIONS. Carr B. Neel. January 1955. 33p. diagrs., photos., tab. (NACA RM A54I23)

A flight model of the heated-wire instrument was tested in natural icing conditions, and was shown to provide reliable measurements of liquid-water content. The rapid response of the instrument enabled detailed study of cloud structure. Cloud-duct tests showed measurements could be made up to 700 mph. Results of the flight measurements substantiated the high values of water content previously predicted. The highest value measured was 3.7 grams per cubic meter.

NACA TM 1354

GENERAL THEORY OF CONICAL FLOWS AND ITS APPLICATION TO SUPERSONIC AERODYNAMICS. (La théorie générale des mouvements coniques et ses applications a l'aérodynamique supersonique). Paul Germain. PREFACE. M. J. Peres. January 1955. vii, 333p. diagrs. (NACA TM 1354. Trans. from Office National d'Études et de Recherches Aéronautiques, Pub. 34, 1949)

The report deals with a method of studying the equation of cylindrical waves particularly indicated for the solution of certain aerodynamic problems. The method reduces problems of a hyperbolic equation to problems of harmonic functions. The study has been applied toward setting up the fundamental principles, to developing their investigation up to calculation of the pressures on the visualized obstacles, and to showing how the initial field of "conical flows" was considerably enlarged by a procedure of integral superposition.

NACA TN 3149

PREDICTION OF LOSSES INDUCED BY ANGLES OF ATTACK IN CASCADES OF SHARP-NOSED BLADES FOR INCOMPRESSIBLE AND SUBSONIC COMPRESSIBLE FLOW. James J. Kramer and John D. Stanitz. January 1955. 45p. diagrs. (NACA TN 3149)

A method of computing the losses in total pressure caused by a nonzero angle of attack at the inlet to a row of sharp-nosed blades is developed for both incompressible and subsonic compressible flow. The results of the analysis indicate for the range of variables considered that increases in upstream flow angle cause sharp rises in total-pressure loss coefficient and corresponding drops in static-pressure coefficient for negative angles of attack, but for positive angles of attack and upstream flow angles less than 60° there is little variation in total-pressure loss coefficient with upstream flow angle.

NACA TN 3264

STUDY OF THE MOMENTUM DISTRIBUTION OF TURBULENT BOUNDARY LAYERS IN ADVERSE PRESSURE GRADIENTS. Virgil A. Sandborn and Raymond J. Slogar. January 1955. 79p. diagrs., photos. (NACA TN 3264)

Experimental evaluation and analysis were made of mean and turbulent terms of the equations of motion and the stress tensor at four stations in a turbulent boundary layer with a progressively increasing adverse pressure gradient. Evaluation of terms of the stress tensor indicated that $\rho\overline{v^2}$, $\rho\overline{w^2}$, and $-\rho\overline{uv}$ are of equal order of magnitude, while $\rho\overline{u^2}$ is roughly four times larger near the wall. The term $\frac{\partial \overline{v^2}}{\partial y}$ of the y-direction equation of motion was found to be as large as any term of the x-direction equation.

NACA TN 3266

EXPERIMENTAL EVALUATION OF MOMENTUM TERMS IN TURBULENT PIPE FLOW. Virgil A. Sandborn. January 1955. 40p. diagrs. (NACA TN 3266)

Terms of the longitudinal- and radial-direction turbulent momentum equations were experimentally evaluated in a 4-inch-diameter pipe from total- and static-pressure data and hot-wire anemometer surveys. Terms of the r-direction momentum equation were found to be as large as terms of the x-direction equation. Direct comparisons were made with turbulence measurements obtained using the constant-current and constant-temperature systems of hot-wire anemometry. The two systems agree equally well within the experimental accuracy of the measurements.

NACA TN 3311

DESCRIPTION AND ANALYSIS OF A ROCKET-VEHICLE EXPERIMENT ON FLUTTER INVOLVING WING DEFORMATION AND BODY MOTIONS. H. J. Cunningham and R. R. Lundstrom. January 1955. 26p. diagrs., photos., 2 tabs. (NACA TN 3311. Formerly RM L50I29)

Flight tests and a mathematical analysis were carried out to demonstrate and confirm a type of subsonic flutter involving rigid-body motions and wing deformations. For the configuration considered, the period of the oscillation was approximately 100 chords per cycle which is well within the range of period found in dynamic-stability work on rigid aircraft with free controls. A mathematical analysis based on two-dimensional incompressible flow provided a conservative prediction of the airspeed at which the low-frequency flutter occurred. Wing-bending stiffness is the important parameter for preventing such flutter.

NACA TN 3318

ON THE SMALL-DISTURBANCE ITERATION METHOD FOR THE FLOW OF A COMPRESSIBLE FLUID WITH APPLICATION TO A PARABOLIC CYLINDER. Carl Kaplan. January 1955. 36p. diagrs., tab. (NACA TN 3318)

The Prandtl-Busemann small-disturbance method is applied to a parabolic cylinder and compared with the Janzen-Rayleigh or M_{∞}^2-expansion solution for the same shape. As expected, the small-disturbance and M_{∞}^2-expansion developments are but two different arrangements of the actual solution. Notwithstanding this agreement, it is concluded that the curtailed small-disturbance solution is not suitable for the calculation of subsonic flow past a shape (like the parabolic cylinder) which does not possess a control parameter such as, for example, a thickness coefficient. The small-disturbance solution for the parabolic cylinder is examined from the point of view of thin-airfoil theory. The series development of the fluid speed at the surface in powers of the ratio of the radius of curvature of the vertex and the abscissa measured from the vertex agrees with the results of second-order thin-airfoil theory.

NACA TN 3323

CHARTS FOR ESTIMATING PERFORMANCE OF HIGH-PERFORMANCE HELICOPTERS. Alfred Gessow and Robert J. Tapscott. January 1955. 36p. diagrs. (NACA TN 3323)

Theoretically derived charts are presented for use in predicting profile-drag—thrust ratios of rotors having hinged blades with -8° twist. The charts are considered applicable to rotor-operating conditions

in which high tip-speed ratios or large rotor angles of attack are encountered; however, they do not include the effects of compressibility. Limit lines showing the conditions of onset of stall are included in the charts, and the effects of blade twist on the stall limits are discussed.

NACA TN 3324

A NOTE ON THE DRAG DUE TO LIFT OF RECTANGULAR WINGS OF LOW ASPECT RATIO. Edward C. Polhamus. January 1955. 24p. diagrs. (NACA TN 3324)

Methods of estimating the induced drag of low-aspect-ratio wings are discussed and compared with experiment. The profile drag due to lift is also discussed and a method is developed which relates the effect of aspect ratio on the profile drag due to lift to an "effective" two-dimensional lift coefficient. A simple expression for this effective two-dimensional lift coefficient in terms of the aspect ratio is derived and used to correlate experimental values of profile drag due to lift for rectangular wings in the low-aspect-ratio range.

NACA TN 3331

ANALYSIS OF LAMINAR FORCED-CONVECTION HEAT TRANSFER IN ENTRANCE REGION OF FLAT RECTANGULAR DUCTS. E. M. Sparrow. January 1955. 42p. diagrs. (NACA TN 3331)

The simultaneous development of temperature and velocity profiles in the entrance region of a flat rectangular duct is studied. The flow is laminar with constant properties and negligible dissipation. Two thermal conditions for the duct walls are considered: (1) both walls have the same uniform temperature throughout; (2) one wall is at uniform temperature, the other wall is insulated. Thermal and velocity boundary layers are calculated using the Kármán-Pohlhausen method. Nusselt numbers are reported for Prandtl number in the range 0.01 to 50. For simultaneously developing profiles, the Nusselt number is found not to be a function at Graetz number alone, as it is for an unchanging parabolic velocity profile throughout.

NACA TN 3335

METHODS FOR RAPID GRAPHICAL EVALUATION OF COOLED OR UNCOOLED TURBOJET AND TURBOPROP ENGINE OR COMPONENT PERFORMANCE (EFFECTS OF VARIABLE SPECIFIC HEAT INCLUDED). Jack B. Esgar and Robert R. Ziemer. January 1955. 45p. diagrs. (NACA TN 3335)

Curves based on the thermodynamic properties of air and combustion gases for a hydrogen-carbon ratio of 0.167 are presented to relate parameters affecting each engine component. The curves cover a range of flight Mach numbers from 0 to 3.0, compressor pressure ratios from 1 to 30, turbine-inlet temperatures from 1500° to 3000° R, and afterburner temperatures from 2800° to 3500° R. Except for extreme cases, the curves are accurate to at least 3° R in temperature and 1 percent in pressure ratio, fuel-air ratio, and specific thrust. Procedures required for performance evaluation are explained for both uncooled engines with no compressor bleed and for engines utilizing both compressor bleed and turbine cooling.

NACA TN 3337

INVESTIGATION OF TEMPERATURE LIMITATION OF VARIOUS LUBRICANTS FOR HIGH-TEMPERATURE 20-MILLIMETER-BORE BALL BEARINGS. Z. N. Nemeth and W. J. Anderson. January 1955. 31p. diagrs., photos., 2 tabs. (NACA TN 3337)

Twenty-millimeter-bore tool-steel ball bearings, equipped with either a beryllium copper or an Inconel cage, were operated with liquid and with solid lubricants at temperatures from 100° to 1000° F at a speed of 2500 rpm and a thrust load of 110 lb. Solid lubricants were more effective than fluid lubricants at the higher temperatures. Graphite provided effective lubrication to 1000° F with bearings equipped with either a beryllium copper or an Inconel cage; molybdenum disulfide, to 850° F with a bearing equipped with an Inconel cage. A silicone-diester blend, the best high-temperature liquid lubricant, provided effective lubrication to 700° F and allowed operation of the bearing at 850° F although the bearing operation was rough and friction torque was high.

NACA TN 3346

PREDICTION OF DOWNWASH BEHIND SWEPT-WING AIRPLANES AT SUBSONIC SPEED. John DeYoung and Walter H. Barling, Jr. January 1955. 104p. diagrs., 3 tabs. (NACA TN 3346)

The numerical integration method presented enables a rapid prediction of downwash. The principal effects of the rolling-up of the wake are treated as corrections to the flat-sheet wake. A simple approximate correction for the effect of the fuselage is applied. Computing forms and charts of pertinent functions are included. Agreement with available experimental data is good.

NACA TN 3353

EFFECTIVE MOMENT OF INERTIA OF FLUID IN OFFSET, INCLINED, AND SWEPT-WING TANKS UNDERGOING PITCHING OSCILLATIONS. James R. Reese and John L. Sewall. January 1955. 27p. diagrs., 6 tabs. (NACA TN 3353)

Fluid-dynamics studies were made of simplified model fuel tanks undergoing pitching oscillations. The tanks were pylon mounted, centrally mounted at angles of sweep, and inclined at angles of attack. The effective moment of inertia of the fluid was determined experimentally for the various tank configurations over a tank-fullness range from empty to full. For full pylon-mounted and swept-wing tanks, comparisons of experimental and theoretical solutions for the effective moment of inertia of fluid showed good agreement. Studies of the effect of vertical, horizontal, and diffused baffles in pylon-mounted tanks showed that the effective moment of inertia of the fluid was considerably less without baffles. Diffused baffles were found to have high damping characteristics in pylon-mounted tanks and very low damping characteristics in centrally mounted tanks.

NACA TN 3356

EFFECT OF LAG OF SIDEWASH ON THE VERTICAL-TAIL CONTRIBUTION TO OSCILLATORY DAMPING IN YAW OF AIRPLANE MODELS. Lewis R. Fisher and Herman S. Fletcher. January 1955. 38p. diagrs., photos. (NACA TN 3356)

Two models were tested which permitted, in effect, a systematic variation of the sidewash gradient at the vertical tail. For the first model, this variation was accomplished by mounting auxiliary fins forward of the vertical tail; for the second model, it was done by altering the vertical location of the wing on the fuselage. The unsteady damping-in-yaw and directional-stability parameters are compared with the steady derivatives obtained for the same models to establish the effects of the sidewash and the lag of the sidewash on these lateral stability derivatives.

NACA TN 3357

THE EFFECTS OF VARIOUS PARAMETERS, INCLUDING MACH NUMBER, ON PROPELLER-BLADE FLUTTER WITH EMPHASIS ON STALL FLUTTER. John E. Baker. January 1955. 40p. diagrs., 3 tabs. (NACA TN 3357. Formerly RM L50L12b)

The effect of many parameters significant to wing flutter as well as blade twist was studied on several untwisted rotating models to determine their significance with respect to propeller stall flutter. The minimum values of the flutter-speed coefficient were found to be slightly greater than 1.0 at subcritical Mach numbers. Of the few parameters that raised the minimum flutter-speed coefficients, forward movement of the section center-of-gravity location and Mach number at supercritical speeds were most significant. The effect of Mach number was of such significance that a tentative criterion for designing completely flutter-free thin supersonic propellers is indicated.

NACA TN 3360

SOME EFFECTS OF PROPELLER OPERATION AND LOCATION ON ABILITY OF A WING WITH PLAIN FLAPS TO DEFLECT PROPELLER SLIPSTREAMS DOWNWARD FOR VERTICAL TAKE-OFF. John W. Draper and Richard E. Kuhn. January 1955. 28p. diagrs., photo. (NACA TN 3360)

An investigation has been conducted of the effects of propeller blade angle, mode of propeller rotation, propeller location, and ratio of wing chord to propeller diameter on the ability of a wing with plain flaps to deflect the propeller slipstream downward in order to achieve vertical take-off. The basic model consisted of a semispan wing with 30-percent-chord and 60-percent-chord plain flaps. Two large-diameter overlapping propellers driven by electric motors were used.

NACA TN 3361

AERODYNAMIC CHARACTERISTICS OF NACA 0012 AIRFOIL SECTION AT ANGLES OF ATTACK FROM 0° TO 180°. Chris C. Critzos, Harry H. Heyson and Robert W. Boswinkle, Jr. January 1955. 21p. diagrs. (NACA TN 3361)

The aerodynamic characteristics of the NACA 0012 airfoil section are presented for an angle-of-attack range extending through 180°. Data were obtained at a Reynolds number of 1.8×10^{6} with the airfoil surfaces smooth and with roughness applied at the leading and trailing edges and at a Reynolds number of 0.5×10^{6} with the airfoil surfaces smooth. The tests were conducted in the Langley low-turbulence pressure tunnel at Mach numbers no greater than 0.15.

NACA TN 3364

INVESTIGATION OF EFFECTIVENESS OF LARGE-CHORD SLOTTED FLAPS IN DEFLECTING PROPELLER SLIPSTREAMS DOWNWARD FOR VERTICAL TAKE-OFF AND LOW-SPEED FLIGHT. Richard E. Kuhn and John W. Draper. January 1955. 42p. diagrs., photo., tab. (NACA TN 3364)

An investigation of the effectiveness of a wing equipped with large-chord slotted flaps and an auxiliary vane in rotating the effective thrust vector of propellers to a near-vertical direction for vertical take-off and low-speed flight has been conducted. The model consisted of a semispan wing equipped with 60-percent-chord and 30-percent-chord slotted flaps. Two large-diameter overlapping propellers, driven by electric motors, were used. The effect of wing incidence, propeller blade angle, and an auxiliary vane on the ability of the wing equipped with slotted flaps to deflect the propeller slipstreams downward were also investigated. A few tests covered an angle-of-attack range from 0° to 90° and a thrust-coefficient range representing free-flight velocities from zero to the normal range of cruising velocity.

NACA TN 3366

A METHOD FOR STUDYING THE TRANSIENT BLADE-FLAPPING BEHAVIOR OF LIFTING ROTORS AT EXTREME OPERATING CONDITIONS. Alfred Gessow and Almer D. Crim. January 1955. 27p. diagrs. (NACA TN 3366)

A method is presented for studying the transient behavior of the flapping motion, as well as for calculating the steady-state flapping amplitudes, of free-to-cone and seesaw rotors operating at extreme flight conditions. The method is general and can be applied to blades of any airfoil section, mass distribution, twist, plan-form taper, root cutout, and flapping-hinge geometry. Stall and compressibility effects can also be accounted for. Applications of the method to the calculation of the stability of the flapping motion of unloaded rotors and to the transient blade motion resulting from arbitrary control inputs under conditions of extreme stall are included.

NACA TN 3387

USE OF NONLINEARITIES TO COMPENSATE FOR THE EFFECTS OF A RATE-LIMITED SERVO ON THE RESPONSE OF AN AUTOMATICALLY CONTROLLED AIRCRAFT. Stanley F. Schmidt and William C. Triplett. January 1955. 27p. diagrs., tab. (NACA TN 3387)

A method is developed for designing suitable nonlinear functions of error into a system to compensate for the undesirable effects of control-surface rate limiting on the response of an automatically controlled aircraft.

BRITISH REPORTS

N-34602*

Aeronautical Research Council (Gt. Brit.)
THE EFFICIENCY OF HIGH-SPEED WIND TUNNELS OF THE INDUCTION TYPE. A. E. Knowler and D. W. Holder. APPENDIX - THE EFFICIENCY OF INTERMITTENT OPERATION FROM COMPRESSED AIR STORAGE. D. W. Holder. 1954. iii, 59p. diagrs., photo., 6 tabs. (ARC R & M 2448. Formerly ARC 7563; 7672; 7756; 7812; 8024; 8138; 8394; 8668; 8669; 8670; 9490 and 9902)

An investigation has been made of the influence of various design features upon the efficiency of an induction-type tunnel with an annular injector slot. A model tunnel of circular cross-section was used, the working-section diameter being 2-1/4 inch. At subsonic working-section speeds it was found that efficiencies comparable with those of direct-action tunnels could be attained, but at supersonic speeds the efficiency began to fall rapidly. A comparison between the 2-1/4 inch and 12 inch tunnels is made.

ASSESSMENT OF THE RELATIVE PERFORMANCE OF THE BY-PASS ENGINE AND THE ORTHODOX DOUBLE COMPOUND JET ENGINE. E. A. Bridle. 1954. 12p. diagrs. (ARC R & M 2862; ARC 11,740. Formerly NGTE Memo. M. 32)

The by-pass engine can be described as a form of ducted fan engine in which the fan boosts the main compressor. Two possible forms of by-pass engine are described, and their estimated performance is compared with that of the orthodox double compound jet engine under various flight conditions, the calculations being extended to include the case of thrust boosting by means of exhaust reheat. It is concluded that the by-pass engine can offer an appreciable gain in respect of fuel economy over the orthodox double compound jet engine even at 650 mph in the stratosphere, at the expense, however, of increased frontal area for a given thrust.

FULL-SCALE MEASUREMENTS OF IMPACT LOADS ON A LARGE FLYING BOAT. PART 1. DESCRIPTION OF APPARATUS AND INSTRUMENT INSTALLATION. J. W. McIvor. 1954. 27p. photos., diagrs. (ARC CP 182)

The variations with time of the total force and the distribution of water pressures on the hull bottom of a flying boat are related to the horizontal velocity, vertical velocity and keel attitude relative to the water during impact. Methods are described for obtaining, in a form suitable for easy analysis of results, records of these variables, in order to verify impact theories. The equipment used included transducers for the conversion of physical quantities to electrical signals, multichannel electronic amplifiers, and mirror galvanometer recorders.

THE EFFECT OF INLET CONDITIONS ON THE FLOW IN ANNULAR DIFFUSERS. I. H. Johnston. 1954. 15p. diagrs. (ARC CP 178)

Tests have been carried out on annular diffusers having a common area ratio of 3.19 and varying in divergence angle from 6.5° to 15°. The performance of each diffuser has been measured for a variety of inlet velocity distributions and the effect of axially splitting the flow in the diffusers has been investigated. Diffuser efficiency is found to deteriorate as inlet conditions become nonuniform, this tendency increasing with diffuser angle. Splitting of the higher angle diffusers improves efficiency for nonuniform profiles, but these increases in efficiency are accompanied by pronounced static pressure gradients across the diffuser throat which in certain applications might prove undesirable.

A METHOD OF COMPUTING SUBSONIC AND TRANSONIC PLANE FLOWS. C. S. Sinnott. 1954. 21p. diagrs., photos. (ARC CP 173)

A relaxation treatment of a simple but exact differential equation for compressible flow is presented. The method has advantages over other numerical treatments of the same problem and because of the simplicity of the basic differential equation should be particularly suitable for high-speed computing machines. The flow about a 10-percent-thick airfoil (RAE 104) at zero incidence is calculated for Mach numbers fo 0.70, 0.79, and 0.86. At M = 0.86 the existence, but not the position of a transonic shock wave is predicted by the relaxation technique. Satisfactory agreement with experiment is obtained.

THE THEORETICAL INTERFERENCE VELOCITY ON THE AXIS OF A TWO-DIMENSIONAL WIND TUNNEL WITH SLOTTED WALLS. R. C. Tomlinson. 1954. 15p. diagrs., 2 tabs. (ARC CP 181)

A calculation is made of the interference velocity on the axis in the flow of an incompressible fluid past a line doublet in a two-dimensional slotted-wall tunnel, i.e. a rectangular tunnel whose shorter sides are slotted in the direction on the flow. Numerical solutions are obtained which show that if the width of (slot + slat) is one twelfth of the tunnel height (e.g. six slots in the shorter side of a 2 by 1 tunnel), the interference velocity is little different from the corresponding open-jet value - i.e. no slats - for all slot/slat ratios greater than 1/40. It appears likely that all cases which give conditions uniform across the center plane of the tunnel will also give an interference velocity which is close to the open jet figure.

THE M. A. E. E. RECORDING ACCELEROMETER. D. M. Ridland and R. Parker. 1954. 20p. photos., diagrs. (ARC CP 177)

The M. A. E. E. recording accelerometer is basically the accelerometer unit of a desynn accelerometer, adapted to make a continuous and immediate presentation of accurate, calibrated accelerations on a half second time base. The recording medium is metallized paper, having a speed of half an inch per second, and the instrument can be operated continuously for 20 minutes on one loading. It can record with full scale deflections, from 1 to 10gg when the natural frequencies will be about 7 and 22 cps, respectively. The instrument is simple, it has been proved reliable and accurate and is most convenient in use.

THERMODYNAMIC PROPERTIES OF AIR AND COMBUSTION PRODUCTS OF HYDROCARBON FUELS. PART III. THE FLOW OF GASES OF VARYING SPECIFIC HEAT. D. Fielding, J. E. C. Topps and W. R. Thomson. June 1954. 43p. diagrs. (NGTE R. 160)

General methods of calculating gas flow have been investigated and it has been found possible to present data in graphical form which permits the frictionless flow properities of ideal gases of varying specific heat and any molecular weight to be calculated at velocities up to sonic with error not exceeding that inherent in the approximation to four significant figures. Charts are presented of a total head flow parameter against pressure ratio, pressure ratio against temperature ratio, and Mach number against temperature ratio, all with molar specific heat as a running parameter. The relations are also given for Mach numbers 1.0 to 3.0.

TESTS TO DETERMINE THE EFFECT OF THE EXHAUST CONE SUPPORT STRUT FAIRINGS ON THE PERFORMANCE OF A TURBO-JET ENGINE. W. Deacon. July 1954. 19p. diagrs. (NGTE Memo. M. 222)

Simple bench tests have been made to determine what effect the exhaust cone support strut fairings have on the performance of a turbojet engine. Pitot and yawmeter traverses were made just downstream of the turbine. The results show that some residual swirl is present in the turbine exhaust, and that the fairings effectively remove it. Removal of the strut fairings causes an increase in exhaust losses, mainly due to the increased swirl in the exhaust system, but also due to the exposure of unfaired support rods. The increased loss due to swirl is in accordance with that predicted from model tests. When the fairings are removed, removal of the bullet causes no further increase in exhaust losses.

Nat. Gas Turbine Establishment (Gt. Brit.)
SOME CALCULATIONS ON IDEAL COMBUSTION IN A PARALLEL DUCT. A. B. P. Beeton. July 1954. 25p. diagrs. (NGTE Memo. M. 221)

Taking one typical case representative of ram-jet combustion conditions, calculations were made of the integrated kinetic energy and throat specific impulse after loss-free combustion in a parallel duct. Various inlet flow velocities were considered, corresponding to downstream throat areas between 83-1/2 percent and 95-1/2 percent of the duct area. Comparing these results with those calculated for the same approach velocities on the usual basis of homogeneous flow, the latter are shown to involve a loss in specific impulse of at most half a second in 150. The corresponding kinetic energies were not calculated with sufficient accuracy to obtain more than the order of the loss, which appeared to be about half the energy in the approach flow.

Nat. Gas Turbine Establishment (Gt. Brit.)
THE EFFECT OF BURNER SHROUD AIR ON A FUEL SPRAY. H. Clare. July 1954. 25p. diagrs., photos. (NGTE Memo. M. 223)

The possibility of using shroud air as an atomization booster has been investigated. It was found to be effective only when the initial spray was coarse. Drop size analyses of sprays produced from swirl atomizers at low fuel pressures showed that at low shroud air pressure swirling air was the more effective. At higher air pressures of 20 in. water the effects of both swirled and unswirled air were similar. The difference between the swirled and unswirled air was most marked at a pressure of 2 in. head of water where the swirling air improved atomization, whilst unswirled air produced a still coarser spray. It is concluded that swirling shroud air could be used to advantage where both fuel and shroud air pressures were low, a condition which might be expected in an aircraft combustion chamber idling at altitude.

A CORRECTED SPEED TACHOSCOPE. R. Staniforth. May 1954. 15p. diagrs., photos. (NGTE Memo. M.217)

It is often desirable in testing aerodynamic compressors to take all readings at fixed corrected speeds rather than true speeds. This corrected speed is defined as the actual shaft speed divided by the square root of the ratio of the absolute air inlet temperature to the standard temperature (288° K.). With the instrument described, this is possible with high accuracy (error < 0.1 percent) without further complication than the setting of a dial to the observed air inlet temperature. The latter operation could be dispensed with and the correction obtained directly from a temperature sensitive device such as a thermistor or a resistance thermometer element.

Marine Aircraft Experimental Establishment (Gt. Brit.) SOME ASPECTS OF THE FLOW ROUND PLANING SEAPLANE HULLS OR FLOATS AND IMPROVEMENT IN STEP AND AFTERBODY DESIGN. K. M. Tomaszewski and A. G. Smith. September 1954. 13p. diagrs., photo. (MAEE F/TN/4; ARC 14,376; ARC S. 669. Formerly MAEE Tech. Memo 5)

A method of step and afterbody design is given and illustrated which is based on knowing the shape of the wake produced by the forebody and the interaction

between air and water flow under the afterbody. It is claimed that this is a logical approach which gives the designer a clear overall picture of the physical conditions existing during take-off and landing, enabling the optimum aero- and hydrodynamic performance to be quickly obtained. Application leads to large improvements in air and water drag and in water stability.

DECLASSIFIED NACA REPORTS

NACA RM L7L12

MEASUREMENTS OF THE WING AND TAIL LOADS DURING THE ACCEPTANCE TESTS OF BELL XS-1 RESEARCH AIRPLANE. De E. Beeler and John P. Mayer. April 13, 1948. 25p. diagrs., photos., 2 tabs. (NACA RM L7L12) (Declassified from Confidential, 12/10/54)

During the acceptance tests of the XS-1 airplane, strain-gage measurements were made of wing and tail loads up to a Mach number of 0.80. The maximum lift and buffet boundaries were also determined. The loads encountered were well within the design loads and showed fairly good agreement with wind-tunnel and calculated data.

NACA RM L8A09

GENERAL HANDLING-QUALITIES RESULTS OBTAINED DURING ACCEPTANCE FLIGHT TESTS OF THE BELL XS-1 AIRPLANE. Walter C. Williams, Charles M. Forsyth and Beverly P. Brown. April 19, 1948. 72p. diagrs., photos., tab. (NACA RM L8A09) (Declassified from Confidential, 12/10/54)

Presents results obtained during acceptance tests of the Bell XS-1 airplane from minimum speed to a Mach number of 0.8. The longitudinal stability was positive but low for all conditions tested. The directional stability was exceptionally high, and the lateral stability was positive throughout the speed range tested. Aileron control was adequate. The stalling characteristics were considered satisfactory with stall warning in the form of buffeting. The large amount of friction in the control system, coupled with low control-operating forces, made exact control of the airplane difficult.

NACA RM L50J27

STABILITY AND CONTROL CHARACTERISTICS OF A 1/4-SCALE BELL X-5 AIRPLANE MODEL IN THE LANDING CONFIGURATION. Robert E. Becht. December 18, 1950. 38p. diagrs., photos. (NACA RM L50J27) (Declassified from Confidential, 10/29/54)

An investigation was conducted to determine the stability and control characteristics of a 1/4-scale model of a preliminary Bell X-5 airplane design in the landing configuration with and without dive brakes. Tests were made at wing sweep angles of 20° and 60°.

NACA RM L50K30

THE ORIGIN OF AERODYNAMIC INSTABILITY OF SUPERSONIC INLETS AT SUBCRITICAL CONDITIONS. Antonio Ferri and Louis M. Nucci. January 26, 1951. 111p. diagrs., photos., tab. (NACA RM L50K30) (Declassified from Confidential, 1/11/55)

The starting of "buzz" is explained as being caused by a separation on the inner surface of the cowling produced by a velocity discontinuity across a vortex sheet arising from a shock intersection. The explanation has been confirmed by tests of a number of inlet designs, and it has been shown that a useful range of stable flow regulation is attainable. Values of minimum stable entering volume flow for configurations of practical interest are presented for a range of Mach number from 1.90 to 2.70.

NACA RM L53E06a

SOME NOTES ON THE AERODYNAMIC LOADS ASSOCIATED WITH EXTERNAL-STORE INSTALLATIONS. H. Norman Silvers and Thomas C. O'Bryan. June 1953. 17p. diagrs. (NACA RM L53E06a) (Declassified from Confidential, 12/10/54)

The results of recent investigations of the aerodynamic loads associated with external stores are considered with a view toward indicating certain observations that may prove helpful in the design of future external store installations. Consideration was given to store-induced wing loads and to direct external store loads.

NACA RM L53G07

WIND-TUNNEL INVESTIGATION OF THE BEHAVIOR OF PARACHUTES IN CLOSE PROXIMITY TO ONE ANOTHER. Stanley H. Scher. August 1953. 12p. photos. (NACA RM L53G07) (Declassified from Confidential, 1/11/55)

An investigation made with small tethered parachutes in the Langley 20-foot free-spinning tunnel indicated that parachutes side by side had little effect on one another, but that when one parachute got into the wake above another parachute, the upper parachute sometimes collapsed on top of the lower parachute.

CURRENT NACA REPORTS

NACA Rept. 1165

UNSTEADY OBLIQUE INTERACTION OF A SHOCK WAVE WITH A PLANE DISTURBANCE. Franklin K. Moore. 1954. ii, 21p. diagrs. (NACA Rept. 1165. Formerly TN 2879)

Analysis is made of the flow field produced by oblique impingement of weak plane disturbances of arbitrary profile on a plane normal shock. Three types of disturbance are considered: (a) Sound wave propagating in the gas at rest into which the shock moves. The sound wave refracts either as a simple isentropic sound wave or an attenuating isentropic pressure wave, depending on the angle between the shock and the incident sound wave. A stationary vorticity wave of constant pressure appears behind the shock. (b) Sound wave overtaking the shock from behind. The sound wave reflects as a sound wave, and a stationary vorticity wave is produced. (c) An incompressible vorticity wave stationary in the gas ahead of the shock. The incident wave refracts as a stationary vorticity wave, and either a sound wave or attenuating pressure wave is also produced. Computations are presented for the first two types of incident wave, over the range of incidence angles, for shock Mach numbers of 1, 1.5, and ∞.

NACA Rept. 1167

METHOD FOR CALCULATING THE ROLLING AND YAWING MOMENTS DUE TO ROLLING FOR UNSWEPT WINGS WITH OR WITHOUT FLAPS OR AILERONS BY USE OF NONLINEAR SECTION LIFT DATA. Albert P. Martina. 1954. ii, 16p. diagrs., 11 tabs. (NACA Rept. 1167. Formerly TN 2937)

The methods of NACA Reports 865 and 1090 have been applied to the calculation of the rolling- and yawing-moment coefficients due to rolling for unswept wings with or without flaps or ailerons. The methods allow the use of nonlinear section lift data together with lifting-line theory. Two calculated examples are presented in simplified computing forms in order to illustrate the procedures involved.

NACA Rept. 1168

SECONDARY FLOWS AND BOUNDARY-LAYER ACCUMULATIONS IN TURBINE NOZZLES. Harold E. Rohlik, Milton G. Kofskey, Hubert W. Allen and Howard Z. Herzig. 1954. ii, 32p. diagrs., photos., 3 tabs. (NACA Rept. 1168. Formerly TN 2871; TN 2909; TN 2989)

The results of detailed measurements of the high-speed flows in three turbine nozzle configurations are interpreted, with the aid of low-speed flow-visualization experiments, in order to establish the sources and patterns of the secondary flows there. The secondary-flow mechanism causes local accumulation of high-loss material by transporting boundary-layer fluids across the channels on the walls, as well as radially in the blade wakes and boundary layers. The size and location of these boundary-layer accumulations depend largely on the blade velocity profiles, not on the radial distribution of circulation along the blades.

NACA Rept. 1170

BEHAVIOR OF MATERIALS UNDER CONDITIONS OF THERMAL STRESS. S. S. Manson. 1954. ii, 34p. diagrs., photos., 6 tabs. (NACA Rept. 1170. Formerly TN 2933)

A review is presented of available information on the behavior of brittle and ductile materials under conditions of thermal stress and thermal shock. For brittle materials, simple formulas relating physical properties to thermal-shock resistance are derived and used to determine the relative significance of two indices currently in use for rating materials. The importance of simulating operating conditions in thermal-shock testing is deduced from the formula and is experimentally illustrated by showing that BeO could be both inferior or superior to Al_2O_3 in thermal shock depending on the testing conditions. For ductile materials, thermal-shock resistance depends upon the complex interrelation among several metallurgical variables which seriously affect strength and ductility. These variables are briefly discussed and illustrated from literature sources. The importance of simulating operating conditions in tests for rating ductile materials is especially to be emphasized because of the importance of testing conditions in metallurgy. A number of practical methods that have been used to minimize the deleterious effects of thermal stress and thermal shock are outlined.

NACA TN 3347

A WIND-TUNNEL TEST TECHNIQUE FOR MEASURING THE DYNAMIC ROTARY STABILITY DERIVATIVES INCLUDING THE CROSS DERIVATIVES AT HIGH MACH NUMBERS. Benjamin H. Beam. January 1955. 35p. diagrs., photos. (NACA TN 3347)

An experimental technique for measuring dynamic stability derivatives of a model airplane in a wind tunnel is described. A single-degree-of-freedom, feedback-controlled, forced-oscillation system was used to measure the stability derivatives which are important in estimating the lateral and longitudinal oscillatory motions of a rigid airplane. Some representative experimental data are included.

NACA TN 3350

THE LINEARIZED EQUATIONS OF MOTION UNDERLYING THE DYNAMIC STABILITY OF AIRCRAFT, SPINNING PROJECTILES, AND SYMMETRICAL MISSILES. A. C. Charters. January 1955. 102p. diagrs. (NACA TN 3350)

Linearized equations of motion are derived for aircraft with mirror symmetry and for spinning projectiles with both rotational and mirror symmetry. The customary set of dynamic stability derivatives is extended to include the aerodynamic effects of spin. The aircraft and projectile cases are treated alike and the consequences of symmetry and spin are shown by a comparison of the equations for the two cases. Dynamic stability conditions are derived. The equations for spinning projectiles are applied to the analysis of flight test data from the aerodynamics range.

NACA TN 3358

GUST-LOAD AND AIRSPEED DATA FROM ONE TYPE OF FOUR-ENGINE AIRPLANE ON FIVE ROUTES FROM 1947 TO 1954. Walter G. Walker. January 1955. 28p. diagrs., 4 tabs. (NACA TN 3358)

This paper presents the results of an analysis of approximately 100,000 hours of V-G data from one type of four-engine civil transport airplane to determine the magnitude and frequency of occurrence of the gust loads and gusts. The normal accelerations differed by approximately 15 percent and the derived gust velocities by about 18 percent for the five operations investigated. The gust loads of the present operations were less than the loads experienced by other four-engine civil transports previously investigated, but the differences are not significant. The present data indicated only small differences due to seasonal effects and different operational utilization.

NACA TN 3363

LOW-SPEED WIND-TUNNEL INVESTIGATION OF A TRIANGULAR SWEPTBACK AIR INLET IN THE ROOT OF A 45° SWEPTBACK WING. Arvid L. Keith, Jr. and Jack Schiff. January 1955. 65p. diagrs., photos., 5 tabs. (NACA TN 3363. Formerly RM L50I01)

Results of a low-speed study of a 45° sweptback wing-root air-inlet configuration believed suitable for transonic-speed airplanes are presented. The inlet-configuration lift and drag characteristics are compared with those of a basic model. Boundary-layer growth along the fuselage nose, inlet total-pressure recoveries, and static-pressure distributions over the inlet and wing surfaces are presented for wide ranges of inlet-velocity ratio and angle of attack.

NACA TN 3386

SOME CONSIDERATIONS ON TWO-DIMENSIONAL THIN AIRFOILS DEFORMING IN SUPERSONIC FLOW. Eugene Migotsky. January 1955. 36p. diagrs. (NACA TN 3386)

The aerodynamic characteristics of indicially cambered two-dimensional airfoils in supersonic flow are determined theoretically. The power required to sustain a general time-varying chordwise deformation is determined. Stability boundaries are presented for the harmonically oscillating parabolic mode. The thickness distribution of a beam having a parabolic fundamental bending mode, in vacuo, is determined.

NACA TN 3388

A FIBROUS-GLASS COMPACT AS A PERMEABLE MATERIAL FOR BOUNDARY-LAYER-CONTROL APPLICATIONS USING AREA SUCTION. Robert E. Dannenberg, James A. Weiberg and Bruno J. Gambucci. January 1955. 20p. diagrs., photos., 2 tabs. (NACA TN 3388)

The resistance to air flow of fibrous-glass compacts suitable for boundary-layer control was measured. The flow resistance is related to the thickness and density of the fibrous-glass compacts. Constant thickness compacts with specified permeability distributions were fabricated and tested.

Aeronautical Research Council (Gt.Brit.)
A SURVEY OF SCALE EFFECTS ON THE HYDRODYNAMIC TESTING OF SEAPLANE MODELS. R. Parker. 1954. 29p. diagrs., photos., tab. (ARC CP 179)

A general survey is made of all the factors where true dynamic similarity cannot be achieved in model tests of seaplane hulls, and the likely effects on test results are discussed with reference to towing tank models and medium size research aircraft. In resistance tests the correction for Reynolds number effects requires more investigation. Pressure effects are likely to affect the breakaway of flow at small discontinuities such as extreme fairings with resultant errors in both stability and resistance test results. More accurate and systematic full scale data than at present is available is needed before methods of allowing for this can be satisfactorily developed.

OPTICAL CONSIDERATIONS AND LIMITATIONS OF THE SCHLIEREN METHOD. G. S. Speak and D. J. Walters. 1954. 25p. diagrs., 6 tabs. (ARC R & M 2859; 13,066. Formerly RAE Tech. Note IAP 968)

The elementary principles of the schlieren method are described, with reference to an ideal basic system. The experimental procedure in setting up the system is covered from the same aspect. It is concluded that the schlieren method may be used qualitatively at extremely high sensitivities with satisfactory results, but is not suitable for quantitative work where small pressure or density changes are involved. A secondary conclusion is that the twin-mirror system is in general the best for overall ease of interpretation of results, though local considerations may modify this choice.

FIFTY YEARS OF BOUNDARY LAYER THEORY AND EXPERIMENT. Hugh L. Dryden. (Presented at meeting of Fluid Dynamics Div., Amer. Physical Soc., Hotel Chamberlin, Old Point Comfort, Va., Nov. 23, 1954). 17p.

This paper summarizes boundary-layer theory and experiment since Prandtl's boundary-layer theory was presented 50 years ago. It tells the story of the development of the new concept, its slow acceptance and growth, and its spread from group to group within the country of origin and its diffusion to other countries of the world.

THE S. N. E. C. M. A. TRANSONIC WIND TUNNEL. (La Soufflerie Transsonique de la S. N. E. C. M. A.). O. Frenzl. November 1954. 30p. diagrs., photos. (Trans. from Docaero, no.23, Sept., 1953, p. 1-18)

The new S. N. E. C. M. A. wind tunnel is operated by a vapor ejector. After a discussion of its principle, the report describes the air reheater with gravel designed to prevent condensation, the antiturbulence grid, the test section with semiguided jet of 400 x 600 rectangular cross section, of 2.70 m in length, the control valves, the ejector, the diffuser, and the steam accumulator. The three-component wind-tunnel balance with six pressure cells, the schlieren apparatus, the Mach meter, and multiple pressure gage are briefly discussed, and the more particularly satisfactory results of the first tests are reported.

Cornell University, Graduate School of Aeronautical Engineering. ON THE GROWTH OF PLASTIC DEFORMATION IN A BAR SUBMITTED TO LONGITUDINAL IMPACT. C. Riparbelli. January 1953. 41p. diagrs. (Cornell University, Graduate School of Aeronautical Engineering)

The deformation of a semi-infinite bar submitted to end impact is computed step-by-step, each step corresponding to one element of a bar and to one time interval. At every step, two phases are considered: (a) propagation of the deformation wave as if it were elastic, (b) increment of deformation due to creep.

N-35237*

Cornell University, Graduate School of Aeronautical Engineering. DISTRIBUTION OF STRESS, STRAIN, VELOCITY IN A BAR OF NON-UNIFORM CROSS-SECTION UNDERGOING LONGITUDINAL IMPACT IN THE PLASTIC RANGE. Carlo Riparbelli. May 15, 1954. 77p. diagrs., photos. (Cornell University, Graduate School of Aeronautical Engineering)

A method for computing the distribution of stress, strain, and velocity in a bar of nonuniform cross section in the plastic domain is offered. This is based on the separate computation of two simultaneous phenomena, namely, propagation of elastic strain component, taking into account the taper effect, and plastic flow. The computation is performed step-by-step and the above said two phases are considered at each step. The distribution of plastic strain is thus predicted under the assumption of its being irreversible. Comparison is offered with distributions of plastic strain from experiments on copper bars of nonuniform cross section.

CURRENT NACA REPORTS

NACA Rept. 1156

EXPERIMENTS TO DETERMINE NEIGHBORHOOD REACTIONS TO LIGHT AIRPLANES WITH AND WITHOUT EXTERNAL NOISE REDUCTION. Fred S. Elwell, Aeronautical Research Foundation. 1953. ii, 43p. diagrs., photos., 12 tabs. (NACA Rept. 1156. Formerly TN 2728)

Experiments to determine neighborhood reactions to the noise of light airplanes with and without noise-reduction equipment were conducted at a number of sites which might be convenient locations for landing strips within the metropolitan area of Boston, Mass. Two standard airplanes and two airplanes modified by reduction gears, four-bladed propellers, and engine exhaust silencers were used. Flights were made close to residential properties of varying income levels, population densities, and proximity to trade centers in order to determine whether the degree of noise reduction previously found to be aerodynamically and structurally practicable produced a significant reduction in neighborhood objections to such aircraft operations.

NACA Rept. 1157

ANALYTICAL DERIVATION AND EXPERIMENTAL EVALUATION OF SHORT-BEARING APPROXIMATION FOR FULL JOURNAL BEARINGS. George B. DuBois and Fred W. Ocvirk, Cornell Univ. 1953. ii, 32p. diagrs., photos., 4 tabs. (NACA Rept. 1157. Formerly TN 2808; TN 2809)

An approximate analytical solution including the effect of end leakage from the oil film of short plain bearings is presented because of the importance of endwise flow in sleeve bearings of the short lengths commonly used. The analytical approximation is supported by experimental data and includes the endwise flow and that part of the circumferential flow which is related to surface velocity and film thickness. Methods are also discussed for approximating a maximum bearing temperature for pressure-lubricated bearings and for evaluating the effect of deflection in misalinement on the eccentricity ratio at the ends of a bearing.

NACA Rept. 1166

RELATION BETWEEN ROUGHNESS OF INTERFACE AND ADHERENCE OF PORCELAIN ENAMEL TO STEEL. J. C. Richmond, D. G. Moore, H. B. Kirkpatrick and W. N. Harrison, National Bureau of Standards. 1954. ii, 9p. diagrs., photos., 7 tabs. (NACA Rept. 1166. Formerly TN 2934)

The relationship between adherence and roughness of interface between enamel and iron was studied. Porcelain-enamel ground coats were prepared and applied under conditions that gave various degrees of adherence. The variations were produced by (a) varying the amount of cobalt-oxide addition in the frit; (b) varying the type of metallic-oxide addition in the frit, keeping the amount constant at 0.8 weight percent; (c) varying the surface treatment of the metal before application of the enamel, by pickling, sandblasting, and polishing; and (d) varying the time of firing of the enamel containing 0.8 percent of cobalt oxide. A positive correlation was found between adherence and roughness of the interface.

NACA Rept. 1180

THEORETICAL STUDY OF THE TRANSONIC LIFT OF A DOUBLE-WEDGE PROFILE WITH DETACHED BOW WAVE. Walter G. Vincenti and Cleo B. Wagoner. (Portions of this work were reported at the eighth International Congress on Theoretical and Applied Mechanics, Istanbul, Turkey, August 20-28, 1952). 1954. ii, 24p. diagrs., 2 tabs. (NACA Rept. 1180. Formerly TN 2832)

Numerical calculations are described of the aerodynamic characteristics at small angle of attack of a thin, doubly symmetrical, double-wedge profile in the range of supersonic flight speed in which the bow wave is detached. The analysis is carried out within the framework of the transonic (nonlinear) small-disturbance theory. The following results are provided as functions of the transonic similarity parameter: (1) chordwise lift distribution, (2) lift-curve slope, and (3) position of center of lift.

NACA RM E53E29

IGNITION-DELAY DETERMINATIONS OF FURFURYL ALCOHOL AND MIXED BUTYL MERCAPTANS WITH VARIOUS WHITE FUMING NITRIC ACIDS USING MODIFIED OPEN-CUP AND SMALL-SCALE ROCKET ENGINE APPARATUS. Dezso J. Ladanyi, Riley O. Miller and Glen Hennings. February 1955. 17p. diagrs., photos., 4 tabs. (NACA RM E53E29)

Approximate linear relations were obtained when the logarithm of ignition delay was plotted against the reciprocal of absolute temperature for furfuryl alcohol and white fuming nitric acid (16 percent water) in the small-scale rocket engine (approximately 50 lb thrust) and for mixed butyl mercaptans and white fuming nitric acid (2 percent water) in the modified open-cup apparatus. Zero-temperature coefficients of ignition delay were obtained for furfuryl alcohol and white fuming nitric acid (2 percent water) in both apparatus for the temperature ranges investigated.

NACA RM E54K10

SOME MEASUREMENTS OF BOILING BURN-OUT. Warren H. Lowdermilk and Walter F. Weiland. February 1955. 18p. diagrs., photo., 3 tabs. (NACA RM E54K10)

Measurements of boiling burnout heat flux for water flowing upward through an electrically heated tube were obtained for ranges of velocity from 0.1 to 19 feet per second; pressure from atmosphere to 2000 pounds per square inch; length-diameter ratios of 25, 37.5, and 50; and inlet subcooling from zero to 400° F. Unsteady flow was obtained for burnout conditions with a restriction located downstream of the point of burnout. A compressible fluid plenum chamber located between the restriction and the exit of the test section resulted in steady-flow burnout with a tenfold increase in the burnout heat flux.

NACA RM E54L10

MEASURED EFFECTIVE THERMAL CONDUCTIVITY OF URANIUM OXIDE POWDER IN VARIOUS GASES AND GAS MIXTURES. J. S. Boegli and R. G. Deissler. March 1955. 20p. diagrs., tab. (NACA RM E54L10)

This study was undertaken as part of a series of investigations to determine the effective conductivity of UO_2 powder with a density of 59.5 percent of the density of the solid UO_2 at temperatures between 200° and 1500° F. Experimental effective conductivities of the gas-powder mixtures were determined for helium, argon, and nitrogen gases, and mixtures of helium-argon and xenon-krypton gases. All tests were performed at a gas pressure above the breakaway pressure, where the thermal conductivity is independent of pressure. A method for determination of the relative thermal conductivity of the solid was devised from knowledge of the effective conductivity of the powder and the conductivity of the gases used in the two-phase system. This method was applied to the UO_2 used in this investigation.

NACA TM 1340

LIFT ON A BENT, FLAT PLATE. (Auftrieb einer geknickten ebenen Platte). F. Keune. February 1955. 15p. diagrs. (NACA TM 1340. Trans. from Bericht der Aerodynamischer Versuchsanstalt Göttingen. Luftfahrtforschung, Mar. 20, 1936, Annual Volume, p. 85-87)

The lift on a bent, flat plate is calculated exactly by the use of conformal mapping. Results are presented in terms permitting direct determination of the angle of zero lift, the lift coefficient, and the lift-curve slope for any flap-chord ratio, flap-deflection angle, and angle of attack.

NACA TM 1370

SOME MEASUREMENTS OF TIME AND SPACE CORRELATION IN WIND TUNNEL. (Quelques Mesures de Corrélation Dans le Temps et L'Espace en Soufflerie). A. Favre, J. Gaviglio and R. Dumas. February 1955. 21p. diagrs. (NACA TM 1370. Trans. from La Recherche Aéronautique, no. 32, Mar.-Apr., 1953, p. 21-28).

Results are presented of research obtained by means of an apparatus for measurement of time and space correlation and of a spectral analyser in the study of the longitudinal component of turbulence velocities in a wind tunnel downstream of a grid of meshes. Application to the case of a flat-plate boundary layer is illustrated. These researches were made at the Laboratoire de Mécanique de l'Atmosphère de l'I. M. F. M. for the O. N. E. R. A.

NACA TN 3281

INTERGRANULAR CORROSION OF HIGH-PURITY ALUMINUM IN HYDROCHLORIC ACID. I - EFFECTS OF HEAT TREATMENT, IRON CONTENT, AND ACID COMPOSITION. M. Metzger and J. Intrater, Columbia University. February 1955. 38p. photos., 8 tabs. (NACA TN 3281)

The intergranular corrosion of high-purity aluminum in hydrochloric acid was studied as a function of iron content, heat treatment, and acid composition under conditions where the rate of intergranular penetration was of the order of 1 millimeter per week. The behavior of specimens quenched to retain a single-phase structure indicated the rate of attack on the high-angle grain boundaries to be influenced by the segregation in these boundaries of iron and possibly other impurity atoms.

NACA TN 3322

AN ACCURATE AND RAPID METHOD FOR THE DESIGN OF SUPERSONIC NOZZLES. Ivan E. Beckwith and John A. Moore. February 1955. 57p. diagrs., 3 tabs. (NACA TN 3322)

A procedure is given for designing two-dimensional nozzles in which the streamline coordinates are computed directly from tabulated flow parameters and appropriate equations. The method of characteristics was used to obtain the first part of the flow which consists of a continuous expansion from a uniform sonic flow to a radial flow. The Foelsch equations are used for the transition from this radial flow to the final uniform flow. Information is presented which enables the designer to select and compute rapidly the wall contour for any nozzle or series of nozzles for a wide range of length-to-height ratio, Mach number, and wall angle at the inflection point.

NACA TN 3325

SIMILAR SOLUTIONS FOR THE COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH HEAT TRANSFER AND PRESSURE GRADIENT. Clarence B. Cohen and Eli Reshotko. February 1955. 67p. diagrs., 2 tabs. (NACA TN 3325)

Stewartson's equations for the compressible laminar boundary layer with pressure gradient and heat transfer are solved for pressure gradients varying from that causing separation to the infinitely favorable gradient and for wall temperatures from absolute zero to twice the free-stream stagnation temperature. For the case of favorable pressure gradients with heated walls, it is shown that the velocity within a portion of the boundary layer must exceed the local external velocity. The variation of a Reynolds analogy parameter, which indicates the ratio of skin friction to heat transfer, is from zero to 7.4 for a surface of temperature twice the free-stream stagnation temperature and from zero to 2.8 for a surface held at absolute zero, where the value 2 applies to a flat plate.

NACA TN 3330

INGESTION OF FOREIGN OBJECTS INTO TURBINE ENGINES BY VORTICES. Lewis A. Rodert and Floyd B. Garrett. February 1955. 23p. diagrs., photos. (NACA TN 3330)

The ingestion of foreign objects by vortices formed between engine inlet and ground surface was investigated with a 5000-pound-thrust axial-flow jet engine. Pebbles, typical of objects that damage jet engines, were projected into the air by the vortices and were drawn into the engine by the high-velocity inlet-air stream. Vortex formation depended on engine speed, engine height, and surface wind. Pebbles lodged in surface cracks were more readily picked up than those exposed on a smooth surface. A motion-picture supplement may be obtained on loan from NACA Headquarters, Washington, D. C.

NACA TN 3339

EXPERIMENTS ON TURBULENT FLOW THROUGH CHANNELS HAVING POROUS ROUGH SURFACES WITH OR WITHOUT AIR INJECTION. E. R. G. Eckert, Anthony J. Diaguila and Patrick L. Donoughe. February 1955. 45p. diagrs., photos., tab. (NACA TN 3339)

Experiments were conducted to study the flow characteristics along porous rough surfaces with and without air injection for turbulent flow in a channel. Four degrees of roughness were studied with ratios of air-injection velocity to mainstream velocity from 0 to approximately 0.017. Velocity distributions along the rough porous surfaces and friction coefficients are presented.

NACA TN 3340

GENERALIZATION OF GAS-FLOW-INTERFEROMETRY THEORY AND INTERFEROGRAM EVALUATION EQUATIONS FOR ONE-DIMENSIONAL DENSITY FIELDS. Walton L. Howes and Donald R. Buchele. February 1955. 70p. diagrs., photos. (NACA TN 3340)

Generalized equations concerned with gas-flow interferometry are applied in developing interferogram evaluation equations for one-dimensional density fields. Theoretical limitations and systematic errors of the equations are investigated. Criteria for applicability and for avoiding apparent-ray-trace crossing are presented. The theory indicates that errors caused by an extended light source and test-section windows are negligible in practice. Analytical and experimental checks of the validity of the evaluation equations are presented. Theoretical results are compared with those of previous analyses.

NACA TN 3352

EXPERIMENTAL INVESTIGATION OF MISALINING COUPLES AND ECCENTRICITY AT ENDS OF MISALINED PLAIN BEARINGS. G. B. DuBois, F. W. Ocvirk and R. L. Wehe, Cornell University. February 1955. 81p. diagrs., photo., 3 tabs. (NACA TN 3352)

An experimental investigation was conducted to study the behavior of full journal bearings under steady load when acted on by a steady misalining couple. Displacements of the ends of the journal axis were measured with either an axial couple applied in the plane of the central load or a twisting couple in the plane normal to the central load. Oil-flow-rate and bearing-temperature measurements were also made to determine the effect of misalining couples on these quantities.

NACA TN 3355

PRELIMINARY INVESTIGATION OF A STICK SHAKER AS A LIFT-MARGIN INDICATOR. James P. Trant, Jr. February 1955. 19p. diagrs., photos. (NACA TN 3355)

Preliminary tests with simulator equipment were made to determine the ability of subjects to use frequency or amplitude of vibration of the pilot's control stick, or both, as an indicator for maintaining a desired lift margin below the stall. The results showed that the desired lift margin could probably be maintained, provided the allowable variation from the desired angle of attack or lift coefficient produced either changes in amplitude of vibration of about 100 percent or changes in frequency of 40 percent, or both.

NACA TN 3368

ANALYSIS OF BEHAVIOR OF SIMPLY SUPPORTED FLAT PLATES COMPRESSED BEYOND THE BUCKLING LOAD INTO THE PLASTIC RANGE. J. Mayers and Bernard Budiansky. February 1955. 44p. diagrs. (NACA TN 3368)

An analysis is presented of the postbuckling behavior of a simply supported square flat plate with straight edges compressed beyond the buckling load into the plastic range. The method of analysis involves the application of a variational principle of the deformation theory of plasticity in conjunction with computations carried out on a high-speed calculating machine. Numerical results are obtained for several plate proportions and for one material. The results indicate plate strengths greater than those that have been found experimentally on plates that do not satisfy straight-edge conditions.

NACA TN 3369

MINIMUM-DRAG BODIES OF REVOLUTION IN A NONUNIFORM SUPERSONIC FLOW FIELD. Conrad Rennemann, Jr. February 1955. 25p. diagrs. (NACA TN 3369)

A general expression for the cross-sectional-area distribution of the minimum-drag body of revolution of given volume and length in a nonuniform supersonic flow field is derived on the basis of linearized theory. This result is applied to the determination of the minimum-drag body of revolution of given volume and length located in the flow field of a parabolic body of revolution. The interference pressures from a main body acting on a satellite body have a negligible effect on the shape for minimum wave drag of the satellite body.

NACA TN 3371

ANALYSIS OF ACCELERATIONS, GUST VELOCITIES, AND AIRSPEEDS FROM OPERATIONS OF A TWIN-ENGINE TRANSPORT AIRPLANE ON A TRANSCONTINENTAL ROUTE FROM 1950 TO 1952. Thomas L. Coleman and Walter G. Walker. February 1955. 16p. diagrs., 3 tabs. (NACA TN 3371)

VGH time-history data obtained from one type of twin-engine transport airplane during operations from 1950 to 1952 on a transcontinental route are analyzed in order to determine the magnitude and frequency of occurrence of gust accelerations, gust velocities, and the associated airspeeds and altitudes. The present results compared favorably with results previously obtained for a similar type of twin-engine airplane during other operations. The present operations indicate a less severe acceleration history than that shown for the other airplane, apparently because of the lower operating airspeed in rough air.

NACA TN 3389

AXIALLY SYMMETRIC SHAPES WITH MINIMUM WAVE DRAG. Max. A. Heaslet and Franklyn B. Fuller. February 1955. 46p. diagrs. (NACA TN 3389)

Optimum bodies consisting of a basic cylinder with added peripheral volume are derived and presented in terms of the effective radius-length ratio. Variation of this parameter from 0 to ∞ encompasses the spectrum of results from slender to two-dimensional. A reciprocal theorem leads to simple interpretations of variational problems.

NACA TN 3396

ICING LIMIT AND WET-SURFACE TEMPERATURE VARIATION FOR TWO AIRFOIL SHAPES UNDER SIMULATED HIGH-SPEED FLIGHT CONDITIONS. Willard D. Coles. February 1955. 33p. diagrs., photos. (NACA TN 3396)

The variation of wet-surface temperature and the conditions that will result in ice-free surfaces for high-speed flight through clouds were investigated experimentally. The results are compared with calculated values obtained with an analytical method. The analytical results were generally conservative, giving wet-surface temperatures 2° to 4° F lower than the experiments and predicting the formation of ice at values of ambient-air temperature up to 12° F higher than the experiments. The location of analytically determined critical regions on the bodies for the initial formation of ice was experimentally substantiated.

NACA TN 3397

AN EVALUATION OF NON-NEWTONIAN FLOW IN PIPE LINES. Ruth N. Weltmann. February 1955. 40p. diagrs., tab. (NACA TN 3397)

An analysis is presented of a method for determining pressure losses due to the flow of non-Newtonian materials in pipe lines by using basic flow data obtained from measurements of flow curves, which are rate-of-shear - shearing-stress curves. The advantages of properly designed rotational viscometers over capillary viscometers for measuring these flow curves and interpreting them to obtain the basic flow parameters are discussed. Dimensionless parameters are calculated from these basic flow data and are used to construct a generalized friction diagram to describe the flow characteristics of Newtonian and non-Newtonian materials in pipe lines.

NACA TN 3398

A THERMAL EQUATION FOR FLAME QUENCHING. A. E. Potter, Jr. and A. L. Berlad. February 1955. 18p. diagrs., tab. (NACA TN 3398)

A thermal quenching equation is derived; the equation is essentially an extension of a previously proposed diffusional concept. By proper choice of the rate-controlling chemical reaction, the equation becomes suitable for use with rich as well as lean fuel-air mixtures. The equation was tested, using published quenching-distance data for propane-oxygen-nitrogen flames, which include the effect of oxygen-nitrogen ratio, equivalence ratio, pressure, and initial temperature.

NACA TN 3402

BOUNDARY LUBRICATION OF STEEL WITH FLUORINE- AND CHLORINE-SUBSTITUTED METHANE AND ETHANE GASES. S. F. Murray, Robert L. Johnson and Max A. Swikert. February 1955. 17p. photos., diagrs., 2 tabs. (NACA TN 3402)

Sliding-friction experiments were made with steel surfaces in atmospheres of halogenated gases. Under the conditions of this investigation, the most stable or fully fluorinated gases gave no surface protection. Several fluorinated compounds containing two or more chlorine atoms per molecule served as effective boundary lubricants (reduced friction and prevented excessive wear, surface welding, and metal transfer) in a manner comparable with a conventional liquid lubricant. Run-in procedure, bearing materials, and moisture availability appear to be critical in boundary lubrication by gaseous materials.

NACA TN 3405

TEMPERATURE-COMPOSITION LIMITS OF SPONTANEOUS EXPLOSION FOR NINE ALKYLSILANES WITH AIR AT ATMOSPHERIC PRESSURE. Rose L. Schalla and Glen E. McDonald. February 1955. 13p. diagrs. (NACA TN 3405)

To provide safe-handling information, the spontaneous explosion limits of nine alkylsilanes were determined as a function of temperature and fuel-air composition at a pressure of 1 atmosphere. Over a fuel concentration range of about 2 to 9 percent by volume, the fuels studied were nonexplosive below the following temperatures: tetramethylsilane $(CH_3)_4Si$, 450° C; trimethylsilane $(CH_3)_3SiH$, 300° C; diethylsilane $(C_2H_5)_2SiH_2$, 255° C; dimethylsilane $(CH_3)_2SiH_2$, 220° C; ethylsilane $(C_2H_5)SiH_3$, 215° C; isobutylsilane $(i\text{-}C_4H_9)SiH_3$, 200° C; n-butylsilane $(n\text{-}C_4H_9)SiH_3$, 185° C; methylsilane $(CH_3)SiH_3$, 125° C; and vinylsilane $H_2C = CH\text{-}SiH_3$, 90° C.

NACA TN 3409

CHAIN BREAKING AND BRANCHING IN THE ACTIVE-PARTICLE DIFFUSION CONCEPT OF QUENCHING. Frank E. Belles and A. L. Berlad. February 1955. 37p. diagrs., 3 tabs. (NACA TN 3409)

General quenching-distance equations that take into account gas-phase chain breaking and branching and

the effect of the wall efficiency for destruction of active particles are derived as extensions of the original simple theory of quenching by diffusion of active particles. The general characteristics of the equations are discussed. Quenching distance data from the literature for propane-oxygen-nitrogen mixtures are treated in a consistent manner. The effects of elevated initial mixture temperature are predicted and agree qualitatively with observed trends. It is found that the simple theory correlates all the data satisfactorily.

Royal Aircraft Establishment (Gt. Brit.)
METHODS OF DETERMINATION AND OF FIXING BOUNDARY LAYER TRANSITION ON WIND TUNNEL MODELS AT SUPERSONIC SPEEDS. K. G. Winter, J. B. Scott-Wilson and F. V. Davies. September 1954. 27p. diagrs., photos. (RAE Tech. Note Aero 2341)

An account is given of methods used in supersonic wind tunnels for observation of boundary-layer phenomena, in particular of the sublimation and oil film techniques. Examples are given of the uses of these techniques. On the fixing of transition, a rough guide is given for the minimum size of wire required, with an example of the use of wires. The results of a brief experiment on the profile of an artificially promoted turbulent boundary layer are given.

SOME NOTES ON A PROPOSAL TO USE A BLOWER TUNNEL FOR VISION IN RAIN TESTS ON AIRCRAFT WINDSCREENS. F. J. Bigg. September 1954. 16p. diagrs., 2 tabs. (RAE Tech. Note Mech. Eng. 187)

For research work on vision through aircraft windscreens in rain, it has been suggested many times that ground tests should be made using a blower tunnel with simulated rain. This note describes some tests and calculations, which have recently been made, from which it has become apparent that it is not possible to produce realistic rain conditions by this method. The possibility of using a large vertical wind tunnel has also been considered theoretically and it is concluded that this would also be impracticable.

Royal Aircraft Establishment (Gt. Brit.)
DEVELOPMENT OF AN AIR MASS-FLOW RATE METER. W. J. G. Cox. October 1954. 47p. diagrs., photos. (RAE Tech. Note Instn. 142)

The development of an air mass flow rate meter to cover a very wide range is described which, essentially an analogue computer, gives a two-sweep pointer direct presentation of air mass flow rate, independent of pressure, temperature, and velocity changes within the range of the instrument. The pointers are driven by a servo system which is error-actuated from the computing bridge network, secondary feedback being employed to maintain stability with a saturated angular output rate of approximately 33° per second. Specifications and performance figures are given for the individual transducer elements and the complete instrument, error estimations are made, and the servo stability is discussed.

Royal Aircraft Establishment (Gt. Brit.)
THEORETICAL LOAD DISTRIBUTIONS ON FIN-BODY-TAILPLANE ARRANGEMENTS IN A SIDE-WIND. J. Weber and A. C. Hawk. August 1954. 113p. diagrs., 6 tabs. (RAE Aero 2518)

A theory is developed for calculating the distributions of side force and lift on fin-fuselage-tailplane arrangements in a sidewind but with the tailplane set at zero angle of attack. The results can be extended to other arrangements and to compressible subcritical flow and are required for stability and stressing analysis. This paper is a continuation of a report in which the interference between fin and fuselage was considered. The addition of the tailplane brings changes in the load distribution as well as in the overall forces. The main functions needed for representative cases are given in tables and charts. Results for other geometrical arrangements can be obtained by interpolation.

THE INFLUENCE OF ROLLING MOMENTS ON SPIN RECOVERY AS OBSERVED IN MODEL-SPINNING TESTS. D. J. Harper. 1954. 13p. diagrs., tab. (ARC R & M 2831; ARC 13,538. Formerly RAE Aero 2365)

Several aspects of model-spinning test technique have been brought into prominence by full-scale developments. Correlation between model and full-scale recoveries has been poor in some cases, and it appears that full-scale recovery may depend on some other means in addition to the normal use of rudder and elevator. Analysis of data shows the effects of applied rolling moments and of aileron deflections on both spin and recovery to be closely related to the distribution of loading of the aircraft. The ordinary model-test result can be in error due to scale effects on rolling moments. This report collects the available model data on the effects of applied rolling moments, and also includes model data on the use of ailerons to assist recovery.

THEORETICAL SUPERSONIC DRAG OF NON-LIFTING INFINITE-SPAN WINGS SWEPT BEHIND THE MACH LINES. T. Nonweiler. 1954. 22p. diagrs., 3 tabs. (ARC R & M 2795; ARC 13,896. Formerly RAE Tech. Note Aero 2073)

The wing section is assumed to be arbitrary but identical over the entire wing span. The drag is found according to the linear equations of supersonic flow by considering the flow due to a system of superposed source planes. The drag is found to be finite and the effect of the speed of flight independent of the section shape assumed. The variation of drag with the section shape is shown to be proportional to the integral over the chord of the product of the local wing thickness and the value of the excess pressure existing in incompressible flow at the same position. Methods of reducing drag by changing the section shape are considered.

SOLUTION OF AERO-ELASTIC PROBLEMS BY MEANS OF INFLUENCE COEFFICIENTS. D. Williams. November 1954. 12p. diagr. (RAE Structures 169)

It is shown that, on the basis of the data provided by two sets of influence coefficients for a wing (or other surface) - and "elastic" set giving deflections (and hence incidence angles) in terms of applied loads, and an aerodynamic set giving aerodynamic loads in terms of incidence angles - all "static" aeroelastic problems can easily and expeditiously be solved by the use of a digital computer. It is also suggested that the same method of approach may well be used for solving oscillatory aeroelastic problems such as flutter.

A NOTE ON THE COOLING OF TURBINE ROTOR BLADES BY WATER JETS. K. R. F. Kenworthy. October 1954. 6p. (NGTE Memo. M. 227)

Experimental work at N. G. T. E. on "spray" or "jet" cooling is reviewed and a performance estimate given in comparison with air cooling. It is shown that the gains realizable as a result of the higher maximum cycle temperature are much the same in the two cases. The detrimental effects of the water and, in aircraft applications, the weight of water to be carried lead to the conclusion that spray cooling is inferior to air cooling.

THE SLIP BAND EXTRUSION EFFECT IN COLD ROLLED, SUPER PURITY ALUMINUM. C. A. Stubbington and P. J. E. Forsyth. October 1954. 7p. photos. (RAE Tech. Note Met. 205)

It has been found that by cold rolling pure aluminum to a suitable degree, a slip band extrusion effect can be produced by subsequent fatigue stressing. This effect has been shown to be due to local recrystallization producing soft regions along slip striations, and is analogous to the soft regions produced in aluminum -4 percent copper by accelerated overaging under the action of fatigue stresses.

INTRODUCTORY NOTES TO THE PROBLEMS OF AERODYNAMIC HEATING. R. J. Monaghan. October 1954. 19p. diagrs. (RAE Tech. Note Aero 2346)

This note gives a simplified discussion of the aerodynamic heating problems encountered in high-speed flight, illustrates their magnitude, and considers some means of alleviation. Although the temperatures for zero heat transfer between airstream and aircraft increase rapidly with increase of flight speed, some alleviation can be obtained by choosing a surface finish which loses heat freely by radiation. In addition, small thicknesses of external insulation could be extremely effective in protecting the main structure and the amounts of heat which enter the interior of the aircraft need not be excessive.

AN ELECTROLYTIC METHOD FOR THE DIRECT PRODUCTION OF MAGNESIUM LITHIUM ALLOYS FROM LITHIUM CHLORIDE. J. Smolinski, J. C. Hannam and A. L. Leach. October 1954. 19p. diagrs., photos., 9 tabs. (RAE Met. 80)

Magnesium lithium alloys were made directly at high current efficiency by electrolytic deposition of lithium on to a magnesium cathode from a molten 50 $LiCl$/50 KCl or 75 $LiCl$/25 $BaCl_2$ electrolyte at 560° to 630° C. The relation between sodium contamination in electrolyte and product has been determined. By careful selection of cell materials to avoid sodium contamination, alloys ductile in the aged condition could be made directly without need of refining.

A RATE GYRO FOR USE IN AIRCRAFT DYNAMIC RESPONSE WORK. Keith Smith. October 1954. 13p. diagrs., photos. (RAE Tech. Note Aero 2327)

An instrument to measure angular rate under dynamic conditions, used in conjunction with a galvanometer recorder, has been developed from the existing standard instrumentation rate gyro (Type IT 2-1). With a range of ±8° per second, it has considerably improved dynamic response characteristics. Tests on an oscillating table indicate that the response is flat (±2 percent of static value) up to 8 cycles per

second for an amplitude of $\pm 6^{o}$ per second. Tests at a smaller amplitude were impractical but it is suspected that under these conditions the presence of nonlinear dynamic characteristics might cause a less satisfactory response.

GEOMETRICAL ANALYSIS OF SCHLIEREN PHOTOGRAPHS OF THE FLOW IN THE PLANE OF INCIDENCE OF INCLINED CONE-CYLINDERS AT SUPERSONIC SPEEDS. K. G. Winter. November 1954. 15p. diagrs., photo., tab. (RAE Tech. Note Aero 2345)

Measurements have been made of shock wave positions shown on schlieren photographs of the flow past inclined cone-cylinders. The resulting angles and distances have been correlated to give a general method of estimating the positions of the nose shock waves. The method is satisfactory at Mach numbers between 1.4 and 2.0 for cone-cylinders of semiangle less than 15°, at incidences up to 30°, and is of use in the design of models for supersonic wind tunnels.

A GENERAL METHOD (DEPENDING ON THE AID OF A DIGITAL COMPUTER) FOR DERIVING THE STRUCTURAL INFLUENCE COEFFICIENTS OF AEROPLANE WINGS. D. Williams. November 1954. 32p. diagrs., tab. (RAE Structures 168)

A general method (requiring the aid of a digital computer) is described for deriving the influence coefficients of any type of wing, and hence for evaluating its strength and stiffness characteristics. The method allows for shear deflections, and hence implicitly takes account of effects like shear-lag and warping of wing cross-sections. A rapid method accurate enough to serve as a basis for dynamical calculations is first described, and secondly a more rigorous method on which to base final stressing of the structure.

STUDIES OF FLAMES BURNING WITH CHLORINE TRIFLUORIDE. G. Skirrow, R. A. M. Straker and H. G. Wolfhard. September 1954. 19p. diagr., photos., tab. (RAE RPD 22)

Diffusion flames are described in which fuels such as hydrogen, carbon monoxide, carbon disulphide, water, ammonia, hydrocarbons, and organic halides are burnt with chlorine trifluoride. Chemical equilibrium is nearly established in the main reaction zone as in an oxygen diffusion flame but the chlorine trifluoride flames possess several unusual features. Carbon formation is very heavy with hydrocarbon fuels and it may even impair combustion. Radicals such as C_2 and CN have an unusually long lifetime and their presence in a high-temperature region enhances the luminosity of some of the flames. It is suggested that the persistence of these radicals may be due to the very rapid diffusion of hydrogen into the main reaction zone which effectively prevents the penetration of fluorine to the fuel side of the flame.

THE CALCULATION OF THE PRESSURE DISTRIBUTION ON THICK WINGS OF SMALL ASPECT RATIO AT ZERO LIFT IN SUBSONIC FLOW. J. Weber. September 1954. 66p. diagrs., 4 tabs. (RAE Aero 2519)

The method of expressing the velocity increment over airfoils directly in terms of the section ordinates is extended to cover also straight and swept

wings of finite aspect ratio. The wings considered are untapered in plan form but may be tapered in thickness. The section can be of any given shape. Coefficients required in the calculation are tabulated for the center section of straight and sweptback wings of aspect ratios 0.5, 1, 2, and 4. The remaining calculations can be made very quickly. Since wings of very small aspect ratio can be treated also by the method of slender-body theory, the relations between linear theory, slender-body theory, and linearized slender-body theory are discussed.

THE EFFECT OF ASPECT RATIO ON THE CHORDWISE LOAD DISTRIBUTION OF FLAT AND CAMBERED RECTANGULAR WINGS. J. Weber. October 1954. 40p. diagrs., 2 tabs. (RAE Aero 2525)

The report deals with the "first problem" of airfoil theory, that of determining the shape of the airfoil for a given load distribution. The downwash integral over wing and wake, which is involved in this calculation, is reduced to a very simple form which permits a rapid numerical evaluation for wings of rectangular plan form. This method has been used to check the accuracy of the results of various methods of calculation for small aspect ratio plane rectangular wings by inserting the calculated load distributions into the downwash equation and determining the airfoil shape which is then compared with the plane wing, for which the load distribution was calculated.

THE PRESSURE DISTRIBUTION, (ACCORDING TO THE LINEAR THEORY), ON THE GROUND DUE TO A DELTA WING IN STEADY LEVEL SUPERSONIC FLIGHT. G. M. Roper. November 1954. 45p. diagrs. (RAE Tech. Note Aero 2332)

Effects of angle of attack and thickness are calculated separately, and the results are superimposed. Calculations are made for delta wings of single-wedge section and double-wedge section. The results are given in graphic form. The results can only be expected to give a very rough indication of the actual pressure distribution, since the fluid medium is assumed to be homogeneous, and no account is taken of shock waves. More recent work suggests that, in general, the pressures are overestimated. In particular, no significance should be attached to the very high pressures that occur in the very small region immediately behind the Mach wave from the trailing edge.

Ministry of Supply (Gt. Brit.)
EXPERIENCE OF FATIGUE AT WEYBRIDGE. H. H. Gardner. (Part one of final report prepared by Vickers-Armstrong, Ltd., Weybridge). November 1954. 37p. diagrs., photo. (Ministry of Supply. S & TM 10/54)

During 1942-44 a number of fatigue failures occurred on Wellington aircraft in service. The majority of failures occurred in main spar booms on the tension flanges, resulting in all cases in the loss of the aircraft and the complete crew. This report outlines the causes of these failures and describes the steps which were taken to modify the design, together with the experimental evidence which led to the final form of modification adopted. It is decided that the detail design of the joint was responsible for high stress concentrations at the base of the serrations, and the material of the spar tubes due to the method of manufacture contained high initial tension stresses which increased the tension stresses at the serrations to serious proportions.

CURRENT NACA REPORTS

NACA Rept. 1179

A NOTE ON SECONDARY FLOW IN ROTATING RADIAL CHANNELS. James J. Kramer and John D. Stanitz. 1954. ii, 12p. diagrs. (NACA Rept. 1179. Formerly TN 3013)

A general vector differential equation for the vorticity component parallel to a streamline is derived for steady, nonviscous and incompressible flow in a rotating system. This equation is then simplified by restricting it to rotating radial channels and by making further simplifying assumptions. This simplified equation is used to solve for the secondary vorticity, the vorticity component parallel to the streamline, in three special cases involving different streamtube geometries; the results are presented in a series of figures. The secondary vorticity is shown to decrease with decreased absolute angular velocity of the fluid, decreased inlet total-pressure gradient, decreased length of relative flow path, and increased relative velocity.

NACA RM E54D13

A DROP TEST FOR THE EVALUATION OF THE IMPACT STRENGTH OF CERMETS. B. Pinkel, G. C. Deutsch and N. H. Katz. March 1955. 8p. diagrs., photo. (NACA RM E54D13)

The development of brittle high-temperature materials has focused attention on the impact resistance of these materials. This report describes a device for measuring very small values of impact resistance both at norm and elevated temperatures. The device is believed to eliminate extraneous energies, such as the "toss energy" from the impact strength. The method of testing consists of dropping a hammer from increasing heights so that it strikes near the free end of a cantilever beam specimen. The energy of the hammer when the specimen fractures is the impact strength. Representative values of the impact strengths of several high-temperature materials are given.

NACA TM 1382

STEADY PROPERLY-BANKED TURNS OF TURBOJET-PROPELLED AIRPLANES. (La Virata Corretta Stazionaria Degli Aeroplani Azionati da Turboreattori). Angelo Miele. March 1955. 33p. diagrs., tab. (NACA TM 1382. Trans. from Rivista Aeronautica, v.27, no.1, 1951, p.23-35)

The problem of a jet propelled airplane in a steady turn is analyzed for the case of parabolic and non-parabolic aircraft polars. A general solution is obtained and the special cases of maximum banked turn, maximum angular velocity turn and minimum radius turn are then investigated. A brief comparison of the jet and reciprocating propelled airplane is made. Compressibility effects are considered.

NACA TN 3336

REVIEW OF EXPERIMENTAL INVESTIGATIONS OF LIQUID-METAL HEAT TRANSFER. Bernard Lubarsky and Samuel J. Kaufmann. March 1955. 115p. diagrs., tab. (NACA TN 3336)

Experimental data of various investigators of liquid-metal heat-transfer characteristics were reevaluated using as consistent assumptions and methods as possible and then compared with each other and with theoretical results. The reevaluated data for both local fully developed and average Nusselt numbers in the turbulent flow region were found still to have considerable spread, with the bulk of the data being lower than predicted by existing analysis. An equation based on empirical grounds which represents most of the fully developed heat-transfer data is $Nu = 0.625\ Pe^{0.4}$ where Nu represents the Nusselt number and Pe the Peclet number. The theoretical prediction of the heat transfer in the entrance region was found to give lower values, in most cases, than those found in the experimental work.

NACA TN 3338

A DYE-TRACER TECHNIQUE FOR EXPERIMENTALLY OBTAINING IMPINGEMENT CHARACTERISTICS OF ARBITRARY BODIES AND A METHOD FOR DETERMINING DROPLET SIZE DISTRIBUTION. Uwe H. von Glahn, Thomas F. Gelder and William H. Smyers, Jr. March 1955. 73p. diagrs., photos., tab. (NACA TN 3338)

A dye-tracer technique has been developed from which the droplet impingement characteristics of bodies can be determined by colorimetric analysis. The technique is applicable to various wind tunnels provided the humidity of the air stream can be maintained near saturation. A method is also presented whereby the droplet size distribution of the impinging cloud may be determined by relating the experimental impingement characteristics of a body to the theoretical trajectory results for the same body.

NACA TN 3359

AN INVESTIGATION OF DRAINS DISCHARGING LIQUID INTO SUBSONIC AND TRANSONIC STREAMS. Allen R. Vick and Frank V. Silhan. March 1955. 54p. diagrs., photos., tab. (NACA TN 3359)

Results of an investigation on the characteristics of drains discharging liquid into an airstream at Mach numbers from 0.5 to 1.3 are presented in the form of surface stain patterns, schlieren photographs of the flow, and drag measurements for drains of circular, elliptical, and airfoil cross-sectional shapes. Variables whose influence have been investigated include Mach number, liquid reservoir pressure, drain extension, angle of sweep, and end shape. Vent pressure data are presented as differentials between the free-stream and drain static pressure for various tube configurations.

NACA TN 3362

ESTIMATES OF PROBABILITY DISTRIBUTION OF ROOT-MEAN-SQUARE GUST VELOCITY OF ATMOSPHERIC TURBULENCE FROM OPERATIONAL GUST-LOAD DATA BY RANDOM-PROCESS THEORY. Harry Press, May T. Meadows and Ivan Hadlock. March 1955. 48p. diagrs., 4 tabs. (NACA TN 3362)

Relations are derived between the peak gust loads experienced in airplane operations and the probability distribution of root-mean-square gust velocity. These relations are applied in the analysis of operational data on peak gust accelerations to derive estimates of the probability distribution of root-mean-square gust velocity. The application of these results to gust load calculations for other airplane operations is also considered briefly.

NACA TN 3365

AN ANALYSIS OF ACCELERATIONS, AIRSPEEDS, AND GUST VELOCITIES FROM THREE COMMERCIAL OPERATIONS OF ONE TYPE OF MEDIUM-ALTITUDE TRANSPORT AIRPLANE. Thomas L. Coleman, Martin R. Copp, Walter G. Walker and Jerome N. Engel. March 1955. 31p. diagrs., 4 tabs. (NACA TN 3365)

Time-history data obtained by the NACA VGH recorder from one model of a four-engine civil transport airplane during operations on three routes are analyzed to determine the magnitude and frequency of occurrence of gust velocities, gust and maneuver accelerations, and the associated airspeeds. Variations of the gusts and gust accelerations with route and flight condition are indicated. Estimates of the overall gust and gust-load histories for extended operations on one route are obtained by supplementing the data from the NACA VHG recorder with available data from the NACA V-G recorder.

NACA TN 3374

TURBULENT-HEAT-TRANSFER MEASUREMENTS AT A MACH NUMBER OF 2.06. Maurice J. Brevoort and Bernard Rashis. March 1955. 20p. diagrs., tab. (NACA TN 3374)

An axially symmetric annular nozzle was used to obtain essentially flat-plate data on turbulent heat-transfer coefficients and temperature-recovery factors. The test results of this paper are for Mach number 2.06 and for a Reynolds number range of 1.7×10^6 to 8.8×10^7. The heat-transfer-coefficient results are in good agreement with theoretical analyses and the experimental results of the tests of V-2 rockets. The recovery factors are approximately 0.5 percent lower than data for a Mach number of 2.4.

NACA TN 3375

A THEORY FOR PREDICTING THE FLOW OF REAL GASES IN SHOCK TUBES WITH EXPERIMENTAL VERIFICATION. Robert L. Trimpi and Nathaniel B. Cohen. March 1955. 69p. diagrs., photo. (NACA TN 3375)

The nonlinear characteristic differential equations applicable to a quasi-one-dimensional unsteady channel flow with friction and heat transfer are linearized and integrated in functional form for the particular study of small perturbations from ideal shock-tube flows. If the equivalence of unsteady-flow and steady-flow boundary layers is assumed, the theory, evaluated with an equivalent steady-flow turbulent-boundary-layer skin-friction coefficient, predicts that the shock attenuates with distance and that average values of static pressure, velocity, density, and Mach number in the hot gas increase with time at a fixed position, while average sonic speed is simultaneously decreasing with time. Experimental measurements of the shock attenuation with distance and static-pressure variation with time at a fixed position for diaphragm pressure ratios from approximately 4 to 18 gave good agreement with the theoretical predictions.

NACA TN 3377

FLIGHT MEASUREMENTS OF THE VELOCITY DISTRIBUTION AND PERSISTENCE OF THE TRAILING VORTICES OF AN AIRPLANE. Christopher C. Kraft, Jr. March 1955. 32p. diagrs., photos., tab. (NACA TN 3377)

Measurements have been made in flight of the velocity distribution and persistence of the trailing vortices of a propeller-driven fighter-type airplane. The vortices were marked in the atmosphere with smoke and were penetrated by a jet airplane equipped with a high-frequency angle-of-attack vane and a sensitive total-pressure instrument. Photographs of the trailing-vortex filaments were also made.

NACA TN 3380

STUDY OF EFFECTS OF MICROSTRUCTURE AND ANISOTROPY ON FATIGUE OF 24S-T4 ALUMINUM ALLOY. H. A. Lipsitt, G. E. Dieter, G. T. Horne and R. F. Mehl, Carnegie Institute of Technology. March 1955. 41p. diagrs., photos., 4 tabs. (NACA TN 3380)

This report presents the results of an investigation of the statistics of the effects of variation in microstructure (extruded and extruded plus recrystallized) on the fatigue properties of 24S-T4 aluminum alloy notched specimens tested in both the longitudinal and transverse directions.

NACA TN 3390

SECOND-ORDER SUBSONIC AIRFOIL-SECTION THEORY AND ITS PRACTICAL APPLICATION. Milton D. Van Dyke. March 1955. 50p. diagrs., 5 tabs. (NACA TN 3390)

Several recent advances in subsonic compressible flow theory are combined into a unified second-order theory for two-dimensional airfoils. Solutions are given for a number of profiles, and are compared with the results of other theories and of experiment. A straightforward computing scheme is outlined for calculating the pressures on any airfoil at any angle of attack.

NACA TN 3391

FREE-FLIGHT MEASUREMENTS OF TURBULENT-BOUNDARY-LAYER SKIN FRICTION IN THE PRESENCE OF SEVERE AERODYNAMIC HEATING AT MACH NUMBERS FROM 2.8 TO 7.0. Simon C. Sommer and Barbara J. Short. March 1955. 47p. diagrs., photos., 2 tabs. (NACA TN 3391)

Measurements of average skin friction of the turbulent boundary layer have been made in free flight at high rates of heat transfer at high Mach numbers. The results are appreciably higher than zero-heat-transfer wind-tunnel data. The T' method for laminar boundary layers, slightly modified, is shown to agree with results of this and other investigations at widely different Mach numbers and heat-transfer conditions.

NACA TN 3399

A RAPID APPROXIMATE METHOD FOR THE DESIGN OF HUB SHROUD PROFILES OF CENTRIFUGAL IMPELLERS OF GIVEN BLADE SHAPE. Kenneth J. Smith and Joseph T. Hamrick. March 1955. 26p. diagrs., 3 tabs. (NACA TN 3399)

A rapid approximate method for the design of centrifugal compressors of given blade shape with compressible nonviscous flow characteristics has been developed using techniques based upon stream-filament theory. Axial symmetry is assumed, but meridional-plane forces derived from tangential pressure gradients are included. The method was applied to the design of an impeller in order to determine the approximate maximum meridional streamline spacing that could be used. Three numerical solutions for different streamline spacings were made using the same hub profile, blade shape, and prescribed velocity distribution along the hub. The shroud profiles obtained from the three solutions, which utilized 3, 5, and 9 streamtubes, were negligibly different. The approximate computing time required was 15 hours per streamtube.

NACA TN 3400

ANALYSIS OF ERRORS INTRODUCED BY SEVERAL METHODS OF WEIGHTING NONUNIFORM DUCT FLOWS. DeMarquis D. Wyatt. March 1955. 40p. diagrs. (NACA TN 3400)

Three typical duct flow profiles have been numerically analyzed to determine the errors introduced by commonly used averaging methods in the resultant uniform-flow properties. The analysis covers a range of subsonic duct Mach numbers, but is confined to flows having uniform static pressure and total temperature. An averaging method is developed which yields uniform properties that satisfy the integrated mass and momentum of the nonuniform flow. In contrast, it is shown that commonly used averaging methods introduce inherent errors which may markedly affect the validity of duct flow calculations.

NACA TN 3401

LAMINAR BOUNDARY LAYER BEHIND SHOCK ADVANCING INTO STATIONARY FLUID. Harold Mirels. March 1955. 25p. diagrs., 2 tabs. (NACA TN 3401)

A study was made of the laminar compressible boundary layer induced by a shock wave advancing into a stationary fluid bounded by a wall. For weak shock waves, the boundary layer is identical with that which occurs when an infinite wall is impulsively set into uniform motion (Rayleigh problem). A numerical solution was required for strong shocks. Velocity and temperature profiles, recovery factors, and skin-friction and heat-transfer coefficients are tabulated for a wide range of shock strengths.

NACA TN 3403

ANALYTICAL DETERMINATION OF EFFECT OF WATER INJECTION ON POWER OUTPUT OF TURBINE-PROPELLER ENGINE. Albert O. Ross and Merle C. Huppert. March 1955. 29p. diagrs. (NACA TN 3403. Formerly RM E9H17)

An analysis is presented to show the effect of evaporative cooling of the charge air during compression on the performance of a turbine-propeller engine incorporating a centrifugal compressor. Calculations were made with water as the cooling agent for compressor tip speeds of 1200, 1500, and 1800 feet per second. Results indicated that a power augmentation of 200 percent is possible at a compressor tip speed of 1800 feet per second if sufficient water is evaporated during compression to saturate the air at the compressor outlet.

NACA TN 3404

THE COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH FLUID INJECTION. George M. Low. March 1955. 29p. diagrs., 3 tabs. (NACA TN 3404)

A solution of the equations of the compressible laminar boundary layer including the effects of transpiration cooling is presented. The analysis applied to the flow over an isothermal porous plate with a velocity of fluid injection proportional to the reciprocal of the square root of the distance from the leading edge. Several examples are calculated, and the stability of the boundary layer is investigated. It was found that, on a weight-of-coolant basis, transpiration cooling is more effective than other methods considered.

NACA TN 3407

INTERACTION OF A FREE FLAME FRONT WITH A TURBULENCE FIELD. Maurice Tucker. March 1955. 55p. diagrs., 2 tabs. (NACA TN 3407)

Theoretical values are obtained for the root-mean-square flame-generated turbulence velocities and the attenuating pressure fluctuations resulting from a linearized interaction of a constant-pressure combustion front with a field of isotropic turbulence. The anisotropic flame-generated turbulence is found to be of about the same intensity as the incident turbulence. A brief discussion of turbulent flame speed is given. Directly at the flame front the noise pressure levels characterizing the pressure fluctuations are fairly intense (59 to 81 decibels) even at moderate approach-flow turbulence intensities.

NACA TN 3408

ONE-DIMENSIONAL CALCULATION OF FLOW IN A ROTATING PASSAGE WITH EJECTION THROUGH A POROUS WALL. E. R. G. Eckert, John N. B. Livingood and Ernst I. Prasse. March 1955. 29p. diagrs., photo. (NACA TN 3408)

A method is developed for the determination of the local wall permeability necessary to obtain a prescribed local distribution of ejected gas or for the determination of the local distribution of ejected gas resulting from a given local wall permeability. Sample calculations are presented for two blind radial passages of a rotating transpiration-cooled turbine blade. The effects of passage area variation, passage inlet pressure, and passage inlet Mach number are investigated.

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF UNIFORMLY SPACED FLEXIBLE RIBS ON THE STRESSES DUE TO SELF-EQUILIBRATING SYSTEMS APPLIED TO LONG THIN-WALLED CYLINDERS. E. H. Mansfield and M. Fine. 1954. 43p. diagrs. (ARC R & M 2832; ARC 10,983. Formerly RAE Structures 6)

The effect of discrete, flexible ribs has been investigated and the results have been incorporated in a number of graphs which show the effect of rib-flexibility in a long thin-walled cylinder of arbitrary shape under end constraint. Some of the results of these investigations are of a negative character in that they show that for certain types of end conditions the effect of rib-flexibility is negligible. But rib-flexibility is of paramount importance when self-equilibrating shear-distorting forces are applied to a cylinder and this report makes the stress distribution in such a case readily determinable.

Aeronautical Research Council (Gt. Brit.)
AN ANALYSIS OF N. A. C. A. HELICOPTER REPORTS. R. N. Liptrot. 1954. 61p. diagrs., 5 tabs. (ARC CP 183)

Theory is compared with flight and model tests in order to obtain empirical correcting factors which will enable reliable performance estimates to be made for new helicopter designs. A survey of general theory is followed by an analysis of certain American reports. Correcting factors for effective blade drag for tip speed ratio, compressibility, and stalling of the retreating blade are derived. A method of calculating the retreating blade tip angle of attack for twisted blades is presented.

LOAD DIFFUSION IN PLASTIC STRUCTURES. L. M. Tucker and R. B. Twiss. 1955. 79p. diagrs., photos., 14 tabs. (ARC CP 186)

This report describes theoretical and experimental investigations of the inherent advantages, in plastic structures, of resin bonded shear joints over comparable pin joints, and the most efficient material distribution for load diffusion. Theoretical analysis and graphical solutions are developed to obtain the ideal distribution of material for load diffusion; these have general applicability to structural design.

HYDRAULIC FLUIDS, ETC.: THE DECREASE IN RATE OF FLOW ALONG TUBES OF A COLUMN OF LIQUID WHEN BROKEN BY AIR GAPS. G. F. N. Calderwood and E. W. J. Mardles. November 1954. 17p. diagrs., photos. (RAE Tech. Note Chem. 1242)

The loss of performance due to cavitation in a hydraulic system has been assessed by comparing observed times of flow with those calculated by means of the Poiseuille equation. Several air gaps of relatively small dimensions impart elastic and plastic resistance in addition to the normal viscous resistance so that the apparent viscosity may be several fold the bulk viscosity. An explanation of the increased resistance due to air gaps is attempted.

USE OF RADIO-ACTIVE ISOTOPES FOR DETECTING FUEL CONTAMINATION OF AIRCRAFT STRUCTURES. B. F. A. Gatward, H. W. G. Wyeth and D. J. Nosworthy October 1954. 8p. diagr., tab. (RAE Tech. Note Mech. Eng. 191)

Previous methods of determining the areas of contamination of an aircraft structure from fuel spilt from the tanks in flight have not been satisfactory as their application has been difficult and the results obtained uncertain. This note describes a convenient method of tracing the spread of spilt fuel by using fuel treated with radio-active compounds. It records the results of an investigation in which the method was used successfully. It was found that the best results were obtained when the radio-activity of the fuel was approximately 300 microcuries per gallon.

THE HOT-WIRE ANEMOMETER FOR TURBULENCE MEASUREMENTS. PART III. B. Wise and D. L. Schultz. March 24, 1954. 71p. diagrs. (ARC 16,679; FM 1527b; Oxford Univ., Engineering Lab. No. 69)

Further investigation of the operation of the hot-wire anemometer has shown that there are only two systems which are both statically stable and capable of improving the frequency response. A description is given of further experiments which have been made to verify the theory of operation of the wire, using both radio-frequency and direct current heating. An analysis of some feedback systems is given, and it is shown how these techniques may be used in the measurement of turbulence at high air speeds.

NEUTRAL HOLES IN LATERALLY LOADED PLATES HAVING SMALL DEFLECTIONS. R. Hicks. April 26, 1954. 43p. diagrs., photos. (ARC 16,768; Strut 1707)

Reinforced holes which do not alter the stress distribution in a plate are said to be neutral. In this discussion it is shown that a circular neutral hole can be cut in a laterally loaded plate providing there is a choice for the cross-sectional dimensions of the reinforcement. General expressions are derived which enable the cross-sectional dimensions of the reinforcement to be obtained from the expression for the deflection surface of a similarly loaded plate which has no hole. For some particular load systems considered, expressions are found for the cross-sectional dimensions of rings reinforcing circular neutral holes in plates whose boundaries are circular, rectangular, triangular, and elliptical. These expressions are used to solve typical numerical examples and it is found for all the cases considered that the cross-sectional dimensions of the ring are always practical.

VISCOUS EFFECTS ON PITOT TUBES AT LOW SPEEDS. F. A. MacMillan. June 15, 1954. 8p. diagrs., 2 tabs. (ARC 16,866; FM 2081)

Measurements were made of the pressure in a blunt-nosed pitot tube in an air stream at Reynolds numbers of 15 to 1,000. The results are expressed in terms of a pressure coefficient. This pressure coefficient becomes greater than 1 at low Reynolds numbers, the increase being about 1-1/2 percent at a Reynolds number of 50 (based on external tube radius). No decrease of the coefficient below 1 was found at any Reynolds number. When the values of the coefficient are plotted against Reynolds numbers based on internal tube radius, it is found that the curves are in closer agreement than when the external radius is used.

EXPERIMENTS IN THE COMPRESSED AIR TUNNEL ON SWEPTBACK WINGS INCLUDING TWO DELTA WINGS. R. Jones, C. J. W. Miles and P. S. Pusey. 1954. 26p. diagrs., 6 tabs. (ARC R & M 2871. Formerly ARC 11,354; Perf. 415)

Date are given relating to C_L, C_D, and C_m at high values of Reynolds number on wings of triangular planform, and at angles of attack from 0° to above the stall. Increasing the radius of the leading edge did not yield an improved $C_{L\ max}$ vs. R curve. Although the induced drag coefficient on the modified delta wing is somewhat less than on the original wing, the minimum-drag coefficient is greater.

PRESSURE PLOTTING AND BALANCE MEASUREMENTS IN THE HIGH SPEED WIND TUNNEL ON A HALF-MODEL OF A 90-DEG-APEX DELTA WING WITH FUSELAGE. A. C. S. Pindar and J. R. Collingbourne. 1954. 59p. diagrs., 5 tabs. (ARC R & M 2844; ARC 12,804. Formerly RAE Aero 2335)

Tests were made on a delta wing that had a taper ratio of 0.143 and a wing section of RAE 102, symmetrical, 10 percent thickness/chord at 35 percent chord. The tests were conducted at a Reynolds number of 1.8×10^6 and Mach numbers up to 0.93. These tests were designed to provide data on the surface pressures over a delta wing at high subsonic speeds. For comparison, balance measurements were also arranged. The pressure distributions were the most accurate and reliable of the results given.

NACA RM A50H24

FLIGHT CALIBRATION OF FOUR AIRSPEED SYSTEMS ON A SWEPT-WING AIRPLANE AT MACH NUMBERS UP TO 1.04 BY THE NACA RADAR-PHOTOTHEODOLITE METHOD. Jim Rogers Thompson, Richard S. Bray and George E. Cooper. October 27, 1950. 41p. diagrs., photos., tab. (NACA RM A50H24) (Declassified from Confidential, 3/11/55)

The characteristics of four different airspeed systems installed in a swept-wing airplane have been investigated in flight up to 1.04 Mach number by the NACA radar-phototheodolite method of airspeed calibration. The variations of static-pressure defect per unit indicated impact pressure with Mach number and a limited amount of information on the effect of airplane normal-force coefficient are presented for each system. The results are compared with available theory and wind-tunnel tests of the isolated heads.

NACA RM E50F29

SURVEY OF LESS-INFLAMMABLE HYDRAULIC FLUIDS FOR AIRCRAFT. Wray V. Drake and I. L. Drell. September 7, 1950. 64p. 14 tabs. (NACA RM E50F29) (Declassified from Confidential, 3/11/55)

A survey of current information on civil and military development of less-inflammable hydraulic fluids for aircraft is presented. Types of less-inflammable fluid reported include: glycol derivative, water base, silicone, ester, and halogenated compound. Specification requirements, physical and chemical properties, hydraulic-system test results, and advantages and disadvantages of various hydraulic fluids are discussed. For completely satisfactory service, some modification of currently available fluids or of present hydraulic-system parts still appears necessary.

NACA RM E53C12

THE DESIGN OF BRITTLE-MATERIAL BLADE ROOTS BASED ON THEORY AND RUPTURE TESTS OF PLASTIC MODELS. Andre J. Meyer, Jr., Albert Kaufman and William C. Caywood. April 6, 1953. 45p. diagrs., photos., tab. (NACA RM E53C12) (Declassified from Confidential, 3/11/55)

Theoretical design charts based on Neuber's equations for symmetrically located notches are presented for estimating the approximate rupture strengths of blade roots made from brittle materials. The limit of applicability of the theoretical charts is shown as determined by rupture tests of plastic models. The optimum proportions among overall root width, neck width, notch radius, and notch depth are determined from the design charts. Eighteen different root designs were investigated, their relative strengths were evaluated analytically and experimentally and the results were compared. A dovetail root having the optimum proportions as established by this investigation was the strongest root evaluated.

CURRENT NACA REPORTS

NACA TM 1371

APPARATUS FOR MEASUREMENTS OF TIME AND SPACE CORRELATION. (Appareil de Mesures de la Correlation Dans le Temps et L'Espace). A. Favre, J. Gaviglio and R. Dumas. (Presented at eighth International Congress for Theoretical and Applied Mechanics, Istanbul, Aug., 1952) April 1955. 20p. diagrs., photos. (NACA TM 1371. Trans. from La Rechèrche Aéronautique, no. 31, Jan.-Feb., 1953, p. 37-44).

A brief review is made of improvements to an experimental apparatus for time and space correlation designed for study of turbulence. Included is a description of the control of the measurements and a few particular applications.

NACA TM 1387

THEORY OF REVERSIBLE AND NONREVERSIBLE CRACKS IN SOLIDS. (Teoriya obratimykh i neobratimykh treshchin v tverdykh telakh). Y. I. Frenkel. April 1955. 14p. diagrs. (NACA TM 1387. Trans. from Zhurnal Tekhnicheskoi Fiziki, v. 22, no. 11, Nov., 1952, p. 1857-1866)

The Griffith crack theory is reviewed and certain shortcomings of this theory are discussed. A new description for the shape of a crack is given which takes into account the atomic structure of material. Through consideration of the total energy of the system and the shape of the crack, expressions for crack behavior are derived which are considered to remedy the defects of the Griffith theory.

NACA TN 3216

COOPERATIVE INVESTIGATION OF RELATIONSHIP BETWEEN STATIC AND FATIGUE PROPERTIES OF WROUGHT N-155 ALLOY AT ELEVATED TEMPERATURES. NACA Subcommittee on Heat-Resisting Materials. April 1955. 92p. diagrs., photos., 13 tabs. (NACA TN 3216)

Extensive data are given relating properties of N-155 alloy under static, combined static and dynamic, and completely reversed dynamic stress conditions. Time periods for fracture ranged from 50 to 500 hours at room temperature, 1,000°, 1,200°, 1,350°, and 1,500° F. The work was on a cooperative basis to help clarify the principles governing load-carrying ability of heat-resistant alloys at temperatures and conditions where both creep and fatigue can occur simultaneously. In view of the uncertainty in interpreting results of various types of fatigue tests, duplicate data were obtained from as many types of fatigue testing machines as could be arranged.

NACA TN 3270

EFFECT OF DISSOCIATION ON THERMODYNAMIC PROPERTIES OF PURE DIATOMIC GASES. Harold W. Woolley, National Bureau of Standards. April 1955. 19p. diagrs., tab. (NACA TN 3270)

A graphical method is described by which the enthalpy, entropy, and compressibility factor for the equilibrium mixture of atoms and diatomic molecules for pure gaseous elements may be obtained and shown for any dissociating element for which the necessary data exist. Results are given for hydrogen, oxygen, and nitrogen. The effect of dissociation on the heat capacity is discussed briefly.

NACA TN 3282

INTERGRANULAR CORROSION OF HIGH-PURITY ALUMINUM IN HYDROCHLORIC ACID. II - GRAIN-BOUNDARY SEGREGATION OF IMPURITY ATOMS. M. Metzger and J. Intrater, Columbia University. April 1955. 33p. diagrs., 4 tabs. (NACA TN 3282)

The variation in the rate of intergranular corrosion of single-phase high-purity aluminum in 20 percent hydrochloric acid as a function of iron content and final-annealing temperature is attributed to the segregation to atomic sites in the grain-boundary region of iron and possibly other impurity atoms. The experimental results are analyzed by reference to a distribution function, obtained by statistical mechanical methods, which gives the equilibrium fraction of certain sites in the boundary which are occupied by solute atoms in terms of the interaction energy for the segregation of the solute atoms at these sites.

NACA TN 3326

THE COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH HEAT TRANSFER AND ARBITRARY PRESSURE GRADIENT. Clarence B. Cohen and Eli Reshotko. April 1955. 43p. diagrs., 2 tabs. (NACA TN 3326)

An approximate method for the calculation of the compressible laminar boundary layer with heat transfer and arbitrary pressure gradient, based on Thwaites' correlation concept, is presented. With the definition of dimensionless shear and heat-transfer parameters and an assumed correlation of these parameters in terms of a momentum parameter, a complete system of relations for calculating skin-friction and heat-transfer results. Knowledge of velocity or temperature profiles is not necessary in using this calculation method. When the method is applied to a convergent-divergent, axially symmetric rocket nozzle, it shows that high rates of

heat transfer are obtained at the initial stagnation point and at the throat of the nozzle. Also indicated are negative displacement thicknesses in the convergent portion of the nozzle; these occur because of the high density within the lower portions of the cooled boundary layer.

NACA TN 3351

PLASTIC DEFORMATION OF ALUMINUM SINGLE CRYSTALS AT ELEVATED TEMPERATURES. R. D. Johnson, A. P. Young and A. D. Schwope, Battelle Memorial Institute. April 1955. 76p. diagrs., photos., 3 tabs. (NACA TN 3351)

A study was made of plastic deformation of aluminum single crystals over a wide range of temperatures. Results are presented of constant-stress creep tests, constant-load-rate tests, and constant-load creep tests. The effect of crystal orientation on the operative slip system was determined. The effect of small amounts of prestraining was studied and two high-resolution X-ray techniques were used to detect and follow the strain. Light and electron microscopy were used to study the complex nature of slip bands and kink bands on specimens deformed at elevated temperatures.

NACA TN 3370

A SIMPLIFIED METHOD FOR CALCULATING AEROELASTIC EFFECTS ON THE ROLL OF AIRCRAFT. John M. Hedgepeth, Paul G. Waner, Jr. and Robert J. Kell. March 1955. 26p. diagrs., 4 tabs. (NACA TN 3370)

An approximate linearized lifting-surface theory is used in conjunction with structural influence coefficients to formulate a method for analyzing the aeroelastic behavior in roll of an aircraft. Rolling effectiveness and aileron-reversal speed are computed by the use of a Galerkin-type procedure. Results obtained for two example configurations by using this method are compared with the results obtained by using the more refined method of NACA TN 3067.

NACA TN 3373

THEORETICAL CALCULATIONS OF THE PRESSURES, FORCES, AND MOMENTS DUE TO VARIOUS LATERAL MOTIONS ACTING ON THIN ISOLATED VERTICAL TAILS WITH SUPERSONIC LEADING AND TRAILING EDGES. Kenneth Margolis. March 1955. 43p. diagrs., 10 tabs. (NACA TN 3373)

Expressions based on linearized thin-airfoil theory for supersonic speeds are derived for the velocity potentials and pressure distributions due to various lateral motions for a family of thin isolated vertical tails with arbitrary sweepback and taper ratio. Motions treated are steady rolling, steady yawing, constant sideslip, and constant lateral acceleration. For the particular cases of half-delta and rectangular vertical tails, forces and moments expressed in the form of stability derivatives are also derived and presented in simple charts. All results are, in general, applicable at those supersonic speeds for which both the tail leading and trailing edges are supersonic. End-plate effects for several of the derivatives are also considered.

NACA TN 3376

THE EFFECT OF CONTROL STIFFNESS AND FORWARD SPEED ON THE FLUTTER OF A 1/10-SCALE DYNAMIC MODEL OF A TWO-BLADE JET-DRIVEN HELICOPTER ROTOR. George W. Brooks and Maurice A. Sylvester. April 1955. 38p. diagrs., photo., 3 tabs. (NACA TN 3376)

Some tests have been made with a 1/10-scale dynamic model of a two-blade jet-drive helicopter to study the effects of blade-pitch-control stiffness and tip-speed ratio on the rotor blade flutter characteristics. The results showed that the flutter speed of the model blades was increased as the blade-pitch-control stiffness was increased and indicated that the structural blade modes of primary importance with respect to flutter were the first torsion mode and the flapping mode. The rotor speed at flutter was reduced slightly as the tip-speed ratio was increased from hovering to forward flight.

NACA TN 3383

INVESTIGATION OF THE TURBULENT BOUNDARY LAYER ON A YAWED FLAT PLATE. Harry Ashkenas and Frederick R. Riddell, Cornell University. April 1955. 57p. diagrs., photos. (NACA TN 3383)

Experiments carried out on three flat plates yawed 0°, 30°, and 45° with artificially fixed transition in a low-speed, low-turbulence tunnel are described. The effects of yaw on the velocity profile and on the direction of flow near the plate are found to be small. The boundary-layer displacement thickness on a yawed plate is found to grow in the streamwise direction at a rate slightly greater than it does on the unyawed plate; this is in contrast with the laminar case where the "independence principle" discovered by Prandtl and others leads to a substantially reduced rate of growth on yawed plates.

NACA TN 3392

TWO MINIATURE TEMPERATURE RECORDERS FOR FLIGHT USE. John V. Foster. April 1955. 13p. diagrs., photos. (NACA TN 3392)

Descriptions are given for two types of temperature recorders suitable for use with thermocouples on fighter-type aircraft. One is an electromechanical self-balancing potentiometer type; the other uses electronic feedback to achieve fast balance.

NACA TN 3393

AN EXPERIMENTAL INVESTIGATION OF THE BASE PRESSURE CHARACTERISTICS OF NONLIFTING BODIES OF REVOLUTION AT MACH NUMBERS FROM 2.73 TO 4.98. John O. Reller, Jr. and Frank M. Hamaker. March 1955. 45p. diagrs., photos. (NACA TN 3393. Formerly RM A52E20)

Base pressure characteristics of related nonlifting bodies of revolution were investigated at free-stream Mach numbers from 2.73 to 4.98 and Reynolds numbers from 0.6×10^6 to 8.8×10^6. The basic body shape was a 10-caliber tangent ogive with a cylindrical afterbody. The variation of base pressure coefficient with free-stream Mach number and

Reynolds number was determined for laminar-, transitional-, and turbulent-boundary-layer flow. Some effects of body fineness ratio, nose-profile shape, and afterbody shape (boattail) were also included in the investigation.

NACA TN 3420

HYDRODYNAMIC TARES AND INTERFERENCE EFFECTS FOR A 12-PERCENT-THICK SURFACE-PIERCING STRUT AND AN ASPECT-RATIO-0.25 LIFTING SURFACE. John A. Ramsen and Victor L. Vaughan, Jr. April 1955. 20p. diagrs. (NACA TN 3420)

Results are presented from an investigation of the hydrodynamic tares and interferences acting on an NACA 66_1-012 airfoil-section surface-piercing strut and an aspect-ratio-0.25 modified-flat-plate rectangular lifting surface. The interference of the strut on the lifting surface was negligible except at very shallow depths, where it increased the lift and pitching moment slightly. Strut-tare effects were appreciable only on drag, where section-drag coefficients showed good agreement with data from previous tank and wind-tunnel tests. The surface-intersection drag coefficients were constant above the critical wave speed and showed fairly good agreement with wave-drag theory below the critical speed.

NACA TN 3426

AN EXPERIMENTAL STUDY OF ORIFICE COEFFICIENTS, INTERNAL STRUT PRESSURES, AND LOADS ON A SMALL OLEO-PNEUMATIC SHOCK STRUT. James H. Walls. April 1955. 23p. diagrs., photos. (NACA TN 3426)

Measurements of shock-strut internal pressures, telescoping velocity, and strut stroke were made during drop tests of a small oleo-pneumatic landing gear to determine the characteristics of the orifice and to show the relationships between internal strut pressures and the overall loads developed by the strut. The variation of the orifice coefficient with telescoping velocity and strut stroke is presented. Strut forces determined from internal-pressure measurements are compared with forces measured by an external dynamometer. Strut forces calculated from measured telescoping velocity and stroke time histories are evaluated, a constant orifice coefficient and isothermal air compression being assumed.

NACA TN 3428

GROUND-SIMULATOR STUDY OF THE EFFECTS OF STICK FORCE AND DISPLACEMENT ON TRACKING PERFORMANCE. Stanley Faber. April 1955. 21p. diagrs., photos. (NACA TN 3428)

Tests were performed on a ground simulator with one degree of freedom, pitch, to determine the desired magnitude of the control-stick forces and displacements in relation to the performance of a tracking task. The dynamics of the simulated airplane were typical of those of current fighters operating at low altitudes and at subsonic speeds and having an undamped natural frequency of 1/2 cycle per second and a damping ratio of approximately 0.8.

NACA TN 3429

STATIC STABILITY OF FUSELAGES HAVING A RELATIVELY FLAT CROSS SECTION. William R. Bates. March 1955. 29p. diagrs., tab. (NACA TN 3429. Formerly RM L9I06a)

The subject investigation contains results of force tests and flow surveys made in the Langley free-flight tunnel to determine the static stability characteristics of several fuselages having a relatively flat cross section and a high fineness ratio.

NACA TN 3430

ON SLENDER DELTA WINGS WITH LEADING-EDGE SEPARATION. Clinton E. Brown and William H. Michael, Jr. April 1955. 27p. diagrs. (NACA TN 3430)

The slender-body approximation of linearized compressible flow is applied to the problem of a delta wing in which flow separation occurs at the leading edges. The vortex sheets found in the real flow are approximated by concentrated vortices with feeding lattices, and an adaptation of Kelvin's theorem is applied to simulate the force-free nature of the vortex sheet. Computed pressure distributions and span loadings are presented, and the theoretical lift results are compared with the results of simple force tests made at a Mach number of 1.9.

NACA TN 3431

AN ANALYSIS OF THE STABILITY AND ULTIMATE COMPRESSIVE STRENGTH OF SHORT SHEET-STRINGER PANELS WITH SPECIAL REFERENCE TO THE INFLUENCE OF RIVETED CONNECTION BETWEEN SHEET AND STRINGER. Joseph W. Semonian and James P. Peterson. March 1955. 49p. diagrs., tab. (NACA TN 3431)

A method of strength analysis of short sheet-stringer panels subjected to compression is presented which takes into account the effect that the riveted attachments between the plate and the stiffeners have on the strength of panels. An analysis of experimental data shows that panel strength is highly influenced by rivet pitch, diameter, and location and that the degree of influence for a given riveting depends on the panel configuration and panel material.

NACA TN 3432

CIRCUMFERENTIAL DISTRIBUTION OF PROPELLER-SLIPSTREAM TOTAL-PRESSURE RISE AT ONE RADIAL STATION OF A TWIN-ENGINE TRANSPORT AIRPLANE. A. W. Vogeley and H. A. Hart. April 1955. 24p. diagrs., photos. (NACA TN 3432)

Flight tests on a twin-engine transport airplane have been made to determine the effects of fuselage-nacelle interference on the circumferential distribution of the rise in total pressure behind the propellers. The effects of this flow interference on the operation of a simple propeller-thrust indicator, which samples the total-pressure rise at two diametrically opposed points in the slipstream (to counteract the effects of variations in angles of pitch and yaw), have been investigated.

NACA TN 3434

A STUDY OF NORMAL ACCELERATIONS AND OPERATING CONDITIONS EXPERIENCED BY HELICOPTERS IN COMMERCIAL AND MILITARY OPERATIONS. Marlin E. Hazen. April 1955. 34p. diagrs., photos., 5 tabs. (NACA TN 3434)

An analysis is presented of the normal accelerations and operating conditions encountered by two different airmail helicopters and a military pilot-training helicopter. Tables and graphs are used to illustrate the effect of operating conditions on acceleration levels, and a summary of all NACA helicopter VGH data analyzed to date is included.

NACA TN 3446

EFFECT OF AMMONIA ADDITION ON LIMITS OF FLAME PROPAGATION FOR ISOOCTANE-AIR MIXTURES AT REDUCED PRESSURES AND ELEVATED TEMPERATURES. Cleveland O'Neal, Jr. April 1955. 32p. diagrs., 3 tabs. (NACA TN 3446)

Limits were determined for isooctane, ammonia, and mixtures of these two fuels with air at pressures up to 400 mm Hg and temperatures from 60° to 400° C. In the ternary mixtures, NH_3-air weight ratios were 0.020 and 0.039. For all mixtures, the flammable region (rich minus lean limit equivalence ratio) broadened as the temperature was raised. The flammable region of isooctane was roughly three times that of ammonia. However, small additions of ammonia to isooctane broadened the flammable range up to an NH_3-air ratio of about 0.02; further additions narrowed the range. Added ammonia was completely consumed in lean mixtures; in rich mixtures about half of the ammonia was unburned.

NACA TN 3447

ANALYTIC DETERMINATION OF THE DISCHARGE COEFFICIENTS OF FLOW NOZZLES. Frederick S. Simmons. April 1955. 15p. diagrs. (NACA TN 3447)

An analytic expression for the discharge coefficient of flow nozzles is obtained by integration of an approximation for the velocity profile through the cross section of the nozzle. This expression shows the discharge coefficient to be a function of the Reynolds number and the geometry of the nozzle and agrees well with published experimental data for Reynolds numbers between 10^4 and 10^6.

NACA TN 3496

FLIGHT TESTING BY RADIO REMOTE CONTROL - FLIGHT EVALUATION OF A BEEP-CONTROL SYSTEM. Howard L. Turner, John S. White and Rudolph D. Van Dyke, Jr. March 1955. 55p. diagrs., photos., tab. (NACA TN 3496. Formerly RM A52A29)

A comparison between manual control and remote control showed that a beep-type, radio-remote-control system was, in general, a satisfactory means of control for conducting standard handling-quality flight tests. The dynamic characteristics of the airplane-autopilot combination and the selection of the proper parameter adjustments are discussed.

BRITISH REPORTS

Aeronautical Research Council (Gt. Brit.)
DIFFUSION OF ANTISYMMETRICAL LOADS INTO, AND BENDING UNDER, TRANSVERSE LOADS OF PARALLEL STIFFENED PANELS. J. H. Argyris. 1954. 52p. diagrs. (ARC R & M 2822. Formerly ARC 9662; Strut 1037)

The purpose of this paper is to present the general theory of diffusion of antisymmetrical concentrated end loads and edge loads into parallel stiffened panels, including the theory of bending of a parallel stiffened panel under arbitrary transverse loads. By combining the results of this paper with the results on diffusion of symmetrical loads given in R & M 1969 and R & M 2038 or in Appendix I to this paper, it is possible to analyze the diffusion in a parallel panel under any arbitrary load or edge stress distribution.

Aeronautical Research Council (Gt. Brit.)
THE DETERMINATION OF THE PRESSURE DISTRIBUTION OVER AN AEROFOIL SURFACE BY MEANS OF AN ELECTRICAL POTENTIAL ANALYSER. S. C. Redshaw. 1954. 40p. diagrs., photos., tabs. (ARC R & M 2915; ARC 15,733. Formerly Boulton Paul Aircraft Ltd. Tech. Rept. 101)

The potential flow, both with and without circulation around several thin wings has been studied by means of a three-dimensional potential analyzer. It is shown that, by using the normal assumptions made in the exercise of the linear perturbation theory, it is possible to obtain the pressure distribution for small angles of attack, as well as the slope of the lift-incidence curve, easily and rapidly. Experiments are also described in which it was attempted to remove the effect of boundary restraint in a manner analogous to that used in a flexible walled wind tunnel.

BOUNDARY LAYER MEASUREMENTS ON 10° AND 20° CONES AT M = 2.45 AND ZERO HEAT TRANSFER. E. V. Davies and J. R. Cooke. November 1954. 62p. diagrs., photos., 2 tabs. (RAE Tech. Note Aero 2314)

Transition from laminar to turbulent flow occurred between 4 and 6 in. from the tip of the 10° cone at Reynolds number between 10^6 and 1.4×10^6; the layer on the 20° cone was laminar over its entire length of 6 in. (Reynolds number = 1.4×10^6). Results agree well with the flat plate solution of Monaghan transformed by the theoretical cone-flat plate relations of Hantzsche and Wendt, and Mangler. The data for the turbulent boundary layer were obtained from the 10° cone and comparison with flat plate data indicates that the cone-flat plate relation is within 6 percent of an empirical relation analogous to the $\sqrt{3}$ laminar boundary layer factor.

A FLIGHT INVESTIGATION OF THE WAKE BEHIND A METEOR AIRCRAFT, WITH SOME THEORETICAL ANALYSIS. D. R. Andrews. December 1954. 38p. diagrs., photos., tab. (RAE Tech. Note Aero 2283)

The jet velocity falls to a negligible value by 200-300 feet behind the jet exit. Major disturbances behind an aircraft are due to the trailing vortices and these decay only slowly. Tests with a Vampire flying in the wake show that the strength of these vortices has fallen to about half its initial value by 8000 feet behind the aircraft. Theory and flight tests show that the rolling moment imposed on a tracking aircraft constitutes the most severe disturbance from these vortices, and in some cases this rolling moment can be large enough to overpower the aileron control of the tracking aircraft.

CURRENT INTERRUPTION OF D.C. CIRCUITS IN AIR AT LOW PRESSURES, WITH SPECIAL REFERENCE TO THE ARC CHARACTERISTIC BETWEEN SILVER ELECTRODES. A. H. M. Arnold and L. H. Ford. July 1954. 34p. diagrs., 11 tabs. (RAE EL. 1485)

Measurements have been made of the voltage and current in d-c arcs over a range of air pressures using silver, copper, and tungsten electrodes. The investigation has shown that although the arc characteristic at low pressures is less favorable for breaking large currents than it is at atmospheric pressure, comparable switch performance may usually be obtained either by an increase of gap length, or by an increase in the number of series breaks. Simple empirical relationships for the arc characteristics based on the experimental data obtained are given for silver and tungsten electrodes: tests on the interrupting capacity of switches gave results which were in reasonable agreement with predictions made from these empirical formulas.

SOME EXPERIMENTS ON RATES OF QUENCHING. F. J. Bradshaw and S. Pearson. October 1954. 11p. diagrs. (RAE Tech. Note Met. 203)

Experiments are described on the quenching rates of 6.4 mm diameter cylindrical specimens in water at various temperatures. Similar work is described using cylinders and wires (1.2 to 0.3 mm) quenched in liquids held at temperatures below 0° C. Appropriate mean values of surface heat transfer coefficients are deduced.

28 S.W.G. TITANIUM SHEETING FOR FIREPROOF BULKHEADS. J. T. Ballett. September 1954. 7p. photos., 2 tabs. (RAE Tech. Note Met. 202)

Tensile and bend tests were made on 28 S.W.G (0.015 in.) Ti 75A titanium sheet in the annealed condition and also after exposure in a furnace at 1000° C for 5 minutes. Exposure tests were also carried out using two different types of torch flames. The results showed that the heating to 1000° C increased the tensile strength of the material by about 20 percent to 49 tons/sq in., with an accompanying reduction in elongation from 28 percent to 4 percent.

SELECTIVITY IN THE FORMATION OF FATIGUE CRACKS DURING THE WORKING OF STEEL IN A CORROSIVE MEDIUM; AND ADSORPTIVE BEGINNING OF THE CORROSIVE FATIGUE OF METALS. (Pro Vibirnist' v Utvorenni Trishchin Vtomi pri Roboti Stali u Koroziynomu Seredovishchi, and Adsorbtsiinii Pochatok Koroziinoi Vtomi Metaliv). G. V. Karpenko. 11p. diagrs., photos. (Trans. from Akademiia Nauk URSR, Kiev, Dopovidi, no. 2, 1951, p. 112-119)

In part I, steel was tested under reversed torsion in air and aerated water. Transcrystalline cracks perpendicular to the maximum tensile stress were observed. All cracks were found to be normal to the surface. In part II, the effects of an actively corrosive media as well as a superficially corrosive one were considered.

Univ. of Calif., Berkeley. Institute of Engineering Research. A MACH 3.106 TWO-DIMENSIONAL ADJUSTABLE NOZZLE FOR LOW DENSITY FLOW (NO. 10 NOZZLE). L. Talbot. February 18, 1954. (iii), 29p. diagrs., photos., 3 tabs. (Univ. of Calif., Berkeley. Institute of Engineering Research. HE-150-120)

Following the results of tests conducted in a small wind tunnel, a Mach 3.106 adjustable throat two-dimensional nozzle was designed for the No. 3 Wind Tunnel of the Low Pressures Project. The nozzle measured 11.05 in. from throat to exit and, including boundary-layer corrections, had exit dimensions of 3.899 in. x 4.116 in. Test section Mach numbers from 2.50 to 6.53 were produced by varying the nozzle throat height. The uniform flow region decreased with increased Mach number; at the highest Mach number the nozzle was completely filled with boundary layer.

Polytechnic Institute of Brooklyn. THE NON-LINEAR DEFLECTION OF INFINITE STRIP PLATES. F. S. Shaw, F. Pohle and N. Perrone. June 1953. 16p. diagrs., tab. (Polytechnic Institute of Brooklyn. PIBAL 225)

By expressing the von Kármán plate theory entirely in terms of displacements, there result three simultaneous nonlinear governing equations. These are not readily soluble. If, however, the plate is taken to be an infinite strip, and the loading to vary on in the finite direction, solutions can be obtained for a variety of loading cases. This restricted class of problems is discussed here, and the solution for the case of uniform loading is considered in all detail.

Polytechnic Institute of Brooklyn. THE NONLINEAR DEFLECTION OF AN INFINITE STRIP MEMBRANE. N. Perrone, F. Pohle and F. S. Shaw. April 1953. 13p. diagr. (Polytechnic Institute of Brooklyn. PIBAL Rept. 219)

The problem of the nonlinear deflection of a membrane having the shape of an infinite strip is considered. By setting up the problem in terms of displacement components, it is shown that it is possible to obtain exact, simple, closed form solutions for a variety of loading cases which are subject to the restriction that variation is in the finite direction only.

Univ. of Okla. Research Institute. FLAME STABILIZATION RESULTING FROM CYCLONIC FLOW IN MIXTURES OF NATURAL GAS AND AIR. Lyle F. Albright and Lloyd G. Alexander. (Final rept. for period June 4, 1952 to June 30, 1954). viii, 108p. diagrs., photos., 26 tabs. (Univ. of Okla. Research Institute)

The application of cyclonic flow to the combustion of natural gas-air mixtures in emergent cyclonic free jets, ducts, and diverging sections has been investigated. The investigation consists of quantitative measurements to determine the characteristics and stability limits of the flames obtained. In addition, directional impact and static pressure tube measurements were made in the flow fields of emergent cyclonic free jets, so that the explanation to flame stabilization due to cyclonic motion could be conclusively established.

Brown Univ., Providence, R.I. Div. of Applied Mathematics. REMARKS ON TRANSFORMS AND BOUNDARY VALUE PROBLEMS. P. Germain. June 1954. 34p. (Brown Univ., Providence, R.I. Div. of Applied Mathematics)

An attempt is made to show the relations between transforms and simple boundary value problems. Some general formulas show in fact that the Fourier integral theorem, the Fourier Dini integral theorem and many of the consequences which can be derived from them may easily be generalized. The same formulas can be applied as well to elliptic as to hyperbolic problems. It does not seem to be possible to obtain correspondingly simple results for the case of problems related to an equation of mixed type. As an application of the approach, the interpretation of a result, called a generalized Hankel Transform, was made precise. The method and the results may be extended to the case of finite transforms.

Brown Univ., Providence, R.I. Div. of Applied Mathematics. AN EXPRESSION FOR THE GREEN'S FUNCTION FOR A PARTICULAR TRICOMI PROBLEM. P. Germain. June 1954. 34p. diagrs. (Brown Univ., Providence, R.I. Div. of Applied Mathematics)

The Tricomi equation is written with new independent variables; this new form allows one to write the Green's function for a special Tricomi problem in the form of a Mellin Transform. The analysis is greatly simplified by the use of a technique previously used by R. Bader and the author. Corresponding formulas for the doublet are given. These results are given in a form which can be used for numerical computation. Using the same method, a generalized Tricomi problem is discussed. The results may be used in order to simplify the existence proof for a solution of a Tricomi problem for the Tricomi equation.

NACA Rept. 1169

MATRIX METHODS FOR DETERMINING THE LONGITUDINAL-STABILITY DERIVATIVES OF AN AIRPLANE FROM TRANSIENT FLIGHT DATA. James J. Donegan. 1954. ii, 20p. diagrs., 6 tabs. (NACA Rept. 1169. Formerly TN 2902)

Three methods are presented for calculating the longitudinal stability derivatives from transient flight data. Several examples using flight data are given to illustrate the method. The results indicate the scatter which is typical of this type of analysis.

NACA TN 3349

APPLICATION OF THE GENERALIZED SHOCK-EXPANSION METHOD TO INCLINED BODIES OF REVOLUTION TRAVELING AT HIGH SUPERSONIC AIRSPEEDS. Raymond C. Savin. April 1955. 71p. diagrs., photos., tab. (NACA TN 3349)

The generalized shock-expansion method is applied to obtain solutions to the flow field about pointed bodies of revolution at high supersonic airspeeds and small angles of attack. Simple explicit expressions are obtained for the surface Mach numbers and surface pressures in the special case of slender bodies. In the case of inclined cones, algebraic solutions are obtained defining the entire flow field. Experimental pressure-distribution data for cones and ogives at Mach numbers from 3 to 5 are included.

NACA TN 3372

FLIGHT MEASUREMENTS OF BASE PRESSURE ON BODIES OF REVOLUTION WITH AND WITHOUT SIMULATED ROCKET CHAMBERS. Robert F. Peck. April 1955. 18p. diagrs., photo. (NACA TN 3372. Formerly RM L50I28a)

Base pressures were measured on fin-stabilized bodies of revolution with and without rocket chambers and with and without a converging afterbody. At Mach numbers between 0.7 and 1.2, the results show that the presence of a "cold" rocket chamber increased the pressure (less suction) over the center portion of the bases. The effects of rocket chambers on pressures near the edge of the bases were not as consistent throughout the Mach number range nor as appreciable at most speeds as were the effects on pressures measured on the center line.

NACA TN 3406

A SELF-EXCITED, ALTERNATING-CURRENT, CONSTANT-TEMPERATURE HOT-WIRE ANEMOMETER. Charles E. Shepard. April 1955. 29p. diagrs., photos. (NACA TN 3406)

The hot-wire anemometer described herein was used to study turbojet-engine compressor rotating stall and surge. The system was capable of measuring flow over a frequency range of zero to 500 cycles per second. A self-sustaining, 8 kilocycle-per-second oscillation was used to heat the wire in a constant-temperature system. The relatively rugged, large-diameter wire allowed the use of the anemometer during the full-scale performance testing of compressors and turbojet engines. The commercial audio-frequency amplifier used reduced the cost and the time required to build the anemometer.

NACA TN 3410

VARIATION OF LOCAL LIQUID-WATER CONCENTRATION ABOUT AN ELLIPSOID OF FINENESS RATIO 10 MOVING IN A DROPLET FIELD. Rinaldo J. Brun and Robert G. Dorsch. April 1955. 51p. diagrs., photo., tab. (NACA TN 3410)

Trajectories of water droplets about an ellipsoid of revolution with a fineness ratio of 10 (10 percent thick) in flight through a droplet field were computed with the aid of a differential analyzer. Analyses of these trajectories indicate that the local concentration of liquid water at various points about an ellipsoid varies considerably and under some conditions may be several times the free-stream concentration. Curves of the local concentration factor as a function of spatial position were obtained and are presented in terms of dimensionless parameters that describe flight and atmospheric conditions.

NACA TN 3423

METHOD OF CONTROLLING STIFFNESS PROPERTIES OF A SOLID-CONSTRUCTION MODEL WING. Norman S. Land and Frank T. Abbott, Jr. April 1955. 21p. diagrs., photos., tab. (NACA TN 3423)

A simple method is presented for controlling the bending and torsional stiffnesses of a solid-construction model wing. The method consists of weakening the wing by drilling holes through the wing normal to the chord plane. Aerodynamic continuity is maintained by filling the holes with a relatively soft material. The important parameters controlling the stiffnesses are the amount of material removed by drilling the ratio of hole diameter to wing thickness, and the plan-form pattern of the holes. Data are given which may be used for predicting the stiffness of a model wing weakened in this manner.

NACA TN 3435

A STATISTICAL STUDY OF WING LIFT AT GROUND CONTACT FOR FOUR TRANSPORT AIRPLANES. Dean C. Lindquist. April 1955. 18p. diagrs., tab. (NACA TN 3435)

A brief statistical study of the value of the wing-lift factor K_L at the instant of ground contact during landing is presented for four transport airplanes. Frequency distributions and probability distributions of the wing-lift factor were determined from acceleration measurements on VGH records of 2,049 landings in routine airline operations. The results indicate that the mean value of K_L is very nearly 1, that in 95 percent of all the landings the lift factor did not vary from the mean value by more than ± 0.1, and that the probability of obtaining a value of K_L as low as 0.8 or as high as 1.2 is approximately 1 in 10,000.

NACA TN 3437

PRELIMINARY INVESTIGATION OF A SUBMERGED AIR SCOOP UTILIZING BOUNDARY-LAYER SUCTION TO OBTAIN INCREASED PRESSURE RECOVERY. Mark R. Nichols and P. Kenneth Pierpont. April 1955. 72p. diagrs., photos., 2 tabs. (NACA TN 3437. Formerly RM L50A13)

This paper presents results of low-speed tests of a submerged inlet consisting essentially of a conventional scoop located in a dimple in the fuselage surface. Boundary-layer-control systems investigated are shown to provide important increases in performance. It appears that the flow instability frequently encountered in the case of twin internally coupled inlets will be avoided for design high-speed inlet-velocity ratios as low as 0.5.

NACA TN 3445

DESIGN AND PERFORMANCE OF THROTTLE-TYPE FUEL CONTROLS FOR ENGINE DYNAMIC STUDIES. Edward W. Otto, Harold Gold and Kirby W. Hiller. April 1955. 39p. diagrs., photo. (NACA TN 3445)

The results of an analytical and experimental investigation of the steady-state and dynamic characteristics of three types of throttle-controlled fuel systems are presented. The investigation covers the effect of output pressure on the controlled flow and the dynamic response of output flow to throttle movement. Results show that linearized analysis provides an adequate description of the dynamic response. The best system tested showed a usable frequency response to 300 cycles per second.

NACA TN 3498

EXPLORATORY INVESTIGATION OF AN AIRFOIL WITH AREA SUCTION APPLIED TO A POROUS, ROUND TRAILING EDGE FITTED WITH A LIFT-CONTROL VANE. Robert E. Dannenberg and James A. Weiberg. April 1955. 55p. diagrs., photos., 2 tabs. (NACA TN 3498)

A two-dimensional wind-tunnel investigation has been made of an NACA 65_1-012 airfoil modified with a porous, round trailing edge fitted with a small vane. Area suction was applied and the vane was used to fix the rear stagnation point. The effects of variations of the chordwise extent of suction and of the vane geometry were investigated with the aim of attaining high maximum lift with low suction quantity.

AN INVESTIGATION OF THE TEMPERATURE GRADIENTS ARISING FROM KEROSENE FIRES ON WATER. Jean Birchall, M. D. Knowles and J. A. Campbell. November 1954. 11p. diagrs., photos. (RAE Tech. Note Mech. Eng. 192)

When kerosene is burning on the surface of still water for short periods, the upper layer of water will reach boiling point, but there is a negligible temperature change at depths greater than 1 inch. Temperature gradients of the order of 600° C per inch, measured in the vertical plane, occur immediately above the water level, and of 100° C per inch, immediately below. Clearly defined effects are produced on metal specimens partially submerged in the water.

PRESSURE LAG IN PIPES WITH SPECIAL REFERENCE TO AIRCRAFT SPEED AND HEIGHT MEASUREMENTS. Keith Smith. November 1954. 33p. diagrs., photos. (RAE Aero 2507)

A new method of applying lag corrections in flight is presented. It is based on the results of ground tests employing simulated steady dives and is shown to be more accurate than the method of Charnley using the response to a step input. The errors involved in measurement of lag in a pull-out are considered theoretically and are shown to be just appreciable in certain cases. Instrument lag is also briefly touched upon. A routine procedure for lag correction in flight is given.

THE DETERMINATION OF COEFFICIENTS OF HEAT TRANSFER TO A ROCKET MOTOR NOZZLE BY A TRANSIENT METHOD: PART II. W. S. Long. December 1954. 19p. diagrs., 2 tabs. (RAE Tech. Note RPD 114)

The measurements of heat transfer described in this note were made using a solid copper nozzle with an internal profile symmetrical about the throat. By this means it was possible to determine values at the throat of the nozzle and in the subsonic and supersonic regions of gas flow. The rate of heat transfer across the gas boundary layer was measured by determining the quantity of heat conducted into the nozzle by the transient measurement of temperatures at various points within it during the running time of the motor. The main purpose of the five firings described was to check the reproducibility of temperature measurements before embarking upon a comprehensive program. The reproducibility was found to be good.

THE USE OF RESIN-GLASS LAMINATES FOR BATTERY CONTAINERS. M. M. Cornford and E. Haythornthwaite. November 1954. 16p., 7 tabs. (RAE Tech. Note Chem. 1241)

A study has been made of the factors affecting the resistance of glass fabric-resin fabrications to battery acid with a view to their use in battery containers. Polyester resins can be obtained which are resistant to the attack of the electrolyte. Low alkali glass is seriously attacked by battery acid and the use of high alkali glass in this application is recommended. Increased resistance of polyester resin glass fabric laminates to attack by battery acid is obtained if a finish is applied to the glass surface to obtain the strongest possible resin to glass bond on lamination.

Ministry of Supply (Gt. Brit.)
RESEARCH ON MOULDED DURESTOS AIRCRAFT STRUCTURES. FINAL REPORT - JUNE 1954. 161p. diagrs., photos., 53 tabs. (Ministry of Supply. S & TM 15/54)

The problem in this investigation was to establish a method of design and manufacture for certain type wing structures in the plastic material Durestos. The main objectives were to achieve efficiency on a strength-weight basis and a high rate of production at a cost far less than that normally associated with aircraft manufacture. It has been established that the first object can be met. In regard to the second object, further work on two different lines relating to workshop technology would need developing before mass production could be undertaken without risk of delays; the first relates to moulding tool manufacture while the second relates to "flock injection moulding" of the wing stiffening structure, for example, rib and spanwise internal flanges.

DECLASSIFIED NACA REPORTS

NACA RM E51C27

CRITERIONS FOR PREDICTION AND CONTROL OF RAM-JET FLOW PULSATIONS. William H. Sterbentz and John C. Evvard. May 16, 1951. 63p. diagrs., photos. (NACA RM E51C27) (Declassified from Confidential, 4/14/55)

Results of a theoretical and experimental study of ram-jet diffuser flow pulsing, commonly referred to as a "buzz condition," with and without combustion are presented. The theoretical approach to the problem is a simplified treatment of the ram jet likened to act as a Helmholtz resonator. The theoretical resonance criterions reasonably predicted the occurrence of diffuser-flow pulsations.

NACA RM E51D19

EXPERIMENTAL INVESTIGATION OF TYPICAL CONSTANT- AND VARIABLE-AREA EXHAUST NOZZLES AND EFFECTS ON AXIAL-FLOW TURBOJET-ENGINE PERFORMANCE. Lewis E. Wallner and John T. Wintler. July 1951. 43p. diagrs., photos. (NACA RM E51D19) (Declassified from Confidential, 4/14/55)

A study of the performance of constant- and variable-area exhaust nozzles and their effects on turbojet engines has been made from data obtained in the NACA Lewis altitude wind tunnel. The aspects covered include exhaust-nozzle velocity and flow coefficients at pressure ratios up to 3.6, a comparison of full- and small-scale nozzle data, and influence of exhaust nozzles on engine specific fuel consumption, thrust control, and afterburner performance.

NACA RM E52D30

INVESTIGATION OF POWER EXTRACTION CHARACTERISTICS AND BRAKING REQUIREMENTS OF A WINDMILLING TURBOJET ENGINE. Curtis L. Walker and David B. Fenn. July 1952. 31p. diagrs., tab. (NACA RM E52D30) (Declassified from Confidential, 4/14/55)

An investigation was conducted in an altitude chamber at the NACA Lewis Laboratory to determine the power extraction and braking characteristics of a windmilling single-spool axial-flow turbojet engine of the 5000-pound thrust class over a range of altitudes from 5000 to 50,000 feet and flight Mach numbers from 0.2 to 1.0. The constant applied torque required to stop the rotation of a windmilling engine in 0.2 minute at a simulated altitude of 40,000 feet was found to be 99 foot-pounds at a flight Mach number of 0.2 and 620 foot-pounds at a flight Mach number of 1.0. The torque required to stop the engine in 0.2 minute at a flight Mach number of 0.4 decreased from 290 foot-pounds as altitude was increased from 5000 to 50,000 feet.

NACA RM E52I24

AMPLITUDE OF SUPERSONIC DIFFUSER FLOW PULSATIONS. William H. Sterbentz and Joseph Davids. December 1952. 23p. diagrs. (NACA RM E52I24) (Declassified from Confidential, 4/14/55)

A theoretical method for evaluating the stability characteristics and the amplitude and frequency of pulsation of ram-jet engines without heat addition is presented. Theory and experiment show that the pulsation amplitude of a high-mass-flow ratio diffuser having no cone surface flow separation increases with decreasing mass flow. The theoretical trends for changes in amplitude, frequency, and mean-pressure recovery with changes in plenum-chamber volume were experimentally confirmed. For perforated, convergent-divergent-type diffusers, theory and experiment show the existence of a stability hysteresis loop on the pressure-recovery mass-flow-ratio curve.

NACA RM L52A18

AN ANALYSIS OF BUZZING IN SUPERSONIC RAM JETS BY A MODIFIED ONE-DIMENSIONAL NON-STATIONARY WAVE THEORY. Robert L. Trimpi. March 1952. 72p. diagrs., photos. (NACA RM L52A18) (Declassified from Confidential, 4/14/55)

Experimental instantaneous pressure records of simulated ram-jet models without heat addition showed that they buzzed in a manner governed internally by quasi-one-dimensional (plane-wave) theory, a manner which is not compatible with the laws of the Helmholtz (spherical-wave) theory. A theory applicable to the buzzing problem was obtained through modification of the one-dimensional, unsteady-flow theory. Theoretical computations of the pressure-time curves agreed closely with the experimental records. A possible simulation of the buzzing in ram jets with combustion by the test of a cold-flow model in which a contraction in area replaces the combustion chamber is also discussed.

NACA RM L52B14

FLIGHT MEASUREMENTS OF THE LATERAL STABILITY AND CONTROL CHARACTERISTICS OF A HIGH-SPEED FIGHTER AIRPLANE. H. L. Crane, A. R. Beckhardt and C. E. Matheny. September 1952. 50p. diagrs., tab. (NACA RM L52B14) (Declassified from Confidential, 4/14/55)

Results are presented of measurements made of controls-free lateral oscillations, sideslips, rudder kicks, and aileron rolls at 10,000 at Mach numbers up to 0.815 and 30,000 feet at Mach numbers up to 0.84. The variations of the static derivatives obtainable from the sideslip data with Mach number are presented. Discussion of the controls-free lateral oscillations and of the tendency toward rudder snaking is included.

NACA RM L52D08

PRELIMINARY STUDY OF SOME FACTORS WHICH AFFECT THE STALL-FLUTTER CHARACTERISTICS OF THIN WINGS. A. Gerald Rainey. July 1952. 33p. diagrs., photo., tab. (NACA RM L52D08) (Declassified from Confidential, 4/14/55)

The results of an exploratory, analytical, and experimental study of some of the factors which might be of importance in the stall flutter of thin wings are presented. The factors considered were Mach number, Reynolds number, density, aspect ratio, sweepback, structural damping, location of torsion nodal line, and concentrated weights.

NACA RM L52D10

PRELIMINARY EXPERIMENTAL INVESTIGATION OF THE FLIGHT OF A PERSON SUPPORTED BY A JET THRUST DEVICE ATTACHED TO HIS FEET. C. H. Zimmerman, Paul R. Hill and T. L. Kennedy. January 1953. 31p. diagrs., photos., 2 tabs. (NACA RM L52D10) (Declassified from Confidential, 4/11/55)

An investigation has been made of the stability and controllability in space of an arrangement comprising a man standing on a small platform which is rigidly connected to a jet nozzle having its thrust opposed to the pull of gravity. A man can stand stably on a jet-supported platform with little or no practice. Factors which would be thought to be disturbing, such as gyroscopic couples, off-center weights, inertia of the platform, and unsteady wind velocity, had no objectionable effects. A high degree of maneuverability in translational flight within the confines of a limited space was demonstrated.

NACA RM L53G28

A THEORY FOR STABILITY AND BUZZ PULSATION AMPLITUDE IN RAM JETS AND AN EXPERIMENTAL INVESTIGATION INCLUDING SCALE EFFECTS. Robert L. Trimpi. October 1953. 75p. diagrs., photos., 3 tabs. (NACA RM L53G28) (Declassified from Confidential, 4/14/55)

From a theory developed on a quasi-one-dimensional-flow basis, it is found that the stability of the ram jet is dependent upon the instantaneous values of mass flow and total pressure recovery of the supersonic diffuser and immediate neighboring subsonic diffuser. Conditions for stable and unstable flow are presented. The theory developed in the paper is in agreement with the experimental data of the papers of both Sterbentz and Evvard and Ferri and Nucci. A simple theory for predicting the approximate amplitude of small pressure pulsation in terms of mass-flow decrement from minimum-stable mass flow is developed and found to agree with experiments. Cold-flow tests at a Mach number of 1.94 of ram-jet models having scale factors of 3.15:1 and Reynolds number ratios of 4.75:1 with several supersonic diffuser configurations showed only small variations in performance between geometrically similar models. The conditions at which buzz originated were nearly the same for the same supersonic diffuser (cowling-position angle) configurations in both large and small diameter models (both Reynolds numbers). There was no appreciable variation in stability limits of any of the models when the combustion-chamber length was increased by a factor of three. The unsteady-flow performance and wave patterns were also similar when considered on a reduced-frequency basis depending on the relative lengths of the model. The velocity profile in the combustion chamber at both Reynolds numbers was appreciably influenced by an angle of attack of $1/2^{\circ}$.

NACA RM L54B12a

FLIGHT TESTS OF A MAN STANDING ON A PLATFORM SUPPORTED BY A TEETERING ROTOR. Paul R. Hill and T. L. Kennedy. March 1954. 26p. diagrs., photos. (NACA RM L54B12a) (Declassified from Confidential, 4/11/55)

Following the lead given by successful flight tests of a man standing on a jet-supported platform, flight tests were made of a man standing on a teetering-rotor-supported platform. The rotor was 7 feet in diameter as was driven by compressed-air jets at the tips supplied to the machine by air hoses. Hovering and limited translational flights from 1- to 7-foot elevations were made both indoors and outdoors. The stability and controllability of the machine and flyer combination were satisfactory.

NACA RM L54G14a

A PRELIMINARY FLIGHT INVESTIGATION OF AN OIL-FLOW TECHNIQUE FOR AIR-FLOW VISUALIZATION. Harold I. Johnson and Robert G. Mungall. October 1954. 33p. diagrs., photos. (NACA RM L54G14a) (Declassified from Confidential, 4/14/55)

Preliminary experiments were made to evaluate a simple oil-flow technique for use in flight research. Photographs of oil flow on the wing of a swept-wing airplane in transonic flight and oil patterns remaining on the wing after flight at transonic speeds are presented. Also included are comparable shadowgraph and tuft pictures. The technique shows considerable promise, particularly for future transonic- and supersonic-flight research.

CURRENT NACA REPORTS

NACA Rept. 1173

ON TRAVELING WAVES IN BEAMS. Robert W. Leonard and Bernard Budiansky. 1954. iii, 27p. diagrs. (NACA Rept. 1173. Formerly TN 2874)

The basic equations of Timoshenko for the motion of vibrating nonuniform beams, which allow for effects of transverse shear deformation and rotary inertia, are presented in several forms; the propagation of sharp disturbances is discussed. Numerical traveling-wave solutions are obtained for some elementary problems of finite uniform beams for which the propagation velocities of shear and bending discontinuities are equal. Comparisons are made with modal solutions and, in some cases, with exact closed solutions.

NACA Rept. 1177

COMPARISON OF PERFORMANCE OF EXPERIMENTAL AND CONVENTIONAL CAGE DESIGNS AND MATERIALS FOR 75-MILLIMETER-BORE CYLINDRICAL ROLLER BEARINGS AT HIGH SPEEDS. William J. Anderson, E. Fred Macks and Zolton N. Nemeth. 1954. ii, 15p. diagrs., 6 tabs. (NACA Rept. 1177. Formerly TN 3001; TN 3002)

Studies are reported of four experimental bearings with outer-race-riding cages and inner-race-guided rollers operated at lower temperatures and to higher DN values (product of bearing bore in mm and shaft speed in rpm) than conventional inner- and outer-race-riding cage-type bearings. The experimental cages were designed to allow maximum cooling with minimum oil entrapment. In an investigation of four outer-race-riding cage-type bearings (two with bronze and two with nodular iron cages), heavy wear was found to accompany cage slip. Cage slip and, consequently, wear were found higher with nodular iron than with bronze at high speeds.

NACA Rept. 1185

THE CALCULATION OF PRESSURE ON SLENDER AIRPLANES IN SUBSONIC AND SUPERSONIC FLOW. Max. A. Heaslet and Harvard Lomax. 1954. ii. 11p. diagrs. (NACA Rept. 1185. Formerly TN 2900)

Under the assumption that a wing, body, or wing-body combination is slender or flying at near sonic velocity, expressions are given which permit the calculation of pressure in the immediate vicinity of the configuration. The disturbance field, in both subsonic and supersonic flight, is shown to consist of two-dimensional disturbance fields extending laterally and a longitudinal field that depends on the streamwise growth of cross-sectional area. A discussion is also given of couplings, between lifting and thickness effects, that necessarily arise as a result of the quadratic dependence of pressure on the induced velocity components.

NACA Rept. 1186

FORMATION AND COMBUSTION OF SMOKE IN LAMINAR FLAMES. Rose L. Schalla, Thomas P. Clark and Glen E. McDonald. 1954. ii, 21p. diagrs., photos. (NACA Rept. 1186. Formerly RM E51E15; RM E52G24; RM E52I22; RM E52I26; RM E53E05; RM E53J12; RM E54E03)

The nature and formation of smoke and its combustion were investigated. Factors affecting smoke formation were studied in both diffusion flames and premixed Bunsen flames. The variables investigated were (1) fuel type, (2) external air-flow rate, (3) oxygen-enrichment of external air, (4) substitution of argon for nitrogen in external oxidant, (5) fuel temperature or primary mixture temperature, and (6) pressure. The ability of a flame to burn smoke admitted from an exterior source was also studied. A critical survey was made of the literature pertaining to the mechanism of smoke formation.

NACA TN 3295

EFFECT OF PRESSURE ON THERMAL CONDUCTANCE OF CONTACT JOINTS. Martin E. Barzelay, Kin Nee Tong and George F. Holloway, Syracuse University. May 1955. 52p. diagrs., 2 tabs. (NACA TN 3295)

As an extension of previous experimental work further tests were conducted to determine the factors influencing the thermal conductance across the interface formed between stationary plane surfaces of 75S-T6 aluminum alloy and AISI Type 416 stainless-steel blocks. The types of joints investigated included bare metal-to-metal contact, contact surfaces separated by a good conductor (brass shim stock), and contact surfaces separated by a thin sheet of insulation (asbestos).

NACA TN 3297

EFFECT OF OXYGEN CONTENT OF FURNACE ATMOSPHERE ON ADHERENCE OF VITREOUS COATINGS TO IRON. A. G. Eubanks and D. G. Moore, National Bureau of Standards. May 1955. 17p. diagrs., photos., 2 tabs. (NACA TN 3297)

A series of vitreous coatings of the same basic composition, but with cobalt-oxide contents varying from 0 to 6.4 percent by weight, was fired on ingot iron in atmospheres consisting of various oxygen-nitrogen mixtures. The effect of the oxygen content of the atmosphere on adherence was determined by sub-

jecting each specimen to the American Society for Testing Materials adherence test, and the effect on interface roughness was estimated from examination of metallographic sections.

NACA TN 3381

HEAT-LOSS CHARACTERISTICS OF HOT-WIRE ANEMOMETERS AT VARIOUS DENSITIES IN TRANSONIC AND SUPERSONIC FLOW. W. G. Spangenberg, National Bureau of Standards. May 1955. 82p. diagrs., photos., 14 tabs. (NACA TN 3381)

An experimental investigation was made of the heat-loss characteristics of heated fine wires suitable for use as anemometers in turbulence research. Speeds ranged from low subsonic to Mach number 1.9. Density and temperature loading were varied over wide limits, and wire diameters ranged from 0.00005 to 0.0015 inch. The effects of each of the several variables on the heat-loss characteristics of both normally oriented and swept wires were measured.

NACA TN 3385

THEORY OF THE JET SYPHON. B. Szczeniowski, University of Montreal. May 1955. 49p. diagrs., 3 tabs. (NACA TN 3385)

A new approach to the theory of the mixing of two currents in an injector is presented, dealing with an incompressible ideal fluid. The theory shows new potentialities in an appropriate shaping of the form of the walls of the mixing zone so as to improve the jet-syphon efficiency beyond that heretofore predicted theoretically. Some examples of ways to improve jet-syphon efficiency are indicated.

NACA TN 3418

THE ZERO-LIFT WAVE DRAG OF A PARTICULAR FAMILY OF UNSWEPT, TAPERED WINGS WITH LINEARLY VARYING THICKNESS RATIO. Arthur Henderson, Jr. and Julia M. Goodwin. May 1955. 28p. diagrs. (NACA TN 3418)

On the basis of linear theory, the zero-lift wave drag of a particular family of unswept, tapered wings with linearly varying thickness ratio and symmetrical parabolic-arc sections has been calculated. By comparing the drag for these wings with that for a corresponding constant-thickness-ratio wing with rhombic sections, it is found that the variable-thickness-ratio wings can be used to advantage with no serious structural penalties if the wings are assumed to have the same given root thickness ratio or the same internal volume.

NACA TN 3436

AN INVESTIGATION OF SEVERAL NACA 1-SERIES NOSE INLETS WITH AND WITHOUT PROTRUDING CENTRAL BODIES AT HIGH-SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. Robert E. Pendley and Harold L. Robinson. May 1955. 51p. diagrs., photos. (NACA TN 3436. Formerly RM L9L23a)

Measurements of pressure distribution, drag, and internal-flow pressure loss are presented for three NACA 1-series nose inlets, two of which were fitted with protruded central bodies. Test Mach number and inlet-velocity ratio ranged from 0.4 to 1.2 and from 0 to 1.34, respectively. The nose-inlet pressure drag at a Mach number of 1.2 and the central-body effects on subcritical drag, the supercritical drag rise, and the inlet total-pressure loss are discussed.

NACA TN 3450

PRELIMINARY INVESTIGATION OF PROPERTIES OF HIGH-TEMPERATURE BRAZED JOINTS PROCESSED IN VACUUM OR IN MOLTEN SALT. C. A. Gyorgak and A. C. Francisco. May 1955. 29p. diagrs., photos., 7 tabs. (NACA TN 3450)

An investigation was conducted to determine the effect of the variables temperature, time at temperature, and nickel addition to the braze alloy on the shear strength of high-temperature-alloy brazed joints processed in vacuum or in molten salt. Both brazing methods produced shear strengths greater than those of joints processed in dry hydrogen. Vacuum brazing was superior to salt-bath brazing, average shear strengths being on the order of 63,000 and 48,000 psi, respectively.

NACA TN 3451

ANALYSIS OF FULLY DEVELOPED TURBULENT HEAT TRANSFER AND FLOW IN AN ANNULUS WITH VARIOUS ECCENTRICITIES. Robert G. Deissler and Maynard F. Taylor. May 1955. 42p. diagrs. (NACA TN 3451)

A previous analysis for turbulent heat transfer and flow in tubes was generalized and applied to an annulus with various eccentricities. Expressions for eddy diffusivity which were varified for flow and heat transfer in tubes were assumed to apply in general along lines normal to a wall. Velocity distributions, wall shear-stress distributions, and friction factors, as well as wall heat-transfer distributions, wall temperature distributions, and average heat-transfer coefficients, were calculated for an annulus having a radius ratio of 3.5 at various eccentricities.

NACA TN 3452

INVESTIGATION OF JET-ENGINE NOISE REDUCTION BY SCREENS LOCATED TRANSVERSELY ACROSS THE JET. Edmund E. Callaghan and Willard D. Coles. May 1955. 27p. diagrs., photos., tab. (NACA TN 3452)

An investigation of screens located transversely across a jet as a noise-reduction device was conducted on a full-scale turbojet engine. The screens lowered the sound pressure levels rearward and increased them in front resulting in a nearly circular, nondirectional sound field. The sound power level was lowered by as much as 7.5 db by the proper screen choice and location, and, in addition, the maximum sound pressure level was decreased approximately 12 db over that of the engine alone.

NACA TN 3453

LONGITUDINAL TURBULENT SPECTRUM SURVEY OF BOUNDARY LAYERS IN ADVERSE PRESSURE GRADIENTS. Virgil A. Sandborn and Raymond J. Slogar. May 1955. 40p. diagrs., tab. (NACA TN 3453)

Results of measurements of the longitudinal velocity-component spectra at various positions through the boundary layer for four stations in increasing adverse pressure gradients are presented in tabular form. A comparison is presented between longitudinal turbulence spectra in zero pressure gradient and in moderate adverse pressure gradients (reasonably far from separation). The effect of pressure gradient was found to be small. The measured spectra are also compared with the predicted variations derived from the hypothesis of statistical equilibrium. Longitudinal-turbulence scales and microscales evaluated from spectrum measurements are given.

Royal Aircraft Establishment (Gt. Brit.)
A STUDY OF THE LONGITUDINAL RESPONSE OF AIRCRAFT TO TURBULENT AIR. J. K. Zbrozek. January 1955. 31p. diagrs., tab. (RAE Aero 2530)

A method of calculating the aircraft dynamic behavior in turbulent air is presented. It is suggested that the assessment of the aircraft dynamic stability should include the study of aircraft behavior in turbulent air in addition to the present practice of evaluating the dynamic characteristics for perfectly smooth conditions. The dynamic behavior of aircraft in continuous turbulence is examined theoretically, investigating the influence of the following parameters: static margin (changing c.g. position), damping in pitch, lift slope, wing loading, and aircraft size. The theory outlined in the present paper provides the information required in gunnery and bombing problems and should be useful in the studies of automatic stabilization and gun- and bomb-sight design. Some results regarding gust loads in continuous turbulence are also obtained, which may have application in studies of the fatigue life of aircraft structures.

CALCULATED WEAK LIMIT FLAME TEMPERATURES OF HYDROCARBON-AIR-DILUENT MIXTURES. B. P. Mullins and J. M. Marley. March 1955. 20p. diagrs., 7 tabs. (NGTE Memo. M. 235)

Weak limit flame temperatures (T_L) have been calculated for hydrocarbon-air-diluent systems using the known experimental values of the ternary compositions at the weak limit of inflammability. The effectiveness of five gaseous diluents in causing T_L to increase lies in the ascending order: argon, nitrogen, water vapor, carbon dioxide, and carbon tetrachloride.

THE LOAD DISTRIBUTION AT SONIC SPEED OVER A FAMILY OF LINEARLY TWISTED WINGS WITH STRAIGHT-EDGED PLANFORMS. D. G. Randall. January 1955. 42p. diagrs., 3 tabs. (RAE Aero 2531)

The method for the calculation of the load distribution over a wing at sonic speed described by K. W. Mangler, which is based on linearized potential flow, is applied to a family of linearly twisted wings with straight-edged plan forms. The results obtained are plotted against the following three parameters: A the aspect ratio, $1 - \lambda/1 + \lambda$, where λ is the taper ratio, and A tan Λ 1/2, where Λ 1/2 is the sweepback angle of the half-chord line. The results obtained in previous work for the same family of plan forms at incidence are plotted against the same parameters. In addition a particular wing is studied in detail; chordwise pressure distributions, spanwise loading, etc. are presented for the plane wing at incidence and the twisted wing at zero incidence.

THE INTERACTION BETWEEN SHOCK WAVES AND BOUNDARY LAYERS. D. W. Holder, H. H. P Pearcey and G. E. Gadd. WITH A NOTE ON THE EFFECTS OF THE INTERACTION ON THE PERFORMANCE OF SUPERSONIC INTAKES. J. Seddon. 1955. 101p. diagrs., photos., 2 tabs. (ARC CP 180)

The interaction between shock waves and boundary layers has important effects in many problems of high-speed flow. This paper has been written as a guide to the literature on the subject, and as a critical review of the present state of knowledge concerning both the underlying physical processes and the practical applications. Part I of the paper describes experiments on comparatively simple types of flow designed to provide fundamental information and to assist in the development of the theory. Many of the features found in the fundamental experiments appear also in practical applications and these are considered in Parts II and III. Some notes on the further work that is required are given in Part IV.

SHADOWGRAPHS OF MODEL PROJECTILES FIRED AT HIGH MACH NUMBERS AND NEAR M = 1 IN THE N. P. L. BALLISTIC RANGE. W. F. Cope. 1955. 49p. diagrs., photos. (ARC CP 189)

Shadowgraphs of 20 mm projectiles fired at Mach numbers above 3 are shown and the important features are discussed. Shadowgraphs of three rounds which passed through M = 1 are also shown. In all three cases the drag coefficient was determined, and for one, all of the aerodynamic coefficients were found. The effect of the retardation is discussed and it is concluded that the effect is probably small enough to be negligible except perhaps on the drag. These rounds were stable. The unstable region for a projectile is at a lower Mach number (about 0.75). To illustrate this, the analysis of some earlier rounds is included.

NOTE ON THE FLOW NEAR THE TAIL OF A TWO-DIMENSIONAL AEROFOIL MOVING AT A FREE-STREAM MACH NUMBER CLOSE TO UNITY. D. W. Holder. 1955. 11p. diagrs., photos. (ARC CP 188)

A qualitative argument, which is supported by experimental evidence, suggests that the local Mach number downstream of the trailing-edge shock waves is approximately independent of free-stream Mach number, airfoil geometry, and angle of attack. Thus, there is a unique relationship between the flow deflection angle at the trailing edge and the local Mach number just upstream of the trailing-edge shock waves. This relationship is determined from wind-tunnel experiments on RAE series airfoils and may be used to give rapid estimates of the local Mach number at the trailing-edge of an airfoil in terms of the trailing-edge angle, angle of attack, and control angle. The characteristics of straight-sided controls are considered for an example.

INTEGRATION OF THE BOUNDARY LAYER EQUATIONS FOR A PLANE IN COMPRESSIBLE FLOW BY THE METHOD OF STEEPEST DESCENT. D. Meksyn. July 31, 1954. 11p. tab. (ARC 16,961; FM 2098)

In a former paper the author found the asymptotic integrals of the equations of motion for the flow past a semi-infinite plane for supersonic speed, for the case when the coefficients of viscosity and conductivity depend on or are independent of temperature, and has shown that the results obtained are in close agreement with those found by numerical integration. The integration was carried out for the case of no heat transfer and for a particular value of Prandtl number $\sigma = 0.733$. The aim of the present paper is to extend the integration of the equations to the general case of heat transfer and arbitrary σ (close to unity).

SURFACE NOISE FROM A PLANE TURBULENT BOUNDARY LAYER. O. M. Phillips. August 4, 1954. 15p. diagr. (ARC 16,963; FM 2099)

A study is made of the properties of the viscous sublayer in a turbulent flow past a solid boundary, from which the surface noise produced by the distribution of fluctuating stresses on a plane boundary can be estimated. The intensity of the surface noise per unit area is compared with the expression given by Lighthill for the aerodynamic quadrupole noise of a turbulent boundary layer. It appears that for Mach numbers less than about unity, the dipole radiation from the surface is more efficient than the quadrupole radiation from the turbulent boundary layer itself.

Aeronautical Research Council (Gt. Brit.)
THE DISTRIBUTION OF PRESSURE ON AN AEROFOIL, IN A STREAM WITH A SPANWISE VELOCITY GRADIENT. W. A. Mair. July 13, 1954. 16p. diagrs., 3 tabs. (ARC 16,937; FM 2093)

Pressure measurements were made at one section of an airfoil of constant chord spanning a wind tunnel. A flat plate was mounted in the tunnel upstream of the airfoil so that the wake from the plate produced a spanwise velocity gradient at the airfoil. By traversing the plate across the tunnel, the position of the wake could be altered relative to the pressure holes in the airfoil so that the complete pressure distribution over the airfoil in the neighborhood of the wake could be found. The results showed that, because of the secondary flow produced by the interaction between the airfoil and the wake, the variation of the pressure across the wake for a given chordwise position was very small, except close to the leading edge. The lift coefficient was nearly constant across the wake. The form drag coefficient was considerably reduced in the wake.

Aeronautical Research Council (Gt. Brit.)
ON THE EFFECT OF WING BENDING ON THE ACCELERATION DUE TO LANDING IMPACT. A. R. Collar. June 1954. 6p. diagrs. (ARC 16,960; S. 729)

Some previously recorded measurements of the normal accelerations due to landing of a seaplane at varying vertical velocities are compared with accelerations theoretically predicted. While good

agreement is obtained on the magnitude of the peak acceleration, this peak occurs in all cases about twice as long after impact as is predicted by theory. Various explanations have been considered, including that of wing bending; however, this had been discarded. The present author believes that the flexibility of the structure might cushion the impact. Since all the vertical momentum must be destroyed, whether the wings are flexible or not, it is to be expected that the peak acceleration will be about the same, but it will occur later if the wings flex than if they are rigid. A simple mathematical model is discussed.

Ministry of Supply (Gt. Brit.)
EXPERIENCE OF FATIGUE AT WEYBRIDGE. Part 2: - AN INVESTIGATION INTO THE FATIGUE STRENGTH OF ALUMINIUM ALLOY TO SPECIFICATION. D. T. D. 364. (Part 2 of final report prepared by Vickers-Armstrong, Ltd., Weybridge) March 1955. iii, 31p. diagrs., 15 tabs. (Ministry of Supply. S & TM 2/55)

This report presents the results of a series of direct stress fatigue tests on aluminum alloy D. T. D. 364 (2014). The work described in this report shows clearly the difficulty of establishing for a given material allowable fatigue stresses on simple specimens. It is considered that much more work is necessary on other light alloy specifications, and that more work should be undertaken to establish precisely the calibration of fatigue testing machines.

Royal Aircraft Establishment (Gt. Brit.)
SOME PROPELLER NOISE CALCULATIONS SHOWING THE EFFECT OF THICKNESS AND PLANFORM. K. V. Diprose. January 1955. 16p. diagrs., 4 tabs. (RAE Tech. Note MS 19)

Sound pressures have been calculated for a propeller designed for a high-speed airplane (Mach 0.77). The contribution to the noise due to the blade thickness was much larger than expected; reasons are given for doubting the validity of the formulas used, and ways of improving them suggested. Tapering the plan form, to move the main sources of noise further inboard to regions of lower Mach number was found to produce only small relief in the calculated noise.

N-36641*

Royal Aircraft Establishment (Gt. Brit.)
WIND TUNNEL OBSERVATIONS OF BOUNDARY LAYER TRANSITION ON TWO SWEPTBACK WINGS AT A MACH NUMBER OF 1.61. J. B. Scott-Wilson and D. S. Capps. December 1954. 12p. diagrs., photos. (RAE Tech. Note Aero 2347)

Visual observations of transition were made on two sweptback wings at a Mach number of 1.61. Laminar boundary-layer instability which resulted in the formation of streamwise vortices, was found on these wings. At zero incidence the Reynolds number, based on the mean chord of the wing, at which this instability occurred, 1.9×10^6, was very much lower than the critical value predicted by low-speed theory. At incidence the laminar boundary layer on the wing was found to be more stable on the upper surface, but less stable on the lower surface than at zero incidence.

N-36642*

Royal Aircraft Establishment (Gt. Brit.)
THE MECHANISM OF FATIGUE FAILURE IN SOME BINARY AND TERNARY ALUMINIUM ALLOYS. P. J. E. Forsyth and C. A. Stubbington. December 1954. 27p. diagrs., photos., tab. (RAE Met. 81)

The fatigue process in a number of aluminum alloys was found to be one of depletion of solute atoms in localized regions under the action of cyclic stresses. This depletion or overageing provided soft spots in the structure in which most of the subsequent plastic deformation was concentrated. Depending on temperature, these depleted zones were trans or intercrystalline, and the subsequent fatigue crack followed these paths. A crack once started, might, by virtue of the heavy stress concentration, produce its own depleted zone ahead of the root, and could thus progress without particular reference to existing soft spots.

DECLASSIFIED NACA REPORTS

NACA RM A51E16

A FLIGHT STUDY OF REQUIREMENTS FOR SATISFACTORY LATERAL OSCILLATORY CHARACTERISTICS OF FIGHTER AIRCRAFT. Charles J. Liddell, Jr., Brent Y. Creer and Rudolph D. Van Dyke, Jr. July 1951. 39p. diagrs., photo., 2 tabs. (NACA RM A51E16) (Declassified from Confidential, 5/10/55)

A conventional, propeller-driven fighter, fitted with servo devices for varying in flight the dihedral effect, the static directional stability, and the directional damping was used in a pilot-opinion survey to determine the lateral-oscillatory characteristics which go to make up satisfactory lateral flying qualities. In addition, the lateral aperiodic motions encountered during the investigation and their relations to the pilots' opinions are discussed.

NACA RM E52E16

EXPERIMENTAL INVESTIGATION OF AIR-FLOW UNIFORMITY AND PRESSURE LEVEL ON WIRE CLOTH FOR TRANSPIRATION-COOLING APPLICATIONS. Patrick L. Donoughe and Roy A. McKinnon. July 1952. 28p. diagrs., photos., tab. (NACA RM E52E16) (Declassified from Confidential, 5/10/55)

An experimental investigation was conducted to obtain information on air-flow uniformity and pressure-level effects for various meshes of stainless-steel corduroy wire cloth, and permeability and strength data for a 20- by 20-mesh stainless-steel wire cloth. It was found that close control of the wire cloth thickness yielded sufficiently uniform air flow and that available methods may be used to predict the effect of pressure level. Permeability and strengths of the 20- by 20-mesh wire cloth were similar to those already available from other meshes. The reduced tensile strength of the 20- by 20-mesh wire cloth in the direction of the primary stresses is one and a half to three times as great as the strength of the best porous sintered materials presently available.

NACA RM L52E07

AN INVESTIGATION OF THE LOW-SPEED LONGITUDINAL STABILITY CHARACTERISTICS OF A SWEPT-WING AIRPLANE MODEL WITH TWO MODIFICATIONS TO THE WING-ROOT PLAN FORM. William B. Kemp, Jr. July 1952. 17p. diagrs., tab. (NACA RM L52E07) (Declassified from Confidential, 5/10/55)

An investigation has been conducted in the Langley 300-mph 7- by 10-foot tunnel to determine the effects of two wing-root leading-edge plan-form modifications on the low-speed longitudinal stability characteristics of a complete airplane model having a 50.7° sweptback wing.

NACA RM L53E11

EFFECTS OF RATE OF FLAP DEFLECTION ON FLAP HINGE MOMENT AND WING LIFT THROUGH THE MACH NUMBER RANGE FROM 0.32 TO 0.87. Thomas R. Turner. June 1953. 29p. diagrs., photos. (NACA RM L53E11) (Declassified from Confidential, 5/10/55)

An investigation at Mach numbers from 0.32 to 0.87 has been made to determine the effect of rate of flap deflection on flap hinge moment and wing lift. Rate of flap deflection varied from 0° to 1.17^{o} per chord length of travel. The Reynolds number varied from approximately 1.0 to 2.3 x 10^{6}. The wing had an aspect ratio of 4, a taper ratio of 0.6, and zero sweep of the 75-percent-chord line. The wing was fitted with a full-span 25-percent-chord plain flap.

NACA RM L53E15

SOME OBSERVATIONS ON STALL FLUTTER AND BUFFETING. A. Gerald Rainey. June 1953. 11p. diagrs. (NACA RM L53E15) (Declassified from Confidential, 5/10/55)

An attempt is made to describe the phenomenological differences between stall flutter and buffeting. Some experimental results are presented concerning both the boundaries at which these phenomena occur and the stresses involved.

CURRENT NACA REPORTS

NACA Rept. 1182

COMPARISON OF EFFECTIVENESS OF CONVECTION-, TRANSPIRATION-, AND FILM-COOLING METHODS WITH AIR AS COOLANT. E. R. G. Eckert and John N. B. Livingood. 1954. ii, 17p. diagrs. (NACA Rept. 1182. Formerly TN 3010)

Material necessary for a comparison of the cooling requirements of film and transpiration cooling with conventional convection cooling is presented. Both laminar and turbulent flow, with and without radiation, are considered for a flat plate. The superiority of transpiration cooling is clearly shown for both laminar and turbulent flow.

NACA RM L55D15a

SOME OBSERVATIONS ON LOSS OF STATIC STRENGTH DUE TO FATIGUE CRACKS. Walter Illg and Herbert F. Hardrath. May 1955. 8p. diagrs. (NACA RM L55D15a)

Static tensile tests were performed on simple notched specimens containing fatigue cracks. Four types of aluminum alloys were investigated: 2024-T3 (formerly 24S-T3) and 7075-T6 (formerly 75S-T6) in sheet form, and 2024-T4 (formerly 24S-T4) and 7075-T6 (formerly 75S-T6) in extruded form. The cracked specimens were tested statically under four conditions: unmodified and with reduced eccentricity of loading by three methods. Results of static tests on C-46 wings containing fatigue cracks are also reported.

NACA RM L55D15b

PRELIMINARY INVESTIGATION OF THE FAILURE OF PRESSURIZED STIFFENED CYLINDERS. Norris F. Dow and Roger W. Peters. May 1955. 14p. diagrs., photos., tab. (NACA RM L55D15b)

Tests were made of stiffened cylinders of 2024 aluminum alloy under internal pressure and cyclic torsion. Both gradual and explosive types of failures occurred. The type of failure depended upon the hoop stress and structural configuration, particularly on the ratio of area in rings to associated skin area.

NACA TM 1379

A METHOD OF QUADRATURE FOR CALCULATION OF THE LAMINAR AND TURBULENT BOUNDARY LAYER IN CASE OF PLANE AND ROTATIONALLY SYMMETRICAL FLOW. (Ein Quadraturverfahren zur Berechnung der laminaren und turbulenten Reibungsschicht bei ebener und rotationssymmetrischer Strömung). E. Truckenbrodt. May 1955. 40p. diagrs. (NACA TM 1379. Trans. from Ingenieur-Archiv, v. 20, no. 4, 1952, p. 16-228).

For calculation of the characteristic parameters of the boundary layer (momentum-loss thickness and form parameter for the velocity profile), two quadrature formulas are given which are valid for the laminar as well as for the turbulent state of flow. These formulas cover both the two-dimensional and the rotationally symmetrical case. The calculation of the momentum-loss thickness is carried out by a simple integration of the energy theorem. The equation for the form parameter is obtained by coupling of the momentum theorem with the energy theorem. Knowledge of the derivatives of the velocity distribution and of the radius of the body along the length x is not necessary.

NACA TN 3296

SEPARATION, STABILITY, AND OTHER PROPERTIES OF COMPRESSIBLE LAMINAR BOUNDARY LAYER WITH PRESSURE GRADIENT AND HEAT TRANSFER. Morris Morduchow and Richard G. Grape, Polytechnic Institute of Brooklyn. May 1955. 45p. diagrs., 6 tabs. (NACA TN 3296)

A theoretical study is made of the effect of pressure gradient, wall temperature, and Mach number on laminar boundary-layer characteristics and, in particular, on the skin-friction and heat-transfer coefficients, on the separation point in an adverse pressure gradient, on the wall temperature required for complete stabilization of the laminar boundary layer, and on the minimum critical Reynolds number for laminar stability. A simple and accurate method of locating the separation point in a compressible flow with heat transfer is developed.

NACA TN 3314

A TECHNIQUE UTILIZING ROCKET-PROPELLED TEST VEHICLES FOR THE MEASUREMENT OF THE DAMPING IN ROLL OF STING-MOUNTED MODELS AND SOME INITIAL RESULTS FOR DELTA AND UNSWEPT TAPERED WINGS. William M. Bland, Jr. and Carl A. Sandahl. May 1955. 25p. diagrs., photos., tab. (NACA TN 3314. Formerly RM L50D24)

* AVAILABLE ON LOAN ONLY.
ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

A free-flight test technique with which the damping in roll of sting-mounted models can be measured over the high subsonic, transonic, and supersonic speed range with rocket-propelled test vehicles is described. Initial results for delta and unswept tapered wings are presented and compared with theory.

NACA TN 3367

A DYNAMIC-MODEL STUDY OF THE EFFECT OF ADDED WEIGHTS AND OTHER STRUCTURAL VARIATIONS ON THE BLADE BENDING STRAINS OF AN EXPERIMENTAL TWO-BLADE JET-DRIVEN HELICOPTER IN HOVERING AND FORWARD FLIGHT. John Locke McCarty and George W. Brooks. May 1955. i. 47p. diagrs., photo., 6 tabs. (NACA TN 3367)

An experimental investigation of the rotor system of a 1/10-scale dynamic model of an experimental two-blade jet-driven helicopter to determine the effect of various changes in the design configuration on the blade bending strains has been conducted. These changes included the addition of different amounts of concentrated weight to the blades at various radial and chordwise locations and variations in the design counterweight locations, as well as changes in the blade-pitch-control stiffness. The blade bending strains could be materially reduced by adding concentrated weights to the blades in such a manner as to minimize resonance conditions or to induce favorable coupling of blade bending and torsion deformations.

NACA TN 3394

LOW-SPEED INVESTIGATION OF THE EFFECTS OF ANGLE OF ATTACK ON THE PRESSURE RECOVERY OF A CIRCULAR NOSE INLET WITH SEVERAL LIP SHAPES. James R. Blackaby. May 1955. 30p. diagrs., photo. (NACA TN 3394)

An investigation was made at a free-stream Mach number of 0.237 of the effects of lip bluntness and profile on the total-pressure recovery of a circular nose inlet in a ducted body of revolution at angles of attack up to 25°. A sharp inlet lip having a wedge angle of $7\text{-}1/2^{\circ}$ was tested in addition to two circular-arc lips and two lips with elliptical profiles, all of which were formed within the $7\text{-}1/2^{\circ}$ angle of the sharp lip.

NACA TN 3395

ON THE CALCULATION OF THE 1·P OSCILLATING AERODYNAMIC LOADS ON SINGLE-ROTATION PROPELLERS IN PITCH ON TRACTOR AIRPLANES. Vernon L. Rogallo and Paul F. Yaggy. May 1955. 28p. diagrs., photo. (NACA TN 3395)

A procedure for calculating the 1·P oscillating aerodynamic thrust loads on single-rotation, tractor propellers in pitch at zero yaw is developed and is evaluated. Application of the procedure requires knowledge of only the upflow angles at the horizontal center line of the propeller disk. The applicability of the procedure to various airplane configurations is discussed.

NACA TN 3417

MEASUREMENTS OF FREE-SPACE OSCILLATING PRESSURES NEAR A PROPELLER AT FLIGHT MACH NUMBERS TO 0.72. Arthur W. Vogeley and Max C. Kurbjun. May 1955. 24p. diagrs., photos., tab. (NACA TN 3417)

Limited measurements have been made of the free-space oscillatory pressures near the tips of a propeller at flight Mach numbers up to 0.72. Measurements were made at a single radial station and at three axial positions (ahead of, in the plane of, and behind the propeller disk). Comparisons, showing the effects of forward Mach number on oscillating pressures, are made with the Garrick-Watkins theory (NACA TN 3018).

NACA TN 3424

AERODYNAMIC CHARACTERISTICS OF SEVERAL 6-PERCENT-THICK AIRFOILS AT ANGLES OF ATTACK FROM 0° TO 20° AT HIGH SUBSONIC SPEEDS. Bernard N. Daley and Douglas R. Lord. May 1955. 57p. diagrs., photos. (NACA TN 3424. Formerly RM L9E19)

Aerodynamic characteristics obtained from two-dimensional tests of eight 6-percent-thick symmetrical airfoils of the supersonic and subsonic type are presented at angles of attack from 0° to 20° and at Mach numbers from 0.3 to about 0.9. Results indicate generally improved characteristics for the circular-arc and wedge-type airfoils when the maximum thickness was located forward. The variations with Mach number of the lift, drag, and pitching-moment coefficients are generally similar for those supersonic- and subsonic-type airfoils tested.

NACA TN 3425

SOME CALCULATIONS OF THE LATERAL RESPONSE OF TWO AIRPLANES TO ATMOSPHERIC TURBULENCE WITH RELATION TO THE LATERAL SNAKING PROBLEM. John D. Bird. May 1955. 24p. diagrs., 2 tabs. (NACA TN 3425. Formerly RM L50F26a)

Results of calculations of the lateral response to representative time histories of atmospheric turbulence for two airplanes having widely different dynamic properties indicate that, under the proper conditions, atmospheric turbulence can initiate and maintain a lateral hunting oscillation of an airplane, and that this oscillation can be fairly regular in both amplitude and frequency. This effect is more pronounced for lightly damped airplanes.

NACA TN 3427

THEORETICAL INVESTIGATION OF A PROPORTIONAL-PLUS-FLICKER AUTOMATIC PILOT. Ernest C. Seaberg. May 1955. 53p. diagrs., photo., tab. (NACA TN 3427. Formerly RM L50I19)

An analysis has been made of the stability of a supersonic canard airframe and a proportional-plus-flicker autopilot. Essentially, this autopilot maintains a zero reference about which the output is proportional to the input and a flicker response overrides this proportional response at a fixed angle of gimbal displacement on either side of the zero gyroscope reference. The analysis consists of an investigation of the calculated transient responses based on the variation of the autopilot and aerodynamic parameters. The calculations are based on the assumption that the proportional part of the system either contains a perfect autopilot or is the actual autopilot frequency response approximated by mathematical transfer function.

NACA TN 3433

TOTAL LIFT AND PITCHING MOMENT ON THIN ARROWHEAD WINGS OSCILLATING IN SUPERSONIC POTENTIAL FLOW. H. J. Cunningham. May 1955. 43p. diagrs., 4 tabs. (NACA TN 3433)

Total lift and moment coefficients are given for thin arrowhead wings oscillating in pitch and vertical translation which extend to the fifth power and to the third power of the frequency for the subsonic- and supersonic-leading-edge cases, respectively. These expressions are sufficiently accurate to make them potentially useful in flutter applications.

NACA TN 3438

ON THE KERNEL FUNCTION OF THE INTEGRAL EQUATION RELATING LIFT AND DOWNWASH DISTRIBUTIONS OF OSCILLATING WINGS IN SUPERSONIC FLOW. Charles E. Watkins and Julian H. Berman. May 1955. 43p. (NACA TN 3438)

A suitable form of doublet potential that serves as a basis for deriving the kernel function for supersonic flow, corresponding to the kernel function for subsonic flow presented in NACA TN 3131, is derived by using a cutoff or unit function. A treatment similar to that made for the subsonic kernel is made for the kernel function for supersonic flow. The singularities are isolated and discussed, and the kernel function is shown to lead to correct results for two-dimensional flow, and to reduce properly to the sonic case.

NACA TN 3439

ANALYSIS OF EAR FORMATION IN DEEP-DRAWN CUPS. Arthur J. McEvily, Jr. May 1955. 7p. diagrs. (NACA TN 3439)

A review of the literature on deep drawing and on anisotropy of metals indicates that no direct correlation has been established between the number and location of the ears on deep-drawn cups and the preferred crystallographic orientation of the blank material. In the present paper, a method for predicting earing behavior is proposed which is based on the plastic properties of single crystals and a knowledge of the preferred orientation of the blank material. The proposed method of prediction is in satisfactory agreement with reported experimental results.

NACA TN 3440

HOVERING FLIGHT TESTS OF A FOUR-ENGINE-TRANSPORT VERTICAL TAKE-OFF AIRPLANE MODEL UTILIZING A LARGE FLAP AND EXTENSIBLE VANES FOR REDIRECTING THE PROPELLER SLIPSTREAM. Louis P. Tosti and Edwin E. Davenport. May 1955. 26p. diagrs., photos., tab. (NACA TN 3440)

An investigation of the take-off, landing, and hovering flight characteristics of a four-engine-transport, vertical take-off airplane has been conducted with a remotely controlled free-flight model. The model had four propellers distributed along the wing with thrust axes parallel to the fuselage axis. In order to produce direct lift for hovering flight the propeller slipstream was deflected downward about 70° by a full-span 65-percent-chord flap deflected 90° and eight extensible vanes arranged above the wing in a cascade relation.

NACA TN 3441

AN NACA VANE-TYPE ANGLE-OF-ATTACK INDICATOR FOR USE AT SUBSONIC AND SUPERSONIC SPEEDS. Jesse L. Mitchell and Robert F. Peck. May 1955. 8p. diagrs., photo. (NACA TN 3441. Formerly RM L9F28a)

A description is presented of a vane-type angle-of-attack indicator developed by the NACA for use at supersonic and subsonic speeds. A brief history of the development and a wind-tunnel calibration are given together with a discussion of the corrections to be applied to the indicated readings.

NACA TN 3442

A PRELIMINARY INVESTIGATION OF AERODYNAMIC CHARACTERISTICS OF SMALL INCLINED AIR OUTLETS AT TRANSONIC MACH NUMBERS. Paul E. Dewey. May 1955. 21p. diagrs., photos. (NACA TN 3442. Formerly RM L53C10)

The aerodynamic characteristics of several outlets with inclined or curved axes discharging air into a transonic stream have been investigated. The data presented herein show the discharge coefficient of such outlets and the static-pressure distribution in the vicinity of the outlets for several values of stream Mach number and discharge flow parameter. Tuft observations, showing the vortex formation caused by the outlet discharge from a perpendicular and an inclined outlet, are also presented.

NACA TN 3444

FRICTION, WEAR, AND SURFACE DAMAGE OF METALS AS AFFECTED BY SOLID SURFACE FILMS. Edmond E. Bisson, Robert L. Johnson, Max A. Swikert and Douglas Godfrey. May 1955. 60p. diagrs., photos., tab. (NACA TN 3444)

A summation is presented of NACA results obtained from friction and wear investigations from 1946 to 1954. The results are consistent with theoretical predictions that solid surface films of low shear strength can serve to reduce both friction and surface damage. Metallic oxides can have very marked effects. Wear studies show that the ability of materials to form surface films is an important factor in wear. Solid lubricants (MoS_2 and graphite) are beneficial under severe operating conditions, including temperatures approaching 1000° F; both materials are, however, subject to oxidation at these temperatures.

NACA TN 3454

EFFECT OF A DISCONTINUITY ON TURBULENT BOUNDARY-LAYER-THICKNESS PARAMETERS WITH APPLICATION TO SHOCK-INDUCED SEPARATION. Eli Reshotko and Maurice Tucker. May 1955. 21p. diagrs. (NACA TN 3454)

The problem of shock-induced turbulent boundary-layer separation was analyzed by an approximate method. This method is based on a moment-of-momentum equation and calculates the change of boundary-layer-thickness parameters and form factor caused by a discontinuity where effects of friction can be neglected. The form of the result suggests that the Mach number ratio across the shock is a characteristic parameter for defining shock-induced separation. The method is also used to estimate the effects of mass transfer on the boundary-layer-thickness parameters for zero pressure gradient.

Royal Aircraft Establishment (Gt. Brit.)
THE USE OF QUARTZ IN THE MANUFACTURE OF SMALL DIAMETER PITOT TUBES. J. R. Cooke. December 1954. 15p. diagrs., photos., tab. (RAE Tech. Note Aero 2325)

This note describes the method of manufacture of small quartz-tipped pitot tubes (down to 0.005 in. outside tip diameter) which have been used successfully for boundary-layer measurements on small models in a supersonic wind tunnel. Tests have been made (a) of the effects of taper and end finish on the accuracy of measurement and (b) of the effect of the inside diameter of the tip (for a standard taper) on response rate. For a given inside tip diameter, the tapered quartz tubes gave a faster response rate than the stainless steel hypodermic tubes previously used.

Aeronautical Research Council (Gt. Brit.)
TESTS RELATED TO THE EFFECT OF PROFILE SHAPE AND CAMBER-LINE ON COMPRESSOR CASCADE PERFORMANCE. S. J. Andrews. 1955. 23p. diagrs. (ARC R & M 2743; ARC 13,207. Formerly NGTE R. 60)

Three shapes were chosen for comparison with the airfoil. They were the flat plate with rounded leading and trailing edges, a flat plate with sharpened leading and trailing edges, and an approximately biconvex shape. A representative cascade shape was chosen and four cascades with the four sections mounted on circular-arc camber lines were made up. In addition, two cascades were made up on parabolic arcs. The main conclusions are that the approximately biconvex profile is superior to the airfoil at Mach numbers above 0.75, and that the circular arc camber line is, on the whole, superior to the parabolic arc. The "plate" blades with blunt leading and trailing edges are poor in performance, but the "plate with sharpened edges" is reasonably good.

N-36850*

Aeronautical Research Council (Gt. Brit.)
AERODYNAMIC FORCES ON RECTANGULAR WINGS OSCILLATING IN A SUPERSONIC AIR STREAM. W. E. A. Acum. 1954. 28p. diagrs., 2 tabs. (ARC R & M 2763. Formerly ARC 13,286; FM 1465; 0.879; S & C 2418)

In this report linearized theory is used and numerical solutions are derived by the method of "relaxation." The problem reduces to one of finding a series of conical flow solutions. Moment coefficients for a range of Mach numbers and various frequency parameter values were calculated. For a range of Mach numbers in two-dimensional flow, the aerodynamic damping for pitching oscillation can be negative for certain positions of the axis of pitch oscillation, and this implies instability. The results of this report show that aspect ratio has a stabilizing effect for axes less than about 0.7 of the chord downstream of the leading edge, but has the opposite effect for axes nearer than this to the trailing edge.

N-36851*

Aeronautical Research Council (Gt. Brit.)
THE SECONDARY FLOW IN CURVED PIPES. H. G. Cuming. 1955. 17p. diagrs., 3 tabs. (ARC R & M 2880. Formerly ARC 13,979; FM 1558)

The Navier-Stokes equations for the flow of a viscous incompressible fluid through curved pipes of different sections are solved in power series of the curvature of the pipe. The solution is given as far as the first power of the curvature for the case of an elliptic section and a discussion given of the effect of the aspect ratio of the pipe on the intensity of the secondary flow. The solution is also given to the first power of the curvature for the case of a square section and as far as the second power of the curvature for the case of flow through a curved pipe of circular section when suction proportional to the curvature is applied at the walls. The result shows that with the particular distribution of suction considered the diminution in flux through a curved pipe may be almost entirely eliminated.

Forest Products Research Lab. (Gt. Brit.)
TRIALS OF TIMBER FOR PLYWOOD MANUFACTURE. ADWEA - PACHYLOBUS BARTERI - GOLD COAST. (48 POUNDS PER CUBIC FOOT AT 15 PER CENT MOISTURE CONTENT) APPENDIX B: STRENGTH TESTS ON ADWEA PLYWOOD. W. T. Curry. APPENDIX C: TESTS DESIGNED TO COMPARE THE LIMITING RADIUS OF CURVATURE IN THE BENDING OF ADWEA (PACHYLOBUS BARTERI) 3-PLY WITH THOSE OF CANADIAN YELLOW BIRCH (BETULA LUTEA). N. Turner. (PROGRESS REPORT TWENTY-FIVE) January 1955. 21p. 6 tabs. (Forest Products Research Lab.)

Earlier tests had indicated that Adwea plywood possessed strength properties similar to those of Canadian birch. It was agreed by the Plywood Research Panel that tests to confirm this were most desirable, and that at the same time, an assessment should be made of the potentialities of the species for general plywood manufacture. Results of these tests and some comparisons with Canadian yellow birch are presented in this report.

UNPUBLISHED PAPERS

HELICAL VORTICES AND CYLINDRICAL BOUNDARIES OF CIRCULAR CROSS SECTION. (Rasen uzu to Ento Kyokai). Hisawo Takeyama. 8p. (Trans. from Oyo Rigaku, v. 3, no. 13, Aug., 1949, p. 6-8)

The velocity potential of helical vortices in the cylindrical boundaries, whose cross sections are circles coaxial with the vortices, is obtained in order to estimate the tip losses and body interference for axial blowers or propellers. In the case of the fixed boundary, the circulation is increased near the tip; but for the free boundary, it is decreased. It is also shown that the inner and outer boundaries can be treated separately in the usual blowers.

CURRENT NACA REPORTS

NACA Rept. 1187

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF ADDITIVE DRAG. Merwin Sibulkin. 1954. ii, 12p. diagrs. (NACA Rept. 1187. Formerly RM E51B13)

The significance of additive drag is discussed and equations for determining its approximate value are derived. Charts are presented giving values of additive drag for open-nose inlets and for annular-nose inlets with conical flow at the inlet. The effects of variable inlet total-pressure recovery and static pressures on the center body are investigated, and an analytical method of predicting the variation of pressure on the center body with mass-flow ratio is given. Experimental values of additive drag are compared with values predicted by the methods presented.

NACA RM L55E09a

SUMMARY OF RECENT THEORETICAL AND EXPERIMENTAL WORK ON BOX-BEAM VIBRATIONS. John M. Hedgepeth. June 1955. 10p. diagrs., photo., 2 tabs. (NACA RM L55E09a)

A discussion of various secondary effects which have an important influence on the vibration characteristics of box beams is presented. Means of incorporating these effects in vibration analyses of actual built-up box beams are discussed. Comparisons with experiment are given; good agreement between theory and experiment is obtained when the secondary effects are included.

NACA RM L55E11b

PRELIMINARY INVESTIGATION OF THE COMPRESSIVE STRENGTH AND CREEP LIFETIME OF 2024-T3 (FORMERLY 24S-T3) ALUMINUM-ALLOY PLATES AT ELEVATED TEMPERATURES. Eldon E. Mathauser and William D. Deveikis. June 1955. 12p. diagrs. (NACA RM L55E11b)

The results of elevated-temperature compressive strength and creep tests of 2024-T3 (formerly 24S-T3) aluminum-alloy plates supported in V-grooves are presented. A relation previously developed for predicting plate compressive strength at room temperature was satisfactory for determining elevated temperature strength. Creep-lifetime results are presented for the plates in the form of master creep-lifetime curves using a time temperature parameter. A comparison is made between tensile and compressive creep lifetime for the plates, and the magnitude by which the design stress is decreased because of material creep and loss of strength due to exposure at elevated temperatures is indicated.

NACA RM L55E12b

TENSILE PROPERTIES OF SOME SHEET MATERIALS UNDER RAPID-HEATING CONDITIONS. George J. Heimerl and John E. Inge. June 1955. 10p. diagrs. (NACA RM L55E12b)

Results are presented of tests to determine the effect of heating at uniform temperature rates from 0.2° F to 100° F per second on the tensile properties of some sheet materials under constant load conditions - 7075-T6 (75S-T6) and 2024-T3 (24S-T3) aluminum alloys, Inconel, and RS-120 titanium alloy. Some comparisons are given between yield and rupture stresses obtained under rapid-heating conditions and those obtained from elevated-temperature stress-strain tests for 1/2-hour exposure. Master yield- and rupture-stress curves based on the use of a linear temperature-rate parameter are included which provide a convenient method for predicting yield and rupture stresses and temperatures for different temperature rates.

NACA TM 1341

APPROXIMATE HYDRODYNAMIC DESIGN OF A FINITE SPAN HYDROFOIL. (Priblizhennyi gidrodinamicheskii raschet podvodnogo kryla konechnogo razmakha). A. N. Vladimirov. June 1955. 68p. diagrs., 5 tabs. (NACA TM 1341. Trans. from Central Aero-Hydrodynamical Institute, Rept. 311, 1937).

Previous work on the motion of various bodies under the surface of a heavy fluid is discussed. The solution of the motion of a flat plate by Keldysh and Lavrentiev is applied to the motion of a hydrofoil, making possible the presentation of charts for determining the lift and resistance of an infinite span hydrofoil operating in a heavy frictionless fluid having infinite depth below the free water surface. Consideration is given to the effects of viscosity and a method is suggested to correct for the finite span. The effect of the water surface on the downwash behind the foil is also discussed. A comparison of theoretical results obtained from this work with experimental data indicates that a basis for the approximate hydrodynamic design of a finite span hydrofoil has been achieved.

NACA TN 3378

ACOUSTICAL TREATMENT FOR THE NACA 8- BY 6-FOOT SUPERSONIC PROPULSION WIND TUNNEL. Leo L. Beranek, Samuel Labate and Uno Ingard, Bolt Beranek and Newman, Inc. June 1955. 86p. diagrs., photo., 7 tabs. (NACA TN 3378)

*AVAILABLE ON LOAN ONLY.
ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

This report summarizes the results of a project at the Lewis Flight Propulsion Laboratory to silence the 8- by 6-foot supersonic wind tunnel. Sound measurements in the neighborhood surrounding the tunnel were conducted to evaluate the noise-attenuation requirements. A muffler-development program was continued until these attenuations were achieved. The final design for the acoustic treatment is described and experimental performance curves are compared with anticipated theoretical results.

NACA TN 3382

EXPERIMENTS WITH A ROTATING-CYLINDER VISCOMETER AT HIGH SHEAR RATES. J. A. Cole, R. E. Petersen and H. W. Emmons, Harvard University. June 1955. 31p. diagrs., tab. (NACA TN 3382)

Two straight mineral oils and a polymer-containing oil have been tested in a rotating-cylinder viscometer at high shear rates (maximum 0.25 million reciprocal seconds) and the accompanying heat effects have been investigated. The torque measurements are of low accuracy and fail to establish the moderately non-Newtonian behavior of the polymer-containing oil, but the temperature measurements, which are in good agreement with a thermal analysis, do indicate the presence of temporary viscosity decrease at high shear rates for this oil.

NACA TN 3411

PRESSURE WAVES GENERATED BY ADDITION OF HEAT IN A GASEOUS MEDIUM. Boa-Teh Chu, Johns Hopkins University. June 1955. 47p. diagrs. (NACA TN 3411)

The approximate formula of a linearized solution for the pressure field generated by a moderate rate of heat release is given. The analogies between the pressure waves generated by heat release and those generated by (1) mass release, (2) piston motion, or (3) a two-dimensional body in a supersonic stream are established analytically. The exact solution of an idealized problem in which heat is released uniformly at a section of tube with a given rate, large or small, is also constructed. The corresponding problems in three dimensions are also solved. Some applications of the theory are given.

NACA TN 3412

CREEP AND CREEP-RUPTURE CHARACTERISTICS OF SOME RIVETED AND SPOT-WELDED LAP JOINTS OF AIRCRAFT MATERIALS. Leonard Mordfin, National Bureau of Standards. June 1955. 53p. diagrs., photos., 6 tabs. (NACA TN 3412)

Equipment, test techniques, and results are presented for an experimental investigation of the creep of lap joints. Riveted aluminum-alloy joints fabricated from 75S-T6 and 24S-T3 sheet with 24S and 24S-T31 rivets were tested at 300°, 400°, and 500° F. Spot-welded joints of 1/4-hard, type 301 stainless steel were tested at 800° F. Each type of joint was also tested in tension at room temperature.

NACA TN 3416

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE EFFECT OF TUNNEL WALLS ON THE FORCES ON AN OSCILLATING AIRFOIL IN TWO-DIMENSIONAL SUBSONIC COMPRESSIBLE FLOW. Harry L. Runyan, Donald S. Woolston and A. Gerald Rainey. June 1955. 41p. diagrs., photo. (NACA TN 3416)

The integral equation defining the problem of an oscillating wing in a tunnel is treated and is presented in a form adapted to calculations. Application is made to a number of examples to illustrate the influence on the magnitude of wall effects of variations in frequency, Mach number, and ratio of tunnel height to wing semichord. Comparison is made with experimental measurements for several subsonic Mach numbers.

NACA TN 3448

THEORETICAL ANALYSIS OF INCOMPRESSIBLE FLOW THROUGH A RADIAL-INLET CENTRIFUGAL IMPELLER AT VARIOUS WEIGHT FLOWS. I - SOLUTION BY A MATRIX METHOD AND COMPARISON WITH AN APPROXIMATE METHOD. Vasily D. Prian, James J. Kramer and Chung-Hua Wu. June 1955. 39p. diagrs., tab. (NACA TN 3448)

A method for the solution of the incompressible, nonviscous flow through a centrifugal impeller, including the inlet region, is presented. Several numerical solutions are obtained for four weight flows through an impeller at one operating speed. The results are presented in a series of figures showing streamlines and resultant velocity contours. A comparison is made with the results obtained by use of a rapid approximate method of analysis.

NACA TN 3449

THEORETICAL ANALYSIS OF INCOMPRESSIBLE FLOW THROUGH A RADIAL-INLET CENTRIFUGAL IMPELLER AT VARIOUS WEIGHT FLOWS. II - SOLUTION IN LEADING-EDGE REGION BY RELAXATION METHODS. James J. Kramer. June 1955. 19p. diagrs. (NACA TN 3449)

The detailed solution of the flow around the blade nose of a 48-inch-diameter radial-inlet centrifugal impeller has been obtained by relaxation methods for four weight flows. The results are presented in a series of figures showing streamlines and relative velocity contours. Minimum velocity gradients around the blade nose occurred for the weight flow corresponding to a mean angle of attack of -4.6° computed from blade speed and an upstream axial-radial velocity for which blade blockage has been taken into account. A small positive local angle of attack seems desirable for blades with rounded leading edges.

NACA TN 3457

ESTIMATION OF INLET LIP FORCES AT SUBSONIC AND SUPERSONIC SPEEDS. W. E. Moeckel. June 1955. 12p. diagrs. (NACA TN 3457)

The effects of inlet lip thickness on inlet performance are estimated as functions of mass flow for subsonic and supersonic flight speeds. At subsonic speeds, pressure-recovery losses and additive drag are shown to decrease linearly with increasing lip frontal area if the maximum suction force is attained. At supersonic speeds, inlet drag increases linearly with inlet lip frontal area at full mass flow. For reduced mass flow, some reduction in additive drag is possible with lips of moderate thickness, but the magnitude of this reduction becomes negligible as flight speed increases.

NACA TN 3461

TURBULENT-HEAT-TRANSFER MEASUREMENTS AT A MACH NUMBER OF 1.62. Maurice J. Brevoort and Bernard Rashis. June 1955. 15p. diagrs., tab. (NACA TN 3461)

An axially symmetric annular nozzle was used to obtain essentially flat-plate results for turbulent-heat-transfer coefficients and temperature-recovery factors. The test results are for a Mach number of 1.62 and for a Reynolds number range of 7.22×10^5 to 1.20×10^8. The heat-transfer-coefficient results agree with theoretical results for $M = 1.60$ and $T_w/T_\infty = 1.60$. The recovery factors are on the average 1.5 percent lower than data for a Mach number of 2.4.

NACA TN 3499

CALCULATION OF THE SUPERSONIC PRESSURE DISTRIBUTION ON A SINGLE-CURVED TAPERED WING IN REGIONS NOT INFLUENCED BY THE ROOT OR TIP. Walter G. Vincenti and Newman H. Fisher, Jr. June 1955. 32p. diagrs. (NACA TN 3499)

The shock-expansion method for the calculation of the pressures on cylindrical wings in supersonic flow is extended to tapered wings made up of single-curved surfaces. The method applies in regions where (a) the component of velocity normal to the surface rulings is supersonic and (b) the flow is not influenced by tips or junctures. In these regions the flow is defined by a pair of ordinary differential equations whose solution is readily obtained by numerical means. Results are shown and discussed for a representative triangular wing.

NACA TN 3502

THE TRANSONIC CHARACTERISTICS OF 38 CAMBERED RECTANGULAR WINGS OF VARYING ASPECT RATIO AND THICKNESS AS DETERMINED BY THE TRANSONIC-BUMP TECHNIQUE. Warren H. Nelson and Walter J. Krumm. June 1955. 173p. diagrs., photos. (NACA TN 3502. Formerly RM A52D11)

An investigation was made in the Ames 16-foot high-speed wind tunnel utilizing the transonic-bump technique to determine the aerodynamic characteristics at transonic Mach numbers of 38 cambered rectangular wings. The wings had aspect ratios of 4, 3, 2, 1.5, and 1, and NACA 63A2XX and 63A4XX sections with thickness-to-chord ratios of 10, 8, 6, 4, and 2 percent. The Mach number range was 0.6 to 1.12 with corresponding Reynolds numbers of 1.7 to 2.2 million. The data are presented without analysis.

BRITISH REPORTS

N-36887*

Aeroplane and Armament Experimental Establishment (Gt. Brit.) DETERMINATION OF THE VARIATION WITH ALTITUDE OF THE RECOVERY FACTOR OF AIR THERMOMETERS. December 17, 1954. 28p. diagrs., photos., 10 tabs. (AAEE/Tech/111)

Tests were made for the standard knife edge and two other available air thermometer bulbs. The results show a significant decrement with altitude in the value of the recovery factor of the order of 0.2 between 5,000 and 40,000 feet. That means a change from 0.69 to 0.51 in the values for the standard knife edge bulb. In view of these findings, it appears imperative in performance tests which are sensitive to ambient air temperature, to determine the recovery factor of the outside air thermometer over the altitude range of the aircraft. Alternatively, there is a need for an air thermometer whose recovery factor remains constant with change of altitude.

Royal Aircraft Establishment (Gt. Brit.) THE TORSIONAL VIBRATIONS OF A CLASS OF THIN, TAPERED, SOLID WINGS. Elizabeth A. Frost. January 1955. 22p. diagrs., tab. (RAE Tech. Note Structures 152)

This report considers the torsional vibrations of thin solid wings of doubly symmetrical chordwise section, with linear variation of chord and parabolic variation of thickness. Frequencies of symmetrical and antisymmetrical vibrations are presented graphically for a range of values of the aspect ratio and the taper ratio.

N-36902*

Royal Aircraft Establishment (Gt. Brit.) TESTS ON THE PROTECTION GIVEN TO METALS BY ETCH PRIMERS. H. G. Cole. January 1955. 13p. 6 tabs. (RAE Tech. Note Met. 209)

Long term seawater spray corrosion tests have shown that the relative performance of painting schemes based on six commercial etch primers varied markedly from metal to metal. On zinc and cadmium-plated steel, the etch primer schemes gave better performance than conventional paints applied over classical methods of surface treatment. On steel and aluminum alloys, the use of etch primers is an acceptable substitute for conventional methods of protection, provided that the etch primer is followed by a full protective scheme. Their use on magnesium alloys is risky because of the danger of attack on the metal.

Royal Aircraft Establishment (Gt. Brit.) A JUNCTION TRANSISTOR DECADE COUNTER. H. W. P. Knapp. January 1955. 11p. diagrs., photo. (RAE Tech. Note GW 354)

A junction transistor decade counter is described which is tolerant of supply voltage, input amplitude, and ambient temperature variations.

DECLASSIFIED NACA REPORTS

NACA RM A52G17

THE USE OF LEADING-EDGE AREA SUCTION TO INCREASE THE MAXIMUM LIFT COEFFICIENT OF A 35° SWEPT-BACK WING. Curt A. Holzhauser and Robert K. Martin. September 1952. 37p. diagrs., photo., 3 tabs. (NACA RM A52G17) (Declassified from Confidential, 6/10/55)

Measurements were made of the increase in lift coefficient obtained with various amounts of area suction. Flow coefficients and power inputs required to obtain these lift coefficients were measured at free-stream velocities from 112 to 180 feet per second. With full-span area suction and a maximum chordwise opening of 2.2 percent, the $C_{L_{max}}$ of the model with flaps deflected was increased from 1.33 to 2.00 with a flow coefficient of 0.00108 and a suction horsepower of 47 at a free-stream velocity of 129 feet per second. There appeared to be no unacceptable characteristics that a 35° swept-wing airplane would exhibit in low-speed flight as a result of employing area suction.

NACA RM L7F30

FREE-FLIGHT INVESTIGATION OF CONTROL EFFECTIVENESS OF FULL-SPAN, 0.2-CHORD PLAIN AILERONS AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS TO DETERMINE SOME EFFECTS OF WING SWEEPBACK, TAPER, ASPECT RATIO, AND SECTION-THICKNESS RATIO. Carl A. Sandahl. August 13, 1947. 16p. diagrs., photos., tab. (NACA RM L7F30) (Declassified from Confidential, 6/10/55)

The aileron control characteristics of untapered, 45° sweptback wings of aspect ratio 3 were found to be generally the same for the 65-006 and 65-009 sections. The tapered 45° sweptback wings of aspect ratio 3 and 65-009 section exhibited a small abrupt change in rolling effectiveness from M = 0.92 to 1.00 which was not characteristic of untapered wings tested having the same sweep, aspect ratio, and section. A reduction in aspect ratio from 3 to 1.75 for unswept, untapered wings gave an increase in rolling effectiveness. Both aspect-ratio configurations showed undesirable control characteristics at transonic speeds.

NACA RM L51F11

RECENT EXPERIMENTAL FLUTTER STUDIES. Arthur A. Regier and Dennis J. Martin. June 12, 1951. 18p. diagrs. (NACA RM L51F11) (Declassified from Confidential, 6/10/55)

This paper presents in a rather brief fashion some of the highlights of recent experimental flutter studies. Material from several papers is brought together and compared. The material includes trend studies of flutter of swept and unswept wings at transonic speeds; studies of a bending-type flutter of swept wings; flutter involving body modes; and preliminary studies of M and W and delta wing configurations.

NACA RM L51L03

PRESSURE DISTRIBUTIONS AT MACH NUMBERS FROM 0.6 TO 1.9 MEASURED IN FREE FLIGHT ON A PARABOLIC BODY OF REVOLUTION WITH SHARPLY CONVERGENT AFTERBODY. William E. Stoney, Jr. April 1952. 34p. diagrs., photos. (NACA RM L51L03) (Declassified from Confidential, 6/10/55)

A flight test was made, at Mach numbers from 0.6 to 1.9, of a fin-stabilized parabolic body of revolution having a sharply convergent afterbody. Pressures were measured at eight longitudinal stations on the body and on the base with and without a simulated wind-tunnel sting extending from the base of the model. The results were compared with theoretical determinations of the pressures by linear and exact methods.

NACA RM L52L05

WIND-TUNNEL INVESTIGATION OF STALL CONTROL BY SUCTION THROUGH A POROUS LEADING EDGE ON A 37° SWEPTBACK WING OF ASPECT RATIO 6 AT REYNOLDS NUMBERS FROM 2.50×10^6 to 8.10×10^6. Robert R. Graham and William A. Jacques. March 1953. 67p. diagrs., photo., 2 tabs. (NACA RM L52L05) (Declassified from Confidential, 6/10/55)

Stall control by suction through a porous leading-edge upper surface was investigated on a plain wing and on the same wing with half-span split or double slotted flaps. Some effects of varying the chordwise and spanwise extent of porosity and varying the flow coefficient were investigated on the plain wing. Force and moment data are presented along with minimum measured leading-edge pressure coefficients across the span of the wing.

NACA RM L53C02

THE BASE PRESSURE AT SUPERSONIC SPEEDS ON TWO-DIMENSIONAL AIRFOILS AND BODIES OF REVOLUTION (WITH AND WITHOUT FINS) HAVING TURBULENT BOUNDARY LAYERS. Eugene S. Love. April 1953. 65p. diagrs., photos. (NACA RM L53C02) (Declassified from Confidential, 6/10/55)

An analysis is made of available experimental data to show the effect of most of the variables that are more predominant in determining base pressure at supersonic speeds. The analysis is restricted to turbulent boundary layers and covers two-dimensional bases and the bases of bodies of revolution, with and without stabilizing fins. An analogy to the pressure rise required to separate the boundary layer is presented as are simple semiempirical methods for the estimation of base pressure.

NACA RM L53F15a

STUDIES OF THE SPEED STABILITY OF A TANDEM HELICOPTER IN FORWARD FLIGHT. Robert J. Tapscott and Kenneth B. Amer. August 1953. 35p. diagrs., photos., tab. (NACA RM L53F15a) (Declassified from Confidential, 6/10/55)

Analytical and experimental studies and corresponding pilots' opinions of the speed stability of a tandem helicopter are presented and means for improving the speed stability are discussed. An analytical expression is derived for use in predicting changes in speed stability of a tandem helicopter brought about by changes in the rotor geometry. Constants for use with the analytical expression are presented in chart form.

NACA RM L53G15a

THE VARIATION OF ATMOSPHERIC TURBULENCE WITH ALTITUDE AND ITS EFFECT ON AIRPLANE GUST LOADS. Robert L. McDougal, Thomas L. Coleman and Philip L. Smith. November 1953. 16p. diagrs., 2 tabs. (NACA RM L53G15a) (Declassified from Confidential, 6/10/55)

Analysis of turbulence data for altitudes up to 60,000 feet indicates substantial reductions in the amount and relative intensity of the turbulence at the higher altitudes. The implications of these reductions in the turbulence are discussed in regard to the gust loads for assumed airplane operations.

NACA RM L54B16b

FLIGHT TESTS OF A 0.4-SCALE MODEL OF A STAND-ON TYPE OF VERTICALLY RISING AIRCRAFT. Marion O. McKinney and Lysle P. Parlett. March 1954. 23p. diagrs., photos. (NACA RM L54B16b) (Declassified from Confidential, 6/10/55)

The results of a free-flight investigation of the stability and control of a 0.4-scale model of a stand-on type of vertically rising aircraft in take-offs and landings and in hovering and forward flight are presented. The aircraft component of the model consisted of a motor-driven, single-rotation propeller in a short shroud with antitorque vanes and control surfaces at the rear of the shroud.

CURRENT NACA REPORTS

NACA Rept. 1174

THE STRUCTURE OF TURBULENCE IN FULLY DEVELOPED PIPE FLOW. John Laufer, National Bureau of Standards. 1954. ii, 18p. diagrs. (NACA Rept. 1174. Formerly TN 2954)

Measurements, principally with a hot-wire anemometer, were made in fully developed turbulent flow in a 10-inch pipe at speeds of 10 and 100 feet per second. It is shown that rates of turbulent-energy production, dissipation, and diffusion have sharp maximums near the edge of the laminar sublayer and that there exist a strong movement of kinetic energy away from this point and an equally strong movement of pressure energy toward it. It is suggested that the flow field may be divided into three regions: Wall proximity where turbulence production, transfer, and viscous action are of about equal importance; the central region of the pipe where energy diffusion predominates; and the intermediate region where the local rate of change of turbulent-energy production dominates the energy received by diffusive action.

NACA Rept. 1181

STRUCTURAL RESPONSE TO DISCRETE AND CONTINUOUS GUSTS OF AN AIRPLANE HAVING WING-BENDING FLEXIBILITY AND A CORRELATION OF CALCULATED AND FLIGHT RESULTS. John C. Houbolt and Eldon E. Kordes. 1954. ii, 22p. diagrs., 4 tabs. (NACA Rept. 1181. Formerly TN 3006)

An analysis is made of the structural response to gusts of an airplane having the degrees of freedom of vertical motion and wing bending flexibility. Convenient solutions of the response equations are developed for discrete and sinusoidal-gust encounter, and the procedure is given for treating the realistic condition of continuous random atmospheric turbulence. Flight and calculated results are then given for several airplanes to evaluate the influence of wing bending flexibility on the structural response to gusts. The discrete-gust approach is shown to reveal the general nature of the flexibility effects and leads to qualitative correlation with flight results. The continuous-turbulence approach shows good quantitative correlation and indicates a much greater degree of resolution of flexibility effects.

NACA Rept. 1193

THEORETICAL PERFORMANCE CHARACTERISTICS OF SHARP-LIP INLETS AT SUBSONIC SPEEDS. Evan A. Fradenburgh and DeMarquis D. Wyatt. 1954. ii, 8p. diagrs. (NACA Rept. 1193. Formerly TN 3004)

A method is presented for the estimation of the subsonic-flight-speed characteristics of sharp-lip inlets applicable to supersonic aircraft. The analysis, based on a simple momentum balance consideration, permits the computation of inlet pressure recovery - mass-flow relations and additive-drag coefficients for forward velocities from zero to the speed of sound. Operation of a sharp-lip inlet at velocity ratios less than 1.0 results in an additive drag that is not cancelled by lip suction, while at velocity ratios greater than 1.0, losses in inlet total pressures result. In particular, at the take-off condition, the total pressure and the mass flow for a choked inlet are only 79 percent of the values ideally attainable with a rounded lip.

NACA RM 54L29

METEOROLOGICAL PROBLEMS ASSOCIATED WITH COMMERCIAL TUBOJET-AIRCRAFT OPERATION. A working group of the NACA Subcommittee on Meteorological Problems. June 1955. 46p. (NACA RM 54L29)

Meteorological requirements and problems anticipated with the safe, efficient, and economical operation of commercial turbojet aircraft have been analyzed and evaluated. Problems of temperature, wind, pressure, ceiling, visibility, cloud and clear-air turbulence, icing, and communication are discussed. Characteristics such as high cruising speed, high cruise level, relatively high fuel consumption, and engine performance sensitive to temperature and air density are considered.

NACA RM E55D07b

EXPLORATORY INVESTIGATION OF FLOW IN THE SEPARATED REGION AHEAD OF TWO BLUNT BODIES AT MACH NUMBER 2. Harry Bernstein and William E. Brunk. June 1955. 27p. diagrs., photos. (NACA RM E55D07b)

Flow separation from a flat plate ahead of two blunt two-dimensional bodies was investigated at Mach number 2.0. Interferograms were obtained for the regions, and the pitot-pressure distribution and flow directions were surveyed in one of the regions. Mach numbers were generally less than 0.5 in the reverse-flow regions near the plate surface. A flow-direction survey for a model with separation at the leading edge of the flat plate showed a reverse-flow component in about half of the separated region.

NACA RM L55D21

VELOCITY DISTRIBUTIONS MEASURED IN THE SLIPSTREAM OF EIGHT-BLADE AND SIX-BLADE DUAL-ROTATING PROPELLERS AT ZERO ADVANCE. Leland B. Salters, Jr. June 1955. 27p. diagrs., photo. (NACA RM L55D21)

* AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

This report contains the results of a slipstream survey behind NACA 8.75-(5)(05)-037 eight- and six-blade dual-rotating propellers at zero advance. The slipstream-boundary cone angle was found to agree qualitatively with the theoretical angle of spread for an unheated jet.

NACA RM L55E10b

EXPERIMENTAL ANALYSIS OF MULTICELL WINGS BY MEANS OF PLASTIC MODELS. George W. Zender. June 1955. 6p. diagrs. (NACA RM L55E10b)

The stresses and deflections of a plastic model of a delta multicell wing are compared with results obtained by the use of the Cal-Tech analog computer. The comparison indicates that valuable information may be obtained for experimental structural analyses from tests of plastic models.

NACA RM L55E12c

VERTICAL AND DRAG GROUND-REACTION FORCES DEVELOPED IN LANDING IMPACTS OF A LARGE AIRPLANE. Richard H. Sawyer, Albert W. Hall and James M. McKay. June 1955. 12p. diagrs. (NACA RM L55E12c)

Tests were conducted on a large-bomber-type airplane to determine the ground reactions imposed on the landing gear under actual landing conditions. The program covered landings made at vertical velocities up to 8.5 feet per second and forward speeds at contact from 95 to 120 miles per hour. Landings were made on both wet and dry concrete runways. Results are presented of the effects of vertical velocity at contact and the effects of runway surface condition (wet and dry) on the vertical and drag ground reactions obtained during the landing impact.

NACA TM 1391

REDUCTION OF THE SHIMMY TENDENCY OF TAIL AND NOSE-WHEEL LANDING GEARS BY INSTALLATION OF SPECIALLY DESIGNED TIRES. (Verminderung der Flatterneigung von Sporn- und Bugwerken durch Einbau besonders geformter Reifen). H. Schrode. July 1955. 13p. diagrs. (NACA TM 1391. Trans. from Deutschen Versuchsanstalt für Luftfahrt E. V., Berlin-Adlershof. Technische Berichte, v. 10, 1943, p. 113-116)

An experimental study is made of the shimmy tendency of several conventional and modified German aircraft tires ranging in size from about 11 to 15 inches in diameter. The effects of tire size, shape, loading and wear, type of rolling motion (acceleration or deceleration), trail and rolling velocity on the shimmy tendency are investigated. It is found that tires of small main dimensions with stiff flattened running surfaces, high lateral and torsional stiffnesses and small ground contact areas are favorable for reduction of the shimmy tendency.

NACA TN 3299

MAXIMUM THEOREMS AND REFLECTIONS OF SIMPLE WAVES. P. Germain, Brown University. June 1955. 22p. (NACA TN 3299)

The properties of the solutions corresponding to the reflection of a centered simple wave along a straight line or along a free streamline are shown to be closely related to some important theorems predicting "a priori bounds" for special mathematical problems. These properties thus appear to be a physical interpretation of those theorems.

NACA TN 3421

AERODYNAMICS OF A RECTANGULAR WING OF INFINITE ASPECT RATIO AT HIGH ANGLES OF ATTACK AND SUPERSONIC SPEEDS. John C. Martin and Frank S. Malvestuto, Jr. July 1955. 114p. diagrs., tab. (NACA TN 3421)

Perturbation of the flow over a two-dimensional flat plate at finite angles of attack is used to obtain a first-order evaluation of damping in roll, lift and moment due to an increment in angle of attack, and lift and moment due to steady pitching velocity for a rectangular wing of infinite aspect ratio at supersonic speeds. Results are valid for the range of Mach number and angle of attack for which the flow behind the shock is supersonic. The analysis is based on the equations for rotational flow so that the change in entropy is taken into account. Approximate estimates of a number of aerodynamic derivatives of rectangular wings at finite angles of attack are also presented.

NACA TN 3443

SHEARING EFFECTIVENESS OF INTEGRAL STIFFENING. Robert F. Crawford and Charles Libove. June 1955. 37p. diagrs., photo., tab. (NACA TN 3443)

Values of coefficients for defining the effectiveness of integral stiffeners in resisting shear deformations of the plate of which they are an integral part are presented for a variety of proportions of rectangular stiffeners with circular fillets. Formulas are given in which these coefficients may be employed to calculate the elastic constants associated with the twisting and shearing of integrally stiffened plates. The size of fillet radius is shown to contribute appreciably to the degree of penetration of the stresses from the skin into the stiffener.

NACA TN 3455

RECOVERY AND TIME-RESPONSE CHARACTERISTICS OF SIX THERMOCOUPLE PROBES IN SUBSONIC AND SUPERSONIC FLOW. Truman M. Stickney. July 1955. 25p. diagrs., photos., 2 tabs. (NACA TN 3455)

Experimental data obtained from three shielded and three unshielded thermocouple probes are presented. Data taken in air at room temperature over the ranges 0.2 to 2.2 Mach number and 0.2 to 2.2 atmospheres total pressure show reproducible systematic variations of recovery with Mach number, ambient pressure, flow angle, and probe design. Time-constant data determined at Mach 0.2 and room temperature and pressure indicate that unshielded probes are several times faster in response to temperature changes than shielded probes.

NACA TN 3456

PROPAGATION OF A FREE FLAME IN A TURBULENT GAS STREAM. William R. Mickelsen and Norman E. Ernstein. July 1955. 89p. diagrs., photos., 2 tabs. (NACA TN 3456)

Effective turbulent free-flame speeds measured in turbulent, flowing propane-air mixtures were found to have statistical distributions about mean values. The statistical spread was greater for rich and lean fuel-air ratios and at high turbulence intensities. The measured flame speeds, together with hot-wire-anemometer measurements, formed a basis for comparison with three theories and other types of flames. Although the free-flame speeds are lower than those for turbulent Bunsen and stabilized flames, values calculated from the Tucker analysis and a modified Scurlock-Grover analysis seem to form an upper limit to the turbulent free-flame-speed data.

NACA TN 3458

UNSTABLE CONVECTION IN VERTICAL CHANNELS WITH HEATING FROM BELOW, INCLUDING EFFECTS OF HEAT SOURCES AND FRICTIONAL HEATING. Simon Ostrach. July 1955. 38p. diagrs., 3 tabs. (NACA TN 3458)

Solutions are found for the cases in which the wall temperature variations are linear and (1) the wall temperatures are specified, (2) the walls are both insulated, and (3) the net mass flow in the channel is zero. The heat sources affect the flows in essentially a quantitative manner, changing the stability characteristics of the flows only when both walls are insulated. The effects of frictional heating are important in certain ranges of the parametric values, especially near critical Rayleigh numbers.

NACA TN 3459

SIMPLIFIED PROCEDURES AND CHARTS FOR THE RAPID ESTIMATION OF BENDING FREQUENCIES OF ROTATING BEAMS. Robert T. Yntema. June 1955. ii, 90p. diagrs., 6 tabs. (NACA TN 3459. Supersedes and extends RM L54G02)

A Rayleigh energy approach utilizing the nonrotating-beam bending modes in the determination of the bending frequencies of the rotating beam is evaluated and is found to give good practical results for helicopter blades. Charts are presented for the rapid estimation of the first three bending frequencies for rotating and nonrotating cantilever and hinged beams. A more exact mode-expansion method used in evaluating the Rayleigh approach is also described. Numerous mode shapes and derivatives are presented in tabular form and discussed.

NACA TN 3500

CORRECTION OF ADDITIONAL SPAN LOADINGS COMPUTED BY THE WEISSINGER SEVEN-POINT METHOD FOR MODERATELY TAPERED WINGS OF HIGH ASPECT RATIO. John DeYoung and Walter H. Barling, Jr. July 1955. 31p. diagrs. (NACA TN 3500)

A simple procedure is found which results in more accurate span loadings, lift-curve slopes, and spanwise centers of pressure being read directly from the charts of NACA Report 921. The new results compare very well with experiment and with theoretical results believed to be accurate.

NACA TN 3501

THE TRANSONIC CHARACTERISTICS OF 22 RECTANGULAR, SYMMETRICAL WING MODELS OF VARYING ASPECT RATIO AND THICKNESS. Warren H. Nelson and John B. McDevitt. June 1955. 109p. diagrs., photos. (NACA TN 3501. Formerly RM A51A12)

An investigation utilizing the transonic-bump technique was made to determine the aerodynamic characteristics at transonic Mach numbers of 22 rectangular wings having aspect ratios of 6, 4, 3, 2, 1.5, 1, and 0.5, and NACA 63A0XX sections with thickness-to-chord ratios of 10, 8, 6, 4, and 2 percent. The Mach number range was 0.4 to 1.1, corresponding under the test conditions to a Reynolds number range from 1.25 to 2.05 million. These data are presented without analysis.

NACA TN 3504

EFFECT OF TRAILING-EDGE THICKNESS ON LIFT AT SUPERSONIC VELOCITIES. Dean R. Chapman and Robert H. Kester. June 1955. 19p. diagrs. (NACA TN 3504. Formerly RM A52D17)

Lift forces on various rectangular-plan-form wings were measured in the Mach number range between 1.5 and 3.1 at Reynolds numbers between 0.55 and 2.2 million. The wings differed in trailing-edge thickness, profile shape, maximum thickness ratio, and aspect ratio. Measurements were made on wings with and without a boundary-layer trip and are compared to theoretical calculations. Calculated results using shock-expansion theory are presented for Mach numbers up to 10. In general, thickening the trailing edge resulted in an increase in lift-curve slope. This increase varied between a few percent and about 15 percent, depending primarily on the trailing-edge thickness. Calculations indicate that somewhat greater increases are possible at high supersonic Mach numbers.

NACA TN 3508

LAMINAR FREE CONVECTION ON A VERTICAL PLATE WITH PRESCRIBED NONUNIFORM WALL HEAT FLUX OR PRESCRIBED NONUNIFORM WALL TEMPERATURE. E. M. Sparrow. July 1955. 34p. diagrs. (NACA TN 3508)

An analysis is made for laminar free convection on a vertical plate with prescribed nonuniform thermal conditions at the surface. For the situation where the wall-heat-flux variation is prescribed, graphs are presented from which the resulting variation of the wall temperature and local heat-transfer coefficient can be found. Results for the important special case of uniform wall heat flux are given. For the situation where the wall-temperature variation is prescribed, graphs are given for the over-all heat-transfer rate and local heat-transfer coefficient. All results are given for Prandtl numbers from 0.01 to 1000. Boundary-layer theory is used in conjunction with the Kármán-Pohlhausen method.

NACA TN 3513

HEAT TRANSFER AT THE FORWARD STAGNATION POINT OF BLUNT BODIES. Eli Reshotko and Clarence B. Cohen. July 1955. 17p. diagrs. (NACA TN 3513)

Relations are presented for the calculation of heat transfer at the forward stagnation point of both two-dimensional and axially symmetric blunt bodies. The relations for the heat transfer, which were obtained from exact solutions to the equations of the laminar boundary layer, are presented in terms of the local velocity gradient at the stagnation point. These exact solutions include effects of variation of fluid properties, Prandtl number, and transpiration cooling. Examples illustrating the calculation procedure are presented.

NACA TN 3517

APPROXIMATE METHOD FOR DETERMINING EQUILIBRIUM OPERATION OF COMPRESSOR COMPONENT OF TURBOJET ENGINE. Merle C. Huppert. July 1955. 25p. diagrs. (NACA TN 3517)

A method is presented for estimating the equilibrium operating line for a compressor as a component part of a turbojet engine. The results of this analysis are presented in chart form to facilitate rapid determination of the equilibrium operating line. Predicted and measured equilibrium operating conditions are compared in terms of compressor pressure ratio and equivalent weight flow; satisfactory agreement is indicated.

THE EFFECT OF NUMBER OF RIGGING LINES ON THE STRENGTH OF AN EXETER TYPE 12 PARACHUTE CANOPY. J. Picken. January 1955. 11p. diagrs., photos., 2 tabs. (RAE Tech. Note Mech. Eng. 197)

The number of rigging lines has been shown to have an effect on the strength of an Exeter-type 12 parachute canopy. In a series of flight tests it was demonstrated that a canopy rigged with eight lines is not so strong as one rigged with 16 lines. Amendments to the appropriate design formula are suggested.

THE ELECTRICAL RESISTIVITY OF SODIUM BETWEEN 78° K AND 372° K. F. J. Bradshaw and S. Pearson. February 1955. 14p. diagrs. (RAE Met. 84)

The electrical resistivity of sodium has been measured from 78° K to slightly beyond the melting point. The specimens used consisted of distilled sodium in fine thin-walled nickel tubes. The results are compared with previously published figures. There is a small rise in the R/T v. T curve in the region 300° K to the melting point, which is not simply accountable for by present conductivity theories, and the hypothesis that part of the high temperature resistance is due to the presence of lattice defects is considered. Measurements on solid sodium were made to within 0.04° of the melting point and the resistance increased uniformly to this temperature. Some attempts were made to measure excess resistivity due to defects retained after quenching the solid from temperatures near the melting point, or after mechanical deformation at 63° K, but these were unsuccessful.

TITANIUM-VANADIUM ALLOYS. G. I. Lewis, K. S. Jepson and H. Brooks. February 1955. 40p. diagrs., photos., 12 tabs. (RAE Tech. Note Met. 208)

Titanium-base alloys containing 5- to 30-percent vanadium were prepared as 0.07-in. thick rolled strip and tested in various conditions to determine the best tensile properties obtainable from them by heat treatment. An alloy with 16-percent vanadium showed most promise as a structural sheet material. After quenching from 800° C it had a tensile strength of 51 tons/sq in. with 29-percent total and 26-percent uniform elongation, and a minimum bend radius of IT. By overaging at 400 to 475° C, this soft condition could be converted to various hard conditions with strengths ranging from 71 tons/sq in. with 12-1/2 percent elongation to 88 tons/sq in. with 5-percent elongation. When aged to a 20° C strength of 81 tons/sq in., the tensile and shear moduli were 14.3 and 5.4 x 10^6 lb/sq in., respectively; the strength at 350° C was 65 tons/sq in. and after 1000 hours exposure at this temperature, the 20° C properties were substantially unchanged. The density of the alloy was 4.74 gm/cc or 0.17 lb/cu in. A number of ternary alloys based on the Ti-16-percent V composition were also examined.

A CONSTRUCTIONAL METHOD FOR MINIMISING THE HAZARD OF CATASTROPHIC FAILURE IN A PRESSURE-CABIN. D. Williams. March 1955. 7p. (RAE Tech. Note Structures 156)

A method is put forward for substantially reducing the chances of a local failure in the shell of a pressure cabin from developing into catastropic failure of the cabin. The increased safety is achieved without weight penalty, and consists essentially in using closely spaced (10 inches or thereabouts) transverse flat bands, the material for which is obtained by reducing the sheet thickness normally available for the shell walls.

Nat. Gas Turbine Establishment (Gt. Brit.)
SOME EFFECTS OF SCALE AND MATERIAL ON THE BURSTING SPEEDS OF TURBINE DISCS. A. Graham, T. M. Jones and V. C. H. Bailey. January 1955. 12p. diagrs., 5 tabs. (NGTE R.166)

The measured bursting speeds of turbine disks of related profiles and several diameters in several materials are compared. Within the experimental range, the desirable amount of reinforcement about a central bore is found to vary with material and scale, but a moderate amount of reinforcement will offset the weakness due to a bore. Larger disks in various materials appear to behave like smaller disks in a brittle material. It is concluded that model experiments offer a better basis for comparison of disk profiles than elastic calculations.

Royal Aircraft Establishment (Gt. Brit.)
LUBRICATION: THE RATE OF SPREADING AND CREEP OF OILS AND OTHER LIQUIDS OVER SOLID SURFACES. E. B. Bielak, G. F. N. Calderwood and E. J. W. Mardles. March 1955. 21p. diagrs., 3 tabs. (RAE Tech. Note Chem. 1245)

The rate of radial spreading of liquid pools over and between horizontal surfaces and of the spontaneous movement of liquid columns into horizontal capillaries has been measured for a variety of liquids under different conditions of test. A resistance to flow, due to thin films extending from the liquid periphery, and which is variable with time of resting, rate of movement, etc., has been recorded. The slow movement which is non-Newtonian and affected by a number of specific factors other than the physical ones of viscosity, density, etc. can be correlated with results for several liquid properties, that is, friction, adhesion, and the dispersive power of the liquids for finely divided solids. The contact angle and hysteresis of contact angles hypotheses are inadequate for explaining the results obtained. The significance of the results in relation to lubrication theory is discussed briefly.

Royal Aircraft Establishment (Gt. Brit.)
LOADING CONDITIONS FOLLOWING AN AUTOMATIC PILOT FAILURE (RUDDER CHANNEL). D. R. Puttock. February 1955. 35p. diagrs., tab. (RAE Tech. Note Structures 154)

A method is presented for the determination of the critical loading conditions of aircraft that ensue from an automatic pilot failure in the rudder channel. General expressions have been derived through response theory for the angle of sideslip, fin-and-rudder load, and lateral acceleration both at the c. g. of the aircraft and at the tail, that result from the sequence of rudder movements assumed to follow an automatic pilot failure. Analysis of these general expressions leads to formulas suitable for assessing the numercial values of the critical loading conditions and it is suggested that these formulas might form a basis for the interpretation of the appropriate design requirement. An example is given to illustrate the type of response produced by a rudder channel failure and the calculation procedure.

N-38045*

Royal Aircraft Establishment (Gt. Brit.)
LOADING CONDITIONS FOLLOWING AN AUTOMATIC PILOT FAILURE (ELEVATOR CHANNEL). D. R. Puttock. February 1955. 50p. diagrs., tab. (RAE Tech. Note Structures 153)

A proposal is made for a standard procedure for calculating the critical loading conditions ensuing from an automatic pilot failure in the elevator channel. General expressions are derived through response theory for the increments in normal acceleration at the c. g. of the aircraft, normal acceleration at the tail, and aerodynamic load on the tailplane which result from the sequence of elevator movements assumed to follow a failure. Analysis of these general expressions leads to formulas suitable for assessing the numerical values of the critical loads on the wing and tailplane. The influence of the sequence of elevator movements on the loading conditions is discussed with reference to an example.

INTERPRETATION OF WIND-TUNNEL DATA IN TERMS OF DYNAMIC BEHAVIOR OF AIRCRAFT AT HIGH ANGLES OF ATTACK. Ralph W. Stone, Jr. (Presented to Wind Tunnel and Model Testing Panel of Advisory Group for Aeronautical Research and Development, Ottawa, Canada, June 10-14, 1955) 32p. diagrs.

With the advent of jet-propelled aircraft and flight near and beyond the speed of sound, the basic airplane configuration has changed markedly. Most noticeable and important in this change has been the trend to low-aspect-ratio wings, swept-wing plan forms, and the general concentration of weight along the fuselage. The aerodynamic characteristics which basically result from the major changes in airplane configurations and which tend to cause inadvertent excursions of airplanes to large angles of attack and sideslip are nonlinear static pitching-moment characteristics at moderately low-lift coefficients, losses in directional stability, dihedral effectiveness, and roll damping at angles below the stall; and loss of directional stability with increasing Mach number in the supersonic range. The effect of inertia coupling is also of major influence. These characteristics which can cause inadvertent and uncontrolled motions and their recognition from wind-tunnel measure-moments are discussed.

AEROELASTIC EFFECTS OF AERODYNAMIC HEATING. Hugh L. Dryden and John E. Duberg. (Presented to Fifth General Assembly of Advisory Group for Aeronautical Research and Development, Ottawa, Canada, June 10-17, 1955) 18p. diagrs.

The design of aircraft to withstand aeroelastic difficulties at high supersonic speeds will of necessity require the consideration of the effects of aerodynamic heating. Among the various aeroelastic consequences of aerodynamic heating, the reduction of over-all stiffness through the action of thermal

stress is the most novel and may well turn out to be the most serious. An appreciation of this phenomenon must become part of the working equipment of the modern aeroelastician.

GYROPLANES (HELICOPTERS) WITH ROTORS THERMOPROPELLED BY LOW-PRESSURE FLUID. (Giravions à rotors thermopropulsés par fluide moteur à basse pression). M. René Dorand. June 1955. 52p. diagrs., photo., tabs. (Trans. from Technique et Science Aéronautiques, no. 3, 1951, p. 158-189)

The propelling fluid has a compression ratio of from 1.15 to 1.4; temperature of the order of 130° C; and velocity of from 200 m/sec to 300 m/sec. It is produced by a generator placed in the fuselage and distributed by means of a rotating joint in the longerons of the rotor and escapes by means of streamline propulsion nozzles in the blade profile whose orifices are distributed over span and depth of the blade. Part of the propelling fluid is used for directional maneuvering, and in certain cases, for direct propulsion of the machine. Expensive power transmission machinery is eliminated and fuel economy results.

CURRENT NACA REPORTS

NACA RM E55E17a

PRELIMINARY DATA ON RAIN DEFLECTION FROM AIRCRAFT WINDSHIELDS BY MEANS OF HIGH-VELOCITY JET-AIR BLAST. Robert S. Ruggeri. July 1955. 17p. diagrs., photos. (NACA RM E55E17a)

Results indicate that rain deflection by jet-air blast appears feasible for flight speeds comparable with landing and take-off; however, visibility through the mist generated by raindrop breakup presents a problem. For the simulated windshield used, air-flow rates of about 3.3 lb/min-in. of span were required for adequate rain deflection at an airspeed of 135 mph. A method was devised whereby large-diameter water drops (1000 to 1500 μ) can be produced in a moving air stream, without breakup, at speeds in excess of 175 mph.

NACA RM L55E13c

A STUDY OF THE RESPONSE OF PANELS TO RANDOM ACOUSTIC EXCITATION. Robert W. Hess, Leslie W. Lassiter and Harvey H. Hubbard. July 1955. 9p. diagrs. (NACA RM L55E13c)

An application is made of the method of generalized harmonic analysis to the problem of prediction of stresses in airplane-skin panels due to excitation by jet noise. The concepts of the theory are reviewed briefly and some of the significant parameters are evaluated in the tests. Measurements of stresses in some panels due to random acoustic excitation are presented and are found to be in general agreement with calculated results.

NACA RM L55E20c

BEHAVIOR OF A CANTILEVER PLATE UNDER RAPID-HEATING CONDITIONS. Louis F. Vosteen and Kenneth E. Fuller. July 1955. 17p. diagrs. (NACA RM L55E20c)

The temperature distributions encountered in thin solid wings subjected to aerodynamic heating induce thermal stresses that may effectively reduce the stiffness of the wing. The effects of this reduction in stiffness were investigated experimentally by rapidly heating the edges of a cantilever plate. The midplane thermal stresses imposed by the nonuniform temperature distribution caused the plate to buckle torsionally, increased the deformations of the plate under a constant applied torque, and reduced the frequency of the first two natural modes of vibration. By using small-deflection theory and employing energy methods, the effect of nonuniform heating on the plate stiffness was calculated. The theory predicts the general effects of the thermal stresses, but becomes inadequate as the temperature difference increases and plate deflections become large.

NACA RM L55F10

SOME EFFECTS OF FLUID IN PYLON-MOUNTED TANKS ON FLUTTER. James R. Reese. July 1955. 7p. diagrs., tab. (NACA RM L55F10)

Fluid-dynamics studies were made of a tank of fineness ratio 7.0 which was pylon mounted on a simplified two-dimensional flutter model in order to determine the effects of the fluid on flutter. The flutter speed was found experimentally for three cases as follows: with various amounts of water in the tank, with weights having the same mass and moment of inertia as the fluid considered to be a frozen solid, and with weights having the same mass and moment of inertia as the actual fluid. The results of the two methods of fuel representation were compared with the actual-fluid case, and it was concluded that, in flutter analyses and tests, the fuel in wing tanks must be represented by the effective-moment-of-inertia values. The damping action of the fluid was also studied, and it was found that sufficient damping was present to limit the amplitude of the flutter and that, at a frequency ratio near 1.0, the fluid damping may produce an increase in the flutter speed.

NACA TM 1390

ON THE MECHANISM OF BUCKLING OF A CIRCULAR CYLINDRICAL SHELL UNDER AXIAL COMPRESSION. Y. Yoshimura. July 1955. 46p. diagrs., tab. (NACA TM 1390)

The present paper deals with the buckling of a circular cylindrical shell under axial compression from the viewpoint of energy and the characteristics of deformation. It is shown first, both theoretically and experimentally, that the reason why the buckling of a cylindrical shell is quite different from that of a flat plate is attributable to the existence of a nearly developable surface far apart from the original cylindrical surface, which is equivalent to the existence of an approximately inextensional finite deformation. Based upon this result, the experimental fact that the buckling is really not general but local, that is, that the buckled region is limited axially to a range of 1.5 times the wave length of the lobe, is explained by the theoretical result that the minimum buckling load is smaller in the local buckling than in the general buckling case. The occurrence of local

buckling is affirmed also from the viewpoint of the energy barrier to be jumped over during buckling, and from a comparison of the theoretical post-buckling state with the experimental results. Finally, the local buckling with the load applied by a spring is analyzed, and it is proved that the minimum buckling load increases with an increase of rigidity of the spring.

NACA TN 3218

FLIGHT DETERMINATION OF THE DRAG AND PRESSURE RECOVERY OF AN NACA 1-40-250 NOSE INLET AT MACH NUMBERS FROM 0.9 TO 1.8. R. I. Sears and C. F. Merlet. July 1955. 30p. diagrs., photos., 2 tabs. (NACA TN 3218. Formerly RM L50L18)

External-drag and pressure-recovery data are presented for the NACA 1-40-250 nose inlet. The tests were made using rocket-propelled models in free flight at Mach numbers from 0.9 to 1.8. The Reynolds number based on body diameter varied from 4×10^6 to 10×10^6.

NACA TN 3384

EFFECT OF HYDROCARBON STRUCTURE ON REACTION PROCESSES LEADING TO SPONTANEOUS IGNITION. Donald E. Swarts and Charles E. Frank, University of Cincinnati. July 1955. 23p. diagrs., 6 tabs. (NACA TN 3384)

The present study compares the reaction processes of other aliphatic hydrocarbons with those of the heptane and isooctane previously studied. A study of the behavior of olefins and some exploratory work on the effect of the ratio of surface to volume on the extent of oxidation in the early stages was also included.

NACA TN 3419

NACA MODEL INVESTIGATIONS OF SEAPLANES IN WAVES. John B. Parkinson. (Presented at Conference on Ships and Waves, Stevens Institute of Technology, Oct. 25-27, 1954) July 1955. 28p. diagrs., photos. (NACA TN 3419)

The models, apparatus, and instrumentation developed for investigations of the rough-water characteristics of seaplanes in the Langley tanks are described briefly. The results of several investigations to improve these characteristics are combined and summarized. The large effect of waves in take-off resistance is illustrated. The general relationship of the measured quantities of importance to wave length and height are also illustrated.

NACA TN 3422

NOISE SURVEY OF A 10-FOOT FOUR-BLADE TURBINE-DRIVEN PROPELLER UNDER STATIC CONDITIONS. Max C. Kurbjun. July 1955. 25p. diagrs., photo. (NACA TN 3422)

Overall sound-level measurements and tape recordings of the noise emitted from a 10-foot-diameter, four-blade propeller mounted on a propeller-research vehicle have been made under static conditions at stations spaced on a 75-foot-radius circle about the propeller. The tape recordings were analyzed to obtain the frequency spectra at each station and comparisons of the results are made with theory. The effects of microphone position above the ground are also given.

NACA TN 3460

TABLES OF COEFFICIENTS FOR THE ANALYSIS OF STRESSES ABOUT CUTOUTS IN CIRCULAR SEMIMONOCOQUE CYLINDERS WITH FLEXIBLE RINGS. Harvey G. McComb, Jr. and Emmet F. Low, Jr. July 1955. 98p. diagrs., 30 tabs. (NACA TN 3460)

Tables of coefficients are presented which facilitate the stress analysis of circular semimonocoque cylinders with cutouts by the method published in NACA TN 3200. When the values of two simple structural parameters are known, use of these coefficients enables shear flows and stringer loads in the neighborhood of a cutout to be calculated. The effect of bending flexibility of the rings in their planes has been taken into consideration in the computation of the coefficients. Included as a limiting case are the tables from NACA TN 3200 which were computed on the assumption that there is no distortion of the rings in their planes.

NACA TN 3462

TENSILE PROPERTIES OF 7075-T6 AND 2024-T3 ALUMINUM-ALLOY SHEET HEATED AT UNIFORM TEMPERATURE RATES UNDER CONSTANT LOAD. George J. Heimerl and John E. Inge. July 1955. 46p. diagrs., photos., 4 tabs. (NACA TN 3462)

Results are presented of tests to determine the effect of heating at uniform temperature rates from 0.2° to 100° F per second on the tensile properties of 7075-T6 (75S-T6) and 2024-T3 (24S-T3) aluminum-alloy sheet under constant-load conditions. Yield and rupture stresses, obtained under rapid-heating conditions, are compared with results of elevated-temperature stress-strain tests for 1/2-hour exposure. Master yield- and rupture-stress curves based on a linear temperature-rate parameter are presented. Yield and rupture stresses and temperatures may be predicted by means of master curves and the parameter.

NACA TN 3465

THEORETICAL INVESTIGATION OF FLUTTER OF TWO-DIMENSIONAL FLAT PANELS WITH ONE SURFACE EXPOSED TO SUPERSONIC POTENTIAL FLOW. Herbert C. Nelson and Herbert J. Cunningham. July 1955. 60p. diagrs., tab. (NACA TN 3465)

A Rayleigh type analysis is used to treat the flutter of a two-dimensional flat panel supported at its leading and trailing edges and subjected to a middle-

plane tensile force, with a supersonic stream over its upper surface and still air below. Numerical results in the form of stability boundaries are presented for determining some effects of number of modes, Mach number, densities of the supersonic stream and still air, panel mass and stiffness, edge fixity, structural damping, and middle-plane tensile force.

NACA TN 3466

AN INVESTIGATION OF THE DISCHARGE AND DRAG CHARACTERISTICS OF AUXILIARY-AIR OUTLETS DISCHARGING INTO A TRANSONIC STREAM. Paul E. Dewey and Allen R. Vick. July 1955. 38p. diagrs., photos. (NACA TN 3466)

The aerodynamic characteristics of auxiliary-air outlets of rectangular cross section discharging into a transonic stream have been investigated. The effects of aspect ratio, inclination, curvature, and recess depth upon the discharge coefficients have been determined for thin-plate and ducted-approach outlets. Surface pressure distributions in the vicinity of ducted outlets and vent pressures with no discharge are also presented. In addition, force coefficients have been measured for a few of the ducted-approach models.

NACA TN 3468

EFFECTS OF SWEEP ON THE MAXIMUM-LIFT CHARACTERISTICS OF FOUR ASPECT-RATIO-4 WINGS AT TRANSONIC SPEEDS. Thomas R. Turner. July 1955. 25p. diagrs. (NACA TN 3468. Formerly RM L50H11)

An investigation at transonic speeds has been made to determine the effect of wing sweep on the maximum lift characteristics of a series of wings having an aspect ratio of 4, a taper ratio of 0.6, and the quarter-chord line swept back 0°, 35°, 45°, and 60°. The Mach number varied from 0.61 to 1.20 with a Reynolds number variation from 380,000 to 460,000. Lift data are presented from approximately zero lift to beyond maximum lift. Drag and pitching-moment data are also presented.

NACA TN 3472

FLOW STUDIES ON FLAT-PLATE DELTA WINGS AT SUPERSONIC SPEED. William H. Michael, Jr. July 1955. 40p. diagrs., photos. (NACA TN 3472)

An experimental study has been made to investigate some aspects of the nature of the flow around flat-plate delta wings. Vapor-screen, pressure-distribution, and ink-flow studies were made at a Mach number of 1.9 on a series of semispan delta-wing models with slender wedge airfoil sections and very sharp leading edges. The models had semi-apex angles ranging from 5° to 31.75°.

NACA TN 3509

A STUDY OF BOUNDARY-LAYER TRANSITION AND SURFACE TEMPERATURE DISTRIBUTIONS AT MACH 3.12. Paul F. Brinich. July 1955. 39p. diagrs., photo. (NACA TN 3509)

Surface temperature distributions and high-speed schlieren motion pictures were used to study transition with and without single roughness elements on a hollow cylinder at various wind-tunnel Reynolds numbers. Increasing the sharpness of the leading edge increased the abruptness of the recovery temperature rise near the transition point and decreased the transition Reynolds number. Single roughness elements in the laminar boundary layer moved transition upstream and produced slight local changes in temperature distributions. Roughness elements in transitional and turbulent boundary layers produced large perturbations in temperature distributions.

NACA TN 3511

EXTRAPOLATION TECHNIQUES APPLIED TO MATRIX METHODS IN NEUTRON DIFFUSION PROBLEMS. Robert R. McCready. July 1955. 32p. diagrs. (NACA TN 3511)

An iterative scheme is developed for the matrix solution of the type of characteristic-value problem arising from homogeneous linear equations. The scheme is shown to minimize a suitable form at each step. Extrapolation techniques for speeding convergence are developed and refined. An example from nuclear-reactor theory is presented.

NACA TN 3512

EFFECT OF SOME SELECTED HEAT TREATMENTS ON THE OPERATING LIFE OF CAST HS-21 TURBINE BLADES. Francis J. Clauss, Floyd B. Garrett and John W. Weeton. July 1955. 39p. diagrs., photos. (NACA TN 3512)

Effects of heat treatment depend upon initial microstructure of cast blades. Blades from one manufacturer performed best in the as-cast condition; blades from a second manufacturer performed best after aging 48 hours at 1500° F. Solution treatments at 2050° F and above often caused damage by eutectic melting. Before the full benefits of heat treatment can be realized, casting conditions must be controlled to produce uniform structures with finely distributed carbides and a minimum of interdendritic segregation.

LOADING CONDITIONS OF TAILED AIRCRAFT IN LONGITUDINAL MANOEUVRES. T. Czaykowski. February 1955. 80p. diagrs., tab. (RAE Structures 177)

This analysis of aircraft response and loading conditions in symmetrical maneuvers is based on the theory of aircraft response to elevator induced longitudinal maneuvers. Basic response functions have been derived for the chosen, exponential type of elevator motion, and from these, general expressions have been obtained for various derived response quantities, such as tail plane loads, elevator hinge moments, normal accelerations at the tail, etc. A computational method is given in the appendix which allows the evaluation of the complete time histories of response quantities or, alternatively, their significant maxima. The simplifying assumptions underlying the analysis are critically reviewed and possible limitations of the method are discussed.

Nat. Gas Turbine Establishment (Gt. Brit.)
THE PERFORMANCE TESTING OF AIRCRAFT GAS TURBINE COMBUSTION CHAMBERS UNDER ALTITUDE CONDITIONS. P. Martin and M. V. Herbert. November 1954. 24p. diagrs., 3 tabs. (NGTE Memo. M. 231)

Combustion chamber test conditions chosen according to Ashwood's method of standardization are too limited for current general use. The inlet conditions found in existing engines have been investigated, and the overall range of temperature and pressure has been defined. A standard division of this range is proposed. The constancy of $\frac{Q\sqrt{T_2}}{p_2}$ over the subsonic working range of an engine enables air mass flow to be determined for any combination of temperature and pressure, and variation of this parameter at supersonic speeds is considered. Test results may be presented as a chamber characteristic, offering easy comparison between individual combustion systems.

Aeronautical Research Council (Gt. Brit.)
COMPRESSOR CASCADE FLUTTER TESTS - 20° CAMBER BLADES, MEDIUM AND HIGH STAGGER CASCADES. D. A. Kilpatrick and J. Ritchie. 1955. 19p. diagrs., photos. (ARC CP 187)

The tests reported show the existence of three main zones of flutter at high stress: stalling flutter, shock-stalling flutter, and choking flutter. These zones are similarly located (with reference to the aerodynamic characteristics) for both the medium and the high stagger cascades tested, and they extend over a wide range of incidence. Good correlation between the zones of flutter and the experimentally measured blade force derivatives, with respect to Mach number and incidence, has been obtained. More experimental data are, however, required before a quantitative analysis of the problem can be achieved.

N-38252*

Aeronautical Research Council (Gt. Brit.) SOME VISUAL OBSERVATIONS OF THE FLOW OVER A SWEPT-BACK WING IN A WATER TUNNEL, WITH PARTICULAR REFERENCE TO HIGH INCIDENCES. N. C. Lambourne and P. S. Pusey. 1955. 20p. diagrs., photos. (ARC CP 192)

These tests were restricted to low Reynolds numbers (about 10^5 based on mean chord). Visualization was effected by two techniques, namely, (1) the addition of small aluminum particles to the water, and (2) the introduction of air into the stream close to the model. In addition, the surface patterns produced by the flow after the wing had been coated with oil were obtained. Attention has been concentrated on the flow that exists at high incidence which is characterized by a flat horn-shaped region of separated flow expanding in extent over the suction surface from a position inboard near the leading edge. A part-span trailing vortex has been revealed and appears to be a continuation of a discrete vortex situated in the separated region.

Research Abstracts

NO. 88 AUGUST 24, 1955

CURRENT NACA REPORTS

NACA Rept. 1176

DETERMINATION OF MEAN CAMBER SURFACES FOR WINGS HAVING UNIFORM CHORDWISE LOADING AND ARBITRARY SPANWISE LOADING IN SUBSONIC FLOW. S. Katzoff, M. Frances Faison and Hugh C. DuBose. 1954. ii, 17p. diagrs., tab. (NACA Rept. 1176. Formerly TN 2908)

Methods involving integrations around the wing boundary are presented for computing mean camber surfaces to support uniform chordwise loading, with either uniform or nonuniform spanwise loading, in subsonic flow. For polygonal wings with uniform area loading, analytical expressions are developed for both the slopes and the ordinates of the mean camber surfaces. Mean camber surfaces of several calculated wings are shown.

NACA Rept. 1178

CALIBRATION OF STRAIN-GAGE INSTALLATIONS IN AIRCRAFT STRUCTURES FOR THE MEASUREMENT OF FLIGHT LOADS. T. H. Skopinski, William S. Aiken, Jr. and Wilber B. Huston. 1954. ii, 29p. diagrs., 10 tabs. (NACA Rept. 1178. Formerly TN 2993; RM L52G31)

A general procedure is developed for calibrating strain-gage installations in aircraft structures for application to flight measurements of loads. The basic procedure can be modified as necessary to suit the requirements of any particular structure. The application of the procedure is illustrated by results for two typical structures.

NACA Rept. 1183

SUPERSONIC FLOW PAST OSCILLATING AIRFOILS INCLUDING NONLINEAR THICKNESS EFFECTS. Milton D. Van Dyke. 1954. ii, 17p. diagrs. (NACA Rept. 1183. Formerly TN 2982)

A solution to second order in thickness is derived for harmonically oscillating two-dimensional airfoils in supersonic flow. For slow oscillations of an arbitrary profile, the result is found as a series including the third power of frequency. For arbitrary frequencies, the method of solution for any specific profile is indicated, and the explicit solution derived for a single wedge. Nonlinear thickness effects are found generally to reduce the torsional damping, and so enlarge the range of Mach numbers within which torsional instability is possible.

NACA Rept. 1184

THE NORMAL COMPONENT OF THE INDUCED VELOCITY IN THE VICINITY OF A LIFTING ROTOR AND SOME EXAMPLES OF ITS APPLICATION. Walter Castles, Jr. and Jacob Henri De Leeuw, Georgia Institute of Technology. 1954. ii, 15p. diagrs., 3 tabs. (NACA Rept. 1184. Formerly TN 2912)

A method is presented for computing the approximate values of the normal component of the induced velocity at points in the flow field of a lifting rotor. Tables and graphs of the relative magnitudes of the normal component of the induced velocity are given for selected points in the longitudinal plane of symmetry of the rotor and on the lateral rotor axis. A method is also presented for using the tables and graphs to determine the interference induced velocities arising from the second rotor of a tandem- or side-by-side-rotor helicopter and the induced flow angle at a horizontal tail plane.

NACA Rept. 1188

ON THE USE OF THE INDICIAL FUNCTION CONCEPT IN THE ANALYSIS OF UNSTEADY MOTIONS OF WINGS AND WING-TAIL COMBINATIONS. Murray Tobak. 1954. iii, 43p. diagrs. (NACA Rept. 1188)

The concept of indicial aerodynamic functions is applied to the analysis of the short-period pitching mode of aircraft. By the use of simple physical relationships associated with the indicial-function concept, qualitative studies are made of the separate effects on the damping in pitch of changes in Mach number, aspect ratio, plan-form shape, and frequency. The concept is further shown to be of value in depicting physically the induced effects on a tail surface which follows in the wake of a starting forward surface. Considerable effort is devoted to the development of theoretical techniques whereby the transient response in lift at the tail to the wing wake may be estimated. Numerical results for several representative cases are presented, and these are analyzed to reassess the importance of the contribution to the rotary damping moment of the interference lift at the tail.

NACA Rept. 1194

A STUDY OF HYPERSONIC SMALL-DISTURBANCE THEORY. Milton D. Van Dyke. 1954. ii, 21p. diagrs. (NACA Rept. 1194. Formerly TN 3173)

The small-disturbance equations are derived for inviscid flow past thin bodies at high supersonic speeds. Reinterpreted, they apply throughout the

supersonic range. The theory is used to find pressures on cones and wedges, initial gradients on ogives, and initial pressure curvatures on ogives of revolution. Additional approximations from existing theories are discussed.

NACA Rept. 1196

AN ANALYTICAL STUDY OF THE EFFECT OF AIRPLANE WAKE ON THE LATERAL DISPERSION OF AERIAL SPRAYS. Wilmer H. Reed, III. 1954. ii, 16p. diagrs., 3 tabs. (NACA Rept. 1196. Formerly TN 3032)

An analysis is made to determine the trajectories and deposit of aerial spray droplets which are issued into the air disturbances generated by an agricultural airplane. Various nozzle arrangements and droplet-size spectra are considered with a view to improving the uniformity and effective width of the deposit.

NACA RM 55F08

METAL-BONDING ADHESIVES FOR HIGH-TEMPERATURE SERVICE. John M. Black and R. F. Blomquist, Forest Products Laboratory. July 1955. 22p. tab. (NACA RM 55F08)

Results of an investigation made for the purpose of developing a metal-bonding adhesive with improved heat-resistant properties are reported. The most promising results were obtained with a formulation of a phenol resin and an epoxy resin with certain heat stabilizers and catalysts. An improved straight epoxy-resin adhesive that has superior strength properties at 250° to 300° F compared with any other known epoxy-resin adhesive formulation is also reported.

NACA TN 3298

A LOW-DENSITY WIND-TUNNEL STUDY OF SHOCK-WAVE STRUCTURE AND RELAXATION PHENOMENA IN GASES. F. S. Sherman, University of California. July 1955. 83p. diagrs., photos., 2 tabs. (NACA TN 3298)

The profiles and thicknesses of normal shock waves of moderate strength were determined in terms of the variation of the equilibrium temperature of an insulated transverse cylinder in free-molecule flow. The shock waves were produced in a steady state in the jet of a low-density wind tunnel at initial Mach numbers of 1.72 and 1.82 in helium and 1.78, 1.85, 1.90, 1.98, 3.70, and 3.91 in air. The shock thickness was determined from the maximum slope of the cylinder temperature profile. The experimental shock profiles are compared with various theoretical predictions.

NACA TN 3470

GUST-TUNNEL INVESTIGATION OF THE EFFECT OF A SHARP-EDGE GUST ON THE FLAPWISE BLADE BENDING MOMENTS OF A MODEL HELICOPTER ROTOR. Domenic J. Maglieri and Thomas D. Reisert. August 1955. 24p. diagrs., photos. (NACA TN 3470)

Preliminary investigations have been made in the Langley gust tunnel to determine the effects of a sharp-edge vertical gust on the blade flapwise vibratory bending moments of small model rotors having either fixed-at-root or teetering blades. Both rotor configurations were tested up to a tip-speed ratio of about 0.35. The results for simulated forward flight indicate that the effect of the gust on the maximum vibratory bending moments is of less importance for the teetering rotor than for the fixed-at-root rotor. Increasing the rotor speed decreases the magnitude of the vibratory bending moments resulting from a given gust. At a given rotor speed, the magnitude of the vibratory components due to the gust increases with increasing tip-speed ratio. Increasing the rotor speed at a constant forward velocity decreases the maximum vibratory bending moments for all conditions tested.

NACA TN 3471

THEORETICAL ANALYSES TO DETERMINE UNBALANCED TRAILING-EDGE CONTROLS HAVING MINIMUM HINGE MOMENTS DUE TO DEFLECTION AT SUPERSONIC SPEEDS. Kennith L. Goin. August 1955. 52p. diagrs., tab. (NACA TN 3471. Formerly RM L51F19)

Theoretical analyses have been made to determine the plan forms of unbalanced trailing-edge flap-type controls having minimum hinge moments due to deflection and requiring minimum work to overcome the hinge moments due to deflection at supersonic speeds. Ratios of lift and rolling moment to hinge moment and lift and rolling moment to deflection work at fixed values of lift and rolling effectiveness were used as bases for the analyses. The effects of control plan form, control location, and Mach number have been considered.

NACA TN 3473

EFFECTS OF SWEEP AND ANGLE OF ATTACK ON BOUNDARY-LAYER TRANSITION ON WINGS AT MACH NUMBER 4.04. Robert W. Dunning and Edward F. Ulmann. August 1955. 31p. diagrs., photos. (NACA TN 3473)

Wind-tunnel tests were conducted at Mach number 4.04 to determine the effects of leading-edge sweep, angle of attack, and leading-edge thickness on the boundary-layer transition on flat-plate wings. In addition, some results were obtained on wings having rounded leading-edge sections. Transition points were determined for angles of attack up to

20° and for leading-edge sweep angles from 0° to 72°. A correlation has been obtained, for the present data, of the effects of leading-edge sweep and angle of attack on boundary-layer transition on plane surfaces when the equivalent stagnation pressure (stagnation pressure calculated from the local static pressure and the local Mach number normal to the leading-edge) and the rate of change of the transition Reynolds number with equivalent stagnation pressure are considered.

NACA TN 3482

SUPPLEMENTARY CHARTS FOR ESTIMATING PERFORMANCE OF HIGH-PERFORMANCE HELICOPTERS. Robert J. Tapscott and Alfred Gessow. July 1955. 31p. diagrs. (NACA TN 3482)

Charts published in NACA TN 3323 for estimating the performance of high-performance helicopters were applicable to rotors having hinged rectangular blades with a linear twist of -8°. Supplementary charts are presented herein covering twists of 0° and -16°.

NACA TN 3484

ON SPECTRAL ANALYSIS OF RUNWAY ROUGHNESS AND LOADS DEVELOPED DURING TAXIING. John C. Houbolt, James H. Walls and Robert F. Smiley. July 1955. 9p. diagrs. (NACA TN 3484)

The application of the technique of generalized harmonic analysis as a means for determining airplane taxiing loads is considered in a cursory manner. Some results on runway roughness are reviewed and some results obtained from taxiing tests of a large airplane are given. An elementary extrapolation of results for low taxiing velocities to higher velocities is shown to be conservative. Also, oleo-strut friction is shown to be a very important factor. With regard to the load-prediction phase of taxiing loads by spectral techniques, much additional work is required, especially with respect to the treatment of the transfer function.

NACA TN 3487

ACOUSTIC RADIATION FROM TWO-DIMENSIONAL RECTANGULAR CUTOUTS IN AERODYNAMIC SURFACES. K. Krishnamurty, California Institute of Technology. August 1955. 33p. diagrs., photos. (NACA TN 3487)

The acoustic radiation from two-dimensional rectangular cavities cut into a flat surface was investigated by schlieren, hot-wire, and optical interferometric techniques. The relation of the frequency, as measured in the gap by a hot-wire, to the gap breadth at a particular Mach number and free-stream temperature is shown. The intensity of the radiation was measured by means of an optical interferometer.

NACA TN 3488

SOME MEASUREMENTS OF FLOW IN A RECTANGULAR CUTOUT. Anatol Roshko, California Institute of Technology. August 1955. 21p. diagrs. (NACA TN 3488)

The flow in a rectangular cavity, or slot, in the floor of a wind tunnel is described by the results of pressure and velocity measurements. Pressure distributions on the cavity walls as well as measurements of friction are presented. The effects of varying depth-breadth ratio are shown.

NACA TN 3507

PRACTICAL CONSIDERATIONS IN SPECIFIC APPLICATIONS OF GAS-FLOW INTERFEROMETRY. Walton L. Howes and Donald R. Buchele. July 1955. ii, 95p. diagrs., photos. (NACA TN 3507)

By extending the analysis in NACA TN 3340, equations which simultaneously account for refraction and corner effects are derived for evaluating one-dimensional density fields from optical interferograms. The random error in measuring fringe shifts is determined. Spurious surface phenomena are discussed and a simple method for model alinement is described. A method for determining the density at a surface is described. Systematic and random errors are computed for three representative experimental situations, namely, boundary layers associated with supersonic and subsonic flows along flat plates and free convection of heat from a horizontal cylinder. Reasons for discrepancies between theory and experiment are offered.

NACA TN 3515

ANALYSIS OF TWO-DIMENSIONAL COMPRESSIBLE-FLOW LOSS CHARACTERISTICS DOWNSTREAM OF TURBOMACHINE BLADE ROWS IN TERMS OF BASIC BOUNDARY-LAYER CHARACTERISTICS. Warner L. Stewart. July 1955. 48p. diagrs. (NACA TN 3515)

Equations are derived for obtaining compressible-flow boundary-layer characteristics for a simple power velocity profile. Loss coefficients at the trailing edge and after mixing are then obtained in terms of these boundary-layer characteristics. This analysis is used to study the general effect of compressibility on blade-exit loss characteristics, the significance of mixing downstream of the blade row, and the effect of trailing-edge thickness on overall loss coefficients.

NACA TN 3516

SUMMARY EVALUATION OF TOOTHED-NOZZLE ATTACHMENTS AS A JET-NOISE-SUPPRESSION DEVICE. Warren J. North. July 1955. 19p. diagrs., photo. (NACA TN 3516)

Toothed attachments to a full-scale turbojet nozzle

were investigated for possible jet-noise reduction and thrust penalty. The attachments caused slight reductions in total sound power that are insignificant when evaluated in terms of engine thrust losses and aircraft payload penalty. At the reduced thrust levels obtained with the toothed nozzles, corresponding sound power reductions could be realized by throttling the standard turbojet engine. Sound pressure levels were reduced behind the engine but were increased elsewhere. A typical resident in the airport neighborhood would hear increased loudness in the middle frequencies; however, the resulting overall auditory effect is considered to be negligible.

NACA TN 3518

ROTATING-STALL CHARACTERISTICS OF A ROTOR WITH HIGH HUB-TIP RADIUS RATIO. Eleanor L. Costilow and Merle C. Huppert. August 1955. 59p. diagrs., photos. (NACA TN 3518)

The rotating-stall characteristics of a 0.9 hub-tip ratio rotor are investigated. The test setup approximates the two-dimensional model upon which recent theories have been based. Measurements of pressure, temperature, and flow fluctuations during stalled operation are reported. Experimental stall-propagation rates are compared with those predicted by theory.

NACA TN 3520

FLAME PROPAGATION LIMITS OF PROPANE AND n-PENTANE IN OXIDES OF NITROGEN. Riley O. Miller. August 1955. 29p. diagrs., 3 tabs. (NACA TN 3520)

Flame propagation limits with propane and n-pentane in oxides of nitrogen were obtained at subatmospheric pressures in a 2-inch-diameter, 48-inch-length tube. Three oxidants were investigated; namely, nitric oxide NO, nitrogen tetroxide N_2O_4, and a nearly equimolar mixture of these two oxides. Flames propagate through all these mixtures with the composition limits occurring at equivalence ratios of roughly 1/3 and 3. The minimum propagation pressure of the fuel-NO mixtures in the 2-inch-diameter tube were appreciably greater than that of the fuel-N_2O_4 mixtures. In general, the data attest to the relative chemical stability of NO in the hydrocarbon flames.

NACA TN 3521

A COMPARISON OF THE MEASURED AND PREDICTED LATERAL OSCILLATORY CHARACTERISTICS OF A 35° SWEPT-WING FIGHTER AIRPLANE. Walter E. McNeill and George E. Cooper. August 1955. 22p. diagrs., photo., 3 tabs. (NACA TN 3521. Formerly RM A51C28)

Flight measurements of the lateral oscillatory characteristics were obtained at altitudes of 10,000 and 35,000 feet for an over-all Mach number range from 0.41 to 1.04. Period, time to damp to half amplitude, and ratio of angle-of-bank amplitude to angle-of-sideslip amplitude, $|\varphi| / |\beta|$, are presented as functions of Mach number for each test altitude, and are compared with values computed from wind-tunnel data and estimated stability derivatives.

NACA TN 3540

A REEVALUATION OF GUST-LOAD STATISTICS FOR APPLICATIONS IN SPECTRAL CALCULATIONS. Harry Press and May T. Meadows. August 1955. 19p. diagrs. (NACA TN 3540)

The available information on the spectrum of atmospheric turbulence is briefly reviewed. On the basis of these results, a method is developed for the conversion of available gust statistics normally given in terms of counts of gust peaks into a form appropriate for use in spectral calculation. The fundamental quantity for this purpose appears to be the probability distribution of the root-mean-square gust velocity. Estimates of the variation of this distribution with altitude and weather condition are also derived from available gust statistics.

DECLASSIFIED NACA REPORTS

NACA RM A51G13

AERODYNAMIC CHARACTERISTICS OF THE NACA RM-10 RESEARCH MISSILE IN THE AMES 1- BY 3-FOOT SUPERSONIC WIND TUNNEL NO. 2 - PRESSURE AND FORCE MEASUREMENTS AT MACH NUMBERS OF 1.52 AND 1.98. Edward W. Perkins, Forrest E. Gowen, and Leland H. Jorgensen. September 1951. 37p. diagrs. (NACA RM A51G13) (Declassified from Confidential, 7/20/55)

The pressure distribution along the body of zero angle of attack and around the body for various longitudinal stations and for angles of attack to 15° are presented. These data are compared with the method of characteristics and with linear and second-order theories. Aerodynamic coefficients for the body alone and the body-tail combination were obtained at Reynolds numbers, based on model length, of 8.6 and 17.4 millions. The body-alone aerodynamic coefficients are compared with the theory of NACA RM A9I26 and with potential theory.

NACA RM A55C07

FLIGHT TESTS OF LEADING-EDGE AREA SUCTION ON A FIGHTER-TYPE AIRPLANE WITH A 35° SWEPTBACK WING. Richard S. Bray and Robert C. Innis. June 1955. 30p. diagrs., photos., tab. (NACA RM A55C07) (Declassified from Confidential, 7/20/55)

Flight measurements made of the low-speed lift characteristics of an F-86 airplane equipped with a porous leading-edge installation confirmed the results obtained from wind-tunnel tests of a similar installation. Large gains in maximum lift coefficient were obtained. Stalling characteristics were tolerable to good. The porous leading edge had no marked effect on the operational performance of the airplane.

NACA RM E51F28

SOME EFFECTS OF BLADE TRAILING-EDGE THICKNESS ON PERFORMANCE OF A SINGLE-STAGE AXIAL-FLOW COMPRESSOR. J. J. Moses and G. K. Serovy. October 1951. 14p. diagrs., tab. (NACA RM E51F28) (Declassified from Confidential, 7/20/55)

A set of modified NACA 65-series blower blades designed for axial inlet velocity, high inlet Mach number, and high blade loading was investigated for trailing-edge thicknesses of 0.015, 0.030, and 0.045 inch to determine the effect of trailing-edge thickness on single-stage axial-flow-compressor performance. Trailing-edge thickness effects were small except at the highest tip speed investigated (915 ft/sec). Trailing-edge thicknesses up to 30 percent of maximum blade thickness were used without sacrifice of performance of NACA 65-series blades.

NACA RM E52K13

PRELIMINARY INVESTIGATION IN J33 TURBOJET ENGINE OF SEVERAL ROOT DESIGNS FOR CERAMAL TURBINE BLADES. George C. Deutsch, Andre J. Meyer, Jr., and William C. Morgan. January 1953. 24p. diagrs., photos., 2 tabs. (NACA RM E52K13) (Declassified from Confidential, 7/20/55)

The practicability of using ceramals with comparatively low strategic material content for the blades of aircraft turbines was determined in an experimental investigation. Four blade root configurations were examined. The most favorable results were obtained for ceramal turbine blades with single serration interlock and dovetail root configurations. Six of the interlock type were operated in a J33-A-33 engine for 68 hours, 23 minutes at rated service speed and six of the dovetail type were operated for 58 hours, 28 minutes at rated speed. This result confirms the conclusions of previous static design studies.

NACA RM E53B27

AN INVESTIGATION OF HIGH-FREQUENCY COMBUSTION OSCILLATIONS IN LIQUID-PROPELLANT ROCKET ENGINES. Adelbert O. Tischler, Rudolph V. Massa, and Raymond L. Mantler. June 1953. 37p. diagrs., photos. (NACA RM E53B27) (Declassified from Confidential, 7/20/55)

An experimental investigation of high-frequency combustion oscillations (screaming) was conducted with a 100-pound-thrust acid-hydrocarbon rocket engine and a 500-pound-thrust oxygen-fuel rocket engine. The oscillation frequencies could be correlated as a linear function of the parameter C^*/L, where C^* is the experimentally measured characteristic velocity and L is the combustion-chamber length. The tendency of the engines to scream increased as chamber length was increased. With engine configurations that normally had a low efficiency, screaming resulted in increased performance; at the same time, a five to tenfold increase in heat-transfer rate occurred. It was possible, however, to achieve good performance without screaming.

NACA RM E53G02

PRELIMINARY INVESTIGATION OF SEVERAL ROOT DESIGNS FOR CERMET TURBINE BLADES IN TURBOJET ENGINE. II - ROOT DESIGN ALTERATIONS. A. J. Meyer, Jr., G. C. Deutsch, and W. C. Morgan. October 1953. 34p. photos., diagrs., tab. (NACA RM E53G02) (Declassified from Confidential, 7/20/55)

Twelve engine evaluation tests of cermet turbine blades are reported herein. The first five runs were similar to the 10 engine tests reported previously. The cermet blades were then redesigned on the basis of information gained during the earlier runs. The profile of the root was changed; the airfoil was relocated on the platform and root; the root center line was rotated with respect to the turbine axis; and an attempt was made to improve the blade material. These alterations primarily accomplished a reduction in root bending stresses and resulted in greatly increased blade life. The modified blades were operated under increased power output from the engine and were subjected to cyclic conditions between take-off speed and idling speed.

NACA RM E53L15b

PRELIMINARY INVESTIGATION OF SEVERAL TARGET-TYPE THRUST-REVERSAL DEVICES. Fred W. Steffen, H. George Krull, and Carl C. Ciepluch. March 1954. 43p. diagrs., tab. (NACA RM E53L15b) (Declassified from Confidential, 7/20/55)

Thrust-reversal performance of several basic target-type jet deflectors of various size and with various modifications was obtained with unheated air over a range of exhaust-nozzle pressure ratios from 1.7 to 3.0. Reversed thrusts up to 58 percent were achieved. Maximum, or near maximum, reversal

for any deflector occurred at a spacing which was mechanically feasible and which did not affect nozzle air flow. Two easily retractable deflectors, a simple hemisphere and a double-skin hemisphere, the latter designed to control reversed jet direction, were investigated while installed on a model of a turbojet engine tail pipe and cowling assembly. Reversal produced by the installation with either deflector was found to be about 40 percent at a nozzle pressure ratio of 2.0. With the simple hemisphere, 50 percent of the available thrust was lost through insufficient turning and 11 percent was lost through air-flow reduction, shock, and friction.

NACA RM L7C25

AERODYNAMIC MEASUREMENTS MADE DURING NAVY INVESTIGATION OF HUMAN TOLERANCE TO WIND BLASTS. Donald L. Loving. March 11, 1947. 34p. diagrs., photos., 2 tabs. (NACA RM L7C25) (Declassified from Confidential, 6/10/55)

Tests were made to obtain direct evidence of the forces involved when the human head is suddenly thrust into a rapidly moving air stream, as is the case in bail-outs from aircraft at high speeds, and also to determine the maximum speed considered safe for the unprotected face to be exposed to wind blasts. Included are the aerodynamic results of the pressure measurements over a dummy forehead and the air-blast forces on the unprotected heads tested as obtained through the use of a strain gage attached to the head rest of the test apparatus.

NACA RM L8G21

MEASUREMENTS OF THE CHORDWISE PRESSURE DISTRIBUTIONS OVER THE WING OF THE XS-1 RESEARCH AIRPLANE IN FLIGHT. De E. Beeler, Milton D. McLaughlin, and Dorothy C. Clift. August 4, 1948. 35p. diagrs., photo., tab. (NACA RM L8G21) (Declassified from Confidential, 7/20/55)

Presents results of chordwise pressure-distribution measurements at a section near the midspan of the left wing of the XS-1 research airplane with an 8-percent-thick wing for a Mach number range of 0.75 to 1.25 at a normal-force coefficient of about 0.33 and for normal-force coefficients up to 0.93 at a Mach number of about 1.16.

NACA RM L51F27

WATER LANDING INVESTIGATION OF A HYDRO-SKI MODEL AT BEAM LOADINGS OF 18.9 AND 4.4. Sidney A. Batterson. September 1951. 54p. diagrs., photos., tab. (NACA RM L51F27) (Declassified from Confidential, 7/20/55)

Presents results obtained from an investigation conducted in the Langley impact basin of a model having a flat rectangular planing surface, a pulled-up bow, and a simulated landing wheel. Runs were made at beam loading of 18.9 and 4.4. The results include plots showing the variation of the non-dimensional loads and motions with both the wetted length and flight-path angle.

NACA RM L54H09

DRAG MEASUREMENTS ON A 1/6-SCALE, FINLESS, STING-MOUNTED NACA RM-10 MISSILE IN FLIGHT AT MACH NUMBERS FROM 1.1 TO 4.04 SHOWING SOME REYNOLDS NUMBER AND HEATING EFFECTS. Robert O. Piland. October 1954. 20p. diagrs., photos. (NACA RM L54H09) (Declassified from Confidential, 7/20/55)

A 1/6-scale, finless NACA RM-10 missile, sting-mounted on a parent body, has been flight tested to a peak Mach number of 4.04. Measurements of total drag, base drag, and wall temperature were obtained. Reynolds numbers of 17×10^6 to 47×10^6, based on body length, corresponding to Mach numbers 1.07 to 4.04 were encountered. Total- and base-drag coefficients are correlated with wind-tunnel results. The base-pressure coefficients are also compared with calculations using Love's methods for the estimation of base pressures. The friction drag is estimated from test measurements and a calculated pressure drag and is compared with theory.

NACA RM L54I03

AN INVESTIGATION OF THE CHARACTERISTICS OF THE NACA RM-10 (WITH AND WITHOUT FINS) IN THE LANGLEY 11-INCH HYPERSONIC TUNNEL AT A MACH NUMBER OF 6.9. William D. McCauley and William V. Feller. November 1954. 37p. diagrs., photos. (NACA RM L54I03) (Declassified from Confidential, 7/20/55)

Pressure distributions on the body and force balance results for the NACA RM-10 with and without fins are presented for angles of attack from 0 to about 20° at $M = 6.9$. The experimental results are compared with the following theories: method of characteristics, Van Dyke's second-order theory, conical-shock two-dimensional expansion theory, Newtonian impact theory, Grimminger, Williams, and Young's correlation prediction, and linear theory. Interference between fins and body is discussed. The effect of Mach number on the components of zero-lift drag and of the pitching moment, center of pressure, and lift-curve slope at zero lift are presented.

NACA Rept. 1190

AXIAL-LOAD FATIGUE PROPERTIES OF 24S-T AND 75S-T ALUMINUM ALLOY AS DETERMINED IN SEVERAL LABORATORIES. H. J. Grover and W. S. Hyler, Battelle Memorial Institute, Paul Kuhn and Charles B. Landers, Langley Aeronautical Laboratory and F. M. Howell, Aluminum Company of America. 1954. ii, 25p. diagrs., photos., 7 tabs. (NACA Rept. 1190. Formerly TN 2928)

In the initial phase of an NACA program on fatigue research, axial-load tests on 24S-T3 and 75S-T6 aluminum-alloy sheet have been made at the Battelle Memorial Institute and at the Langley Aeronautical Laboratory of the NACA. The test specimens were polished and unnotched. The manufacturer of the material, the Aluminum Company of America, has made axial-load tests on 24S-T4 and 75S-T6 rod material. The test techniques used at the three laboratories are described in detail; the test results are compared with each other and with results obtained on unpolished sheet by the National Bureau of Standards.

NACA RM E55F09

PRELIMINARY PERFORMANCE DATA OF SEVERAL TAIL-PIPE-CASCADE-TYPE MODEL THRUST REVERSERS. James G. Henzel, Jr. and Jack G. McArdle. August 1955. 48p. diagrs., photos., tab. (NACA RM E55F09)

The performance of several tail-pipe-cascade-type-model thrust reversers was obtained with symmetrical and asymmetrical cascade blade shapes. One reverser with a symmetrical cascade-blade shape had a maximum reversed thrust ratio of 76 percent of full forward thrust. This reverser also had good thrust modulation characteristics. Another reverser but with an asymmetrical cascade blade shape had a maximum reversed thrust ratio of 90 percent of full forward thrust.

NACA TN 3467

EFFECT OF INTERACTION ON LANDING-GEAR BEHAVIOR AND DYNAMIC LOADS IN A FLEXIBLE AIRPLANE STRUCTURE. Francis E. Cook and Benjamin Milwitzky. August 1955. 75p. diagrs., 2 tabs. (NACA TN 3467)

The effects of interaction between a landing gear and a flexible airplane structure on the behavior of the landing gear and the loads in the structure have been studied by treating the equations of motion of the airplane and the landing gear as a coupled system, where the landing gear is considered to have nonlinear characteristics. Numerical examples, based on the characteristics of two large airplanes, show the effects of interaction on the loads in the landing gear and in the structure. The effects of neglecting interaction and using the landing-gear forcing function for a rigid body in a dynamic analysis of a flexible airframe are also discussed.

NACA TN 3474

RAPID RADIANT-HEATING TESTS OF MULTIWEB BEAMS. Joseph N. Kotanchik, Aldie E. Johnson, Jr., and Robert D. Ross. September 1955. 30p. diagrs., photos., tab. (NACA TN 3474)

Results are described of rapid-heating tests on four unloaded multiweb box beams. Temperature distributions and strains measured during a heating cycle are given. An analysis of the thermal stress required to cause buckling is in agreement with the experimentally observed results. A transient heating apparatus used in the tests and capable of producing heating rates up to 100 Btu/ft^2-sec is described.

NACA TN 3478

ON BOATTAIL BODIES OF REVOLUTION HAVING MINIMUM WAVE DRAG. Keith C. Harder and Conrad Rennemann, Jr. August 1955. 28p. diagrs., tab. (NACA TN 3478)

The problem of determining the shape of slender boattail bodies of revolution for minimum wave drag has been reexamined. It was found that minimum solutions for Ward's slender-body drag equation can exist only for the restricted class of bodies for which the rate of change of cross-sectional area at the base is zero. In order to eliminate this restriction, certain higher order terms must be retained in the drag equation and isoperimetric relations. The minimum problem for the isoperimetric conditions of given length, volume, and base area is treated as an example. According to Ward's drag equation, the resulting body shapes have slightly less drag than those determined by previous investigators.

NACA TN 3480

FREE-SPINNING-TUNNEL INVESTIGATION OF GYROSCOPIC EFFECTS OF JET-ENGINE ROTATING PARTS (OR OF ROTATING PROPELLERS) ON SPIN AND SPIN RECOVERY. James S. Bowman, Jr. August 1955. 21p. diagrs., photo., 2 tabs., 6 charts. (NACA TN 3480)

AVAILABLE ON LOAN ONLY.
ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

A rotating flywheel powered by a model airplane engine mounted on a model in the Langley 20-foot free-spinning tunnel was used to simulate the gyroscopic effects of jet-engine rotating parts (or of rotating propellers) on the erect spin and spin-recovery characteristics of a military attack airplane. The effects of flywheel rotation on the angle of attack, the rate of rotation in spins, and the number of turns required for recovery are presented for various control settings and for a range of loadings.

NACA TN 3483

AN ANALYSIS OF ACCELERATION, AIRSPEED, AND GUST-VELOCITY DATA FROM A FOUR-ENGINE TRANSPORT AIRPLANE IN OPERATIONS ON AN EASTERN UNITED STATES ROUTE. Thomas L. Coleman and Mary W. Fetner. September 1955. 20p. diagrs., 3 tabs. (NACA TN 3483)

Time-history data obtained by the NACA VGH recorder from one model of a four-engine civil transport airplane during operations on an eastern United States route are analysed to determine the magnitude and frequency of occurrence of gusts, gust accelerations, and the associated airspeeds. Comparison of the results with previously reported results indicates the gust-load history to be more severe than for two other similar operations involving other types of four-engine transports. The present airplane was operated in rough air at a higher percentage of its design speed than were the other airplanes and this condition was primarily responsible for the more severe load history for the operation.

NACA TN 3489

CONTRIBUTIONS ON THE MECHANICS OF BOUNDARY-LAYER TRANSITION. G. B. Schubauer and P. S. Klebanoff, National Bureau of Standards. September 1955. 31p. diagrs. (NACA TN 3489)

The manner in which flow in a boundary layer becomes turbulent was investigated on a flat plate at wind speeds generally below 100 feet per second. Hot-wire techniques were used, and many of the results are derived from oscillograms of velocity fluctuations in the transition region. The more familiar aspects of transition are discussed, and the facts discovered while studying the characteristics of artificially produced turbulent spots are presented.

NACA TN 3505

AN EXPERIMENTAL INVESTIGATION OF REGIONS OF SEPARATED LAMINAR FLOW. Donald E. Gault. September 1955. 65p. diagrs., photos., 4 tabs. (NACA TN 3505)

Results are given for an experimental investigation of regions of separated flow initiated by separation of the laminar boundary layer (laminar separation "bubbles"). Total- and static-pressure surveys, hot-wire anemometer observations, and detailed pressure-distribution measurements were made in regions of separated flow on two airfoils. The measurements were obtained for a wide range of angles of attack and for Reynolds numbers from 1.5 to 10 million. Some results on the effects of an increase in turbulence level of the free stream are also included.

NACA TN 3506

CRITERIONS FOR PREDICTION AND CONTROL OF RAM-JET FLOW PULSATIONS. William H. Sterbentz and John C. Evvard. August 1955. 60p. diagrs., photos. (NACA TN 3506. Formerly RM E51C27)

Results of a theoretical and experimental study of ram-jet diffuser flow pulsing, commonly referred to as a "buzz condition," with and without combustion are presented. The theoretical approach to the problem is a simplified treatment of the ram jet likened to act as a Helmholtz resonator. The theoretical resonance criterions reasonably predicted the occurrence of diffuser-flow pulsations.

NACA TN 3510

AN AUTOMATIC VISCOMETER FOR NON-NEWTONIAN MATERIALS. Ruth N. Weltmann and Perry W. Kuhns. August 1955. 34p. diagrs., photos., tab. (NACA TN 3510)

A concentric-cylinder rotational viscometer is described that can measure viscosities from 0.05 to 20,000 poises, program and record meaningful flow curves of rate of shear against shearing stress for most non-Newtonian materials, record time-torque curves, and produce dynamic flow measurements. A program feature provides for selecting (1) the maximum rate of shear up to 4000 sec^{-1}, (2) the time required to increase rotational speed from zero to the preset maximum, and (3) two sequences of rate of shear, which is varied automatically at a constant acceleration. Test data and curves are presented.

NACA TN 3565

CHEMICAL ACTION OF HALOGENATED AGENTS IN FIRE EXTINGUISHING. Frank E. Belles. September 1955. 28p. diagrs., 3 tabs. (NACA TN 3565)

The action of halogenated fire-fighting agents is discussed in terms of chain-breaking reactions between agent and active particles (atoms and free radicals). Literature data on flammability peaks of n-heptane-agent-air mixtures are roughly correlated by reactivities assigned to halogen and hydrogen atoms in agent molecules. The value of hydrogen in agents is discussed. A method for the estimation of rate constants for the reaction of agent with active particles is described, and the rate constant for methyl bromide is obtained. The result predicts the observed peak concentration of methyl bromide quite well. The assumed mechanism is consistent with the observed facts.

BRITISH REPORTS

Royal Aircraft Establishment (Gt. Brit.)
THE REPRESENTATION OF ENGINE AIRFLOW IN WIND TUNNEL MODEL TESTING. J. Seddon and L. F. Nicholson. May 1955. 38p. diagrs., photos. (RAE Tech. Note Aero 2371)

The problems of engine air-flow representation in wind-tunnel models are reviewed. Methods which have been used satisfactorily in low subsonic tunnels are described briefly. Special difficulties associated with testing at transonic speeds are noted. Techniques of special application to small supersonic tunnels are described in some detail. It is shown that there are reasons why the representation of jets may be more important at supersonic speeds than at subsonic speeds and a description is given of the RAE jet interference tunnel, which is designed for the study of some of the problems involved.

BOUNDARY LAYERS ON SWEPT WINGS: THEIR EFFECTS AND THEIR MEASUREMENT. D. Kuchemann. April 1955. 37p. diagrs. (RAE Tech. Note Aero 2370)

This is a brief review of some work which has been done mainly at the RAE in the field of three-dimensional boundary layers, in particular on swept wings. Theoretical results are briefly mentioned, and some examples of measured boundary layers are given to illustrate the various effects that can now be distinguished as being characteristic of swept wings. The lift reduction and the drag increment which result from the boundary layer in comparison with the values in inviscid flow are discussed; and some types of flow which may occur as a consequence of boundary-layer separation are described. In view of the importance of obtaining further experimental evidence, reference is made to the instrumentation needed for that purpose.

Royal Aircraft Establishment (Gt. Brit.)
THE USE OF PITOT TUBES IN THE MEASUREMENT OF LAMINAR BOUNDARY LAYERS IN SUPERSONIC FLOW. R. J. Monaghan. May 1955. 37p. diagrs., photos., 2 tabs. (RAE Tech.Note Aero 2369)

This note summarizes the results of some research on the laminar problem at the Royal Aircraft Establishment. It describes the various effects (real or apparent) of pitot size found in a series of measurements of laminar boundary layers in supersonic flow. These lead to errors in the values of displacement and momentum thickness calculated from the pitot measurements, but it seems that it may be possible to obtain the correct experimental values by applying a simple correction factor dependent only on the ratio of pitot diameter to boundary-layer thickness.

PRESSURE-CABIN DESIGN: A DISCUSSION OF SOME OF THE STRUCTURAL PROBLEMS INVOLVED, WITH SUGGESTIONS FOR THEIR SOLUTION. D. Williams. March 1955. 51p. diagrs., tab. (RAE Tech. Note Structures 155)

The structural factors governing the design of a pressure cabin are discussed with a view to indicating possible practical approaches.

N-38467*

Marine Aircraft Experimental Establishment (Gt. Brit.) FULL SCALE MEASUREMENT OF IMPACT LOADS ON A LARGE FLYING BOAT (SUNDERLAND MK. 5). PART III - DATA FOR IMPACTS ON MAIN STEP. R. Parker. August 1954. 37p. diagrs., 2 tabs. (MAEE F/Res/259)

The results of a series of full-scale impact tests on the hull of a Sunderland Mk. 5 flying boat at an all up weight of 50,000 lb were compared with an appropriate theory and discussed generally in a previous report. As discrepancies between this data and the theory were shown and explanation of this has not been forthcoming, this report presents complete time histories of a number of the actual measurements to permit comparison with other theories when such become available and application by empirical methods where appropriate.

N-38468*

Marine Aircraft Experimental Establishment (Gt. Brit.) INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS - HYDRODYNAMIC STABILITY. PART 18 - THE STABILITY AND SPRAY CHARACTERISTICS OF MODEL N. D. M. Ridland, J. K. Friswell, and A. G. Kurn. April 1955. 25p. diagrs., photos., 3 tabs. (MAEE F/Res/254)

In this report results are presented of limited tests on the hydrodynamic characteristics of Model N of the series, these tests being designed solely to provide information on the interactions of the different parameters relevant to the series. The model has a length-to-beam ratio of 13 (the forebody being 6 beams in length and the afterbody 7 beams), 4° forebody warp, an afterbody to forebody keel angle of 8°, and a straight transverse step with a step depth of 0.15 beams. The tests comprised the determination of longitudinal stability limits without slipstream at $C_{\Delta_0} = 2.75$ and an investigation of spray at this loading. A short discussion of the results is also included.

N-38469*

Marine Aircraft Experimental Establishment (Gt. Brit.) INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS - HYDRODYNAMIC STABILITY. PART 13 - THE EFFECT OF AFTERBODY ANGLE ON STABILITY AND SPRAY CHARACTERISTICS. D. M. Ridland. February 1955. 31p. diagrs., photos., 3 tabs. (MAEE F/Res/248)

The effects of afterbody angle on longitudinal stability, spray and directional stability characteristics, and elevator effectiveness are deduced from the results of tests on three models of the series which were alike in every major respect except that of afterbody angle. The models had afterbody angles of 4°, 6°, and 8°, respectively. It was found that increasing afterbody angle improved longitudinal stability characteristics considerably, both with and without disturbance, increased trim generally, gave a slight improvement in spray and directional stability characteristics, and increased elevator effectiveness. The best hydrodynamic configuration was that with the 8° afterbody angle.

THE USE OF NEGATIVE FEEDBACK FOR DERIVING SHARP LIMITS IN ELECTRONIC ANALOGUE COMPUTERS. M. Squires and P. R. Benyon. April 1955. 27p. diagrs. (RAE Tech. Note GW 361)

This note draws attention to improvements in electronic limiting action which results when standard limiting devices are enclosed with d-c amplifiers in negative feedback loops. Experiments in which a "high-gain" amplifier was used yielded limiters which were ideal to within practical limits of observation. Three types of limiter are recommended. In one the limiting characteristic of an output cathode follower forming part of the amplifier is used. In the remaining two, the high reverse resistance of diodes is used to give a single-sided and a two-sided limit, respectively.

HEAT TREATMENT AND TENSILE PROPERTIES OF A TITANIUM - 13-PERCENT MOLYBDENUM ALLOY. G. I. Lewis, J. I. M. Forsyth, and H. Brooks. March 1955. 10p. diagrs., photos. (RAE Tech. Note Met. 215)

Titanium - 13-percent molybdenum alloy strip 0.06 in. thick prepared from magnesium reduced titanium sponge and molybdenum strip by arc melting and hot and cold rolling had a strength of 48.6 tons/in.^{2} with 33-percent uniform and 37-percent total elongation after quenching from 825° C to retain the β phase. Strengths obtained by subsequent overaging in the $\alpha + \beta$ field at 500°-550° C ranged from 79.3 tons/in.^{2} with 6-percent elongation and $E = 15.5 \times 10^{6}$ lb/in.^{2} to 87.4 tons/in.^{2} with 4-percent elongation and $E = 15.9 \times 10^{6}$ lb/in.^{2}. Deformation in the quenched condition caused partial martensitic breakdown of the metastable β structure and for the one set of conditions investigated (test pieces quenched from 825° C, strained 10 percent in tension, and aged 24 hours at 550° C) reduced the strength and modulus obtained on aging. The density of the alloy was 4.92 gm/cc or 0.18 lb/cu in.

SOME EXPERIMENTS ON THE EXTRUSION OF MAGNESIUM AND ALUMINIUM POWDERS. H. G. Cole. February 1955. 23p. diagrs., photos., 5 tabs. (RAE Met. 85)

Smooth extrusions of good mechanical properties can be made from magnesium powders at low extrusion speeds provided the billet temperature exceeds 470° C. Conditions for the extrusion of some aluminum powders coarser than S. A. P. have been determined. The relation between pressure and density during the cold compacting of some magnesium and aluminum powders is recorded. Remnants of natural oxide films in extrusions often, but not always, stop the propagation of slip during straining. Some electron micrographs of aluminum oxide remnants are shown.

THE PERFORMANCE OF A MULTI-STAGE COMBUSTION SYSTEM. PART I - FLAME STABILITY OF RECIRCULATION ZONES. S. W. White and W. G. E. Lewis. May 1955. 16p. diagrs. (NGTE R.165)

As part of a general investigation into optimum rates of addition of combustible mixtures into a gaseous zone at high temperature, this report describes an experimental study into the factors influencing flame stability of cylindrical baffles admitting mixtures through a single row of holes in the periphery, the axis of the cylinder being parallel to the approaching airstream. The results show that for geometrically similar baffles the stability range can be correlated with $\frac{Q}{D^{2.4}p^{1.5}}$ where Q is the air flow rate, D is the baffle diameter and P is the combustion pressure.

Royal Aircraft Establishment (Gt. Brit.)
THE FLOW THROUGH SHORT STRAIGHT PIPES IN A COMPRESSIBLE VISCOUS STREAM. J. Seddon. April 1955. 34p. diagrs., photos. (RAE Aero 2542)

In the design of small models of aircraft or missiles for testing in supersonic tunnels, it may be desired to represent jet engine nacelles by means of simple hollow pipes. The note sets out the principal characteristics of compressible flow in such pipes at zero yaw and gives a theory for calculating the effect of the boundary layer. This is checked against the results of tests with a series of pipes of varying

size, at Mach numbers from 1.34 to 2.41. Curves are presented for determining the maximum length/radius ratio of a parallel pipe which will permit supersonic internal flow, in terms of the Mach number of the stream and Reynolds number of the pipe: the curves are given for both laminar and turbulent internal boundary layers. The effect of inclination of the pipe to the stream is discussed briefly, on the basis of results at one Mach number (1.86).

PRELIMINARY LOW SPEED WIND TUNNEL TESTS ON FLAT PLATES AND AIR BRAKES: FLOW, VIBRATION AND BALANCE MEASUREMENTS. R. Fail, T. B. Owen, and R. C. W. Eyre. January 1955. 45p. diagrs., 5 tabs. (RAE Tech. Note Aero 2356)

Flow measurements have been made behind sharp-edged flat plates: (a) at 90° for various shapes, and (b) for a square plate over an incidence range. The results of (a) show a closed bubble about 3 plate sides long, with a constant pressure boundary up to the maximum diameter, followed by mixing. Measurements of velocity fluctuations were made for (b), showing that a regular shedding of turbulent eddies occurs for $\theta = 50^{\circ}$ and over, but stops by 40°. Large random low frequency longitudinal fluctuations are associated with the shedding. Lift, drag, and pitching moment increments were measured on a square plate mounted on (a) a long cylinder, and (b) near the end of several shapes of rear fuselage, to see how the moments on opening the brake could be modified. Velocity fluctuation measurements, at 70° only, show a much reduced longitudinal unsteadiness when the plate is in proximity to the fuselage. Comparative tests were made on a cascade brake and show that no shedding occurs.

THE INFLUENCE OF METHYL BROMIDE ON FLAMES. I - PREMIXED FLAMES. II - DIFFUSION FLAMES. R. F. Simmons and H. G. Wolfhard. March 1955. 27p. diagrs., photos., 3 tabs. (RAE RPD 25)

The influence of methyl bromide and bromine on flames has been investigated. Both premixed and diffusion flames are chemically inhibited, in contrast to the purely diluting effect of inert gas. The most significant change in premixed flames on adding methyl bromide or bromine is that the limit temperature is raised. Limits of inflammability of mixtures cannot be calculated by Le Chatelier's rule. The action of methyl bromide in flames can be interpreted in terms of the addition of equivalent amounts of fuel and bromine. The structure of diffusion flames is completely changed when methyl bromide is introduced into the air, an additional reaction zone being formed on the air side in which the methyl bromide reacts with the air. Thus fuel and oxidant no longer meet in simple stoichiometric proportions in the main reaction zone. Methyl bromide has been found to be much more efficient as an extinguishant when introduced into the air than when added to the fuel.

A FIXTURE FOR TESTING SHEET MATERIALS IN COMPRESSION AT ELEVATED TEMPERATURES. D. C. Hayward. March 1955. 19p. diagrs., photos., 3 tabs. (RAE Tech. Note Met. 193)

A fixture for compressive testing of sheet material at elevated temperatures up to 400° C has been developed. The thinnest sheet tested was 20 S.W.G. (0.036 in.) Lateral support, to prevent buckling of the test specimens under high stress, was obtained from a series of steel balls spaced evenly on both sides of the specimen. An averaging extensometer, attached to opposite edges of the specimen, recorded changes in gage length and enabled readings of strain to include the 0.5 percent proof stress to be made. Compressive test readings compared favorably both for sensitivity and reproducibility with corresponding readings taken by established tensile test methods, the facility and simplicity of the compression test procedure equaling that of the tensile test.

Royal Aircraft Establishment (Gt. Brit.)
FURTHER WORK ON THE EFFECT OF HARD-ANODISING ON THE FATIGUE STRENGTH OF D.T.D. 364B ALUMINIUM ALLOY. E. G. Savage and E. G. F. Sampson. March 1955. 11p. diagrs., 5 tabs. (RAE Tech. Note Met. 216)

As suggested in a previous note, a modified form of treatment was used to produce hard anodic coatings on Wöhler-type fatigue test-pieces made from D.T.D. 364B aluminum alloy, with the object of reducing the ill effects due to treatment at a constant current density. This modified treatment failed to reduce the fatigue loss significantly. However, it was found that sealing the coatings in a boiling dichromate solution substantially improved the fatigue strength of parts which had been hard anodised by either the "standard" or the modified process, the losses of fatigue strength at 10 million cycles being reduced from 47 to 8 percent and 36 to 4 percent, respectively. The sealing treatment reduced the abrasion-resistance of the coatings by 20 percent. No further work is proposed.

A COMPARISON OF SOME DEVICES FOR REDUCING THE GROUND RUN DURING LANDING. D. Lean. May 1955. 29p. diagrs. (RAE Tech. Note Aero 2379)

With the thrust/weight ratios common today on jet aircraft, the size of brake parachute needed to equal the effect of the available reversed thrust is large but not excessive. For the future, increased touchdown speeds tend to favor the brake parachute, simply by increasing the mean drag. This gain is probably only partly cancelled by higher available reversed thrust. On the score of weight, cost, and complications, the parachute has the advantage, but from the handling point of view, pilots are likely to prefer the more controllable reversed thrust system. Too little is yet known of actual installations of thrust reversal schemes on typical aircraft for a comparison to be made on the grounds of reliability, or effect on the aircraft and its occupants.

Royal Aircraft Establishment (Gt. Brit.)
FLIGHT EXPERIMENTS ON BOUNDARY LAYER CONTROL FOR LOW DRAG. M. R. Head, D. Johnson, and M. Coxon. March 1955. 48p. diagrs., photos., 2 tabs. (RAE Aero 2541)

Tests have been made with distributed suction applied to a short span sleeve fitted to the upper surface of the wing of a single seat Vampire aircraft. Full chord laminar flow was maintained up to Reynolds numbers in the region of 29 million and Mach numbers up to 0.70, which was very nearly the critical Mach number of the sleeve section. The suction quantities required were sufficiently small to result in overall reductions in profile drag of between 70 and 80 percent, account being taken of the power required for suction. Difficulties were experienced due to surface roughness, and although these are believed to have resulted largely from the particular type of porous covering used in the tests, the problem of maintaining a sufficiently smooth and clean surface is evidently of crucial importance to full-scale application.

OPTICAL CHARACTERISTICS OF LAMINATED CAMERA WINDOWS. A. C. Marchant and B. M. Mathieson. March 1955. 24p. diagrs., photos., 2 tabs. (RAE Tech.Note Ph.489)

This note describes optical tests on laminated camera windows of both plane and spherical form. Photographic tests of their effect upon the resolving

power of an associated camera system have been carried out. The wedge angle of the windows has been measured, and the surface flatness and internal homogeneity of the plane windows tested; while the effects of the curved windows, upon the correction of the camera lens associated with them, has been assessed visually. It is concluded that the laminating process does not, in itself, introduce deleterious effects on optical performance. Plane windows, unless optically worked to a high degree of flatness, may introduce a focal shift which will, in practice, reduce resolving power. Curved windows, even when worked to have zero power, are shown to reduce overall resolution through the introduction of astigmatism and field curvature.

Royal Aircraft Establishment (Gt. Brit.) IMPURITIES IN TITANIUM: SULPHUR. D. A. Sutcliffe. March 1955. 13p. diagrs., photos., 7 tabs. (RAE Tech. Note Met. 218)

Binary titanium sulphur alloys containing up to 1.05 percent sulphur have been prepared by arc melting. Tensile, hardness, and impact tests have been made on the alloys at room temperature. The results show that the addition of approximately 0.1 percent sulphur causes a marked rise in tensile strength and hardness with a corresponding fall in elongation and impact strength. Further additions up to 1.05 percent sulphur cause only a small increase in tensile strength and hardness, but the elongation and impact strength continue to decrease steadily, though less rapidly than at first.

THE ICING PROBLEM: CURRENT STATUS OF NACA TECHNIQUES AND RESEARCH. Uwe H. von Glahn. (Preprint of paper presented at Ottawa AGARD Conference, June 10-17, 1955). 44p. diagrs., photos.

Icing tunnel facilities, operational techniques, and icing instruments are described in appendices to this paper.

DECLASSIFIED NACA REPORTS

We have

NACA RM A50L04

PRELIMINARY FLIGHT INVESTIGATION OF THE MANEUVERING ACCELERATIONS AND BUFFET BOUNDARY OF A 35° SWEPT-WING AIRPLANE AT HIGH ALTITUDE AND TRANSONIC SPEEDS. George A. Rathert, Jr., Howard L. Ziff, and George E. Cooper. February 21, 1951. 12p. diagrs., photo., tab. (NACA RM A50L04) (Declassified from Confidential, 7/20/55)

Results are presented from a series of exploratory flights on a swept-wing fighter airplane up to 1.09 Mach number to show the effects of compressibility presently limiting the maneuverability. The buffet boundary is also presented.

NACA RM A51B21

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF AN AIRPLANE CONFIGURATION WITH AN ASPECT RATIO 2 TRIANGULAR WING AND AN ALL-MOVABLE HORIZONTAL TAIL-LONGITUDINAL CHARACTERISTICS. David Graham and David G. Koenig. April 23, 1951. 35p. diagrs., photo., 3 tabs. (NACA RM A51B21) (Declassified from Confidential, 8/17/55)

Force tests were made with an all-movable horizontal tail in three vertical positions above the extended wing-chord plane (0, 0.25, and 0.50 wing semispan) at one longitudinal distance aft of the wing. Downwash variations at the position of the horizontal tail as obtained from force tests and from a downwash survey are compared. The results indicated that, from a standpoint of longitudinal stability at low speed, the best of the positions of the horizontal tail tested would be that in the extended wing-chord plane. The Reynolds number of the tests was 14.6×10^6 and the Mach number was 0.13.

NACA RM A51H10a

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF AN AIRPLANE CONFIGURATION WITH AN ASPECT RATIO 4 TRIANGULAR WING AND AN ALL-MOVABLE HORIZONTAL TAIL - LONGITUDINAL CHARACTERISTICS. David Graham and David G. Koenig. October 1951. 27p. diagrs., photo., 4 tabs. (NACA RM A51H10a) (Declassified from Confidential, 8/17/55)

Force tests were made of the wing alone, wing fuselage, wing-fuselage vertical-tail, and complete configuration with each of two horizontal tails. The tails were located at each of three vertical positions above the extended wing-chord plane (0, 0.18, and 0.36 wing semispan) at one longitudinal distance aft of the wing. Downwash variations as obtained from force tests are presented. The Reynolds number of the tests was 10.9×10^6 and the Mach number was 0.13. The results indicated that, from a standpoint of longitudinal stability at low speed, the best of the positions of the horizontal tail tested would be that in the extended wing-chord plane.

NACA RM A53E01

COMPARISON OF THE EXPERIMENTAL AND THEORETICAL DISTRIBUTIONS OF LIFT ON A SLENDER INCLINED BODY OF REVOLUTION AT M = 2. Edward W. Perkins and Donald M. Kuehn. August 1953. 39p. diagrs., photos., 2 tabs. (NACA RM A53E01) (Declassified from Confidential, 8/17/55)

An investigation of the pressure distribution for a body of revolution, consisting of a 33-1/3-caliber (5.75 fineness ratio) tangent ogival nose and a cylindrical afterbody, has been made for an angle-of-attack range of 0° to 35.5° at a Mach number of 1.98 and a Reynolds number of approximately 0.5×10^6, based on body diameter. Comparisons of the theoretical and experimental pressure distributions are made to show the nature of the effects of both viscosity and cross-flow compressibility. The experimental load distributions are compared with those predicted by the method suggested in NACA RM A9I26 which includes an approximate method for taking into account the effects of viscosity on the lift distribution.

NACA RM E50H07

PERFORMANCE OF 4600-POUND-THRUST CENTRIFUGAL-FLOW-TYPE TURBOJET ENGINE WITH WATER-ALCOHOL INJECTION AT INLET. Philip W. Glasser. October 9, 1950. 24p. diagrs. (NACA RM E50H07) (Declassified from Confidential, 8/17/55)

An experimental investigation of the effects of injecting a water-alcohol mixture of 2:1 at the compressor inlet of a centrifugal-flow-type turbojet engine was conducted in an altitude test chamber at static sea-level conditions and at an altitude of 20,000 feet with a flight Mach number of 0.78 with an engine operating at rated speed. The net thrust was augmented by 0.16 for both flight conditions with a ratio of injected liquid to air flow of 0.05. Further increases in the liquid-air ratio did not give comparable increases in thrust.

NACA RM E50H30

ALTITUDE INVESTIGATION OF PERFORMANCE OF TURBINE-PROPELLER ENGINE AND ITS COMPONENTS. Lewis E. Wallner and Martin J. Saari. October 5, 1950. 65p. diagrs., photos. (NACA RM E50H30) (Declassified from Confidential, 8/17/55)

An investigation was conducted on a turbine propeller engine in the NACA Lewis altitude wind tunnel at altitudes from 5,000 to 35,000 feet. The applicability of generalized parameters to turbine-propeller engine data, analyses of the compressor, the combustion chambers, and the turbine, and a study of the overall engine performance are reported. Engine performance data obtained at sea-level static conditions could be used to predict static performance at altitudes up to 35,000 feet by use of the standard generalized parameters.

NACA RM E52H07

PROCEDURE FOR CALCULATING TURBINE BLADE TEMPERATURES AND COMPARISON OF CALCULATED WITH OBSERVED VALUES FOR TWO STATIONARY AIR-COOLED BLADES. W. Byron Brown, Henry O. Slone, and Hadley T. Richards. September 1952. 38p. diagrs. (NACA RM E52H07) (Declassified from Confidential, 8/17/55)

Local and average blade temperatures were calculated for two stationary air-cooled turbine blades with 10 tubes and 13 fins forming the internal heat-transfer surfaces. These temperatures were calculated using previously published NACA temperature-distribution equations and the most recent theories for determining heat-transfer coefficients, including for the first time the allowance for effects of variable wall temperature on gas-to-blade heat-transfer coefficients at the leading and trailing sections of turbine blades. Comparison of calculated and experimental blade temperatures, for gas temperatures of 300° and 1000° F, resulted in good agreement.

NACA RM E53H05

CONSIDERATIONS IN THE ADAPTATION OF LOW-COST FUELS TO GAS-TURBINE-POWERED COMMERCIAL AIRCRAFT. Henry C. Barnett and Richard J. McCafferty. October 1953. 59p. diagrs., photo., 2 tabs. (NACA RM E53H05) (Declassified from Confidential, 8/17/55)

In recent months interest has increased in the possible use of distillate and residual fuel oils as fuels for commercial gas-turbine aircraft. However, the use of such fuels entails the solution of many problems pertaining to fuel physical properties and combustion characteristics. This report reviews some of these problems and discusses the status of current knowledge in relation to their solution. The fuel combustion characteristics considered in this study are ignition, combustion efficiency, combustion stability, and carbon deposition. In addition the effects of distillate and residual fuels on exhaust deposits and corrosion are discussed. Preliminary calculated data are presented to indicate preheating requirements for maintaining fuel fluidity and desirable fuel-injection properties.

NACA RM L7H26

FLIGHT INVESTIGATION TO DETERMINE THE HINGE MOMENTS OF A BEVELED-EDGE AILERON ON A 45° SWEPTBACK WING AT TRANSONIC AND LOW SUPERSONIC SPEEDS. William N. Gardner and Howard J. Curfman, Jr. November 12, 1947. 20p. diagrs., photos. (NACA RM L7H26) (Declassified from Confidential, 8/17/55)

An RM-1 stability and control research pilotless aircraft was used to measure aileron hinge moments in flight. The 20° beveled edge, $0.52c_a$ overhang balance aileron experienced a rapid increase and then decrease in hinge moments as the critical speed was exceeded (M = 0.86 to 0.92). At supercritical speeds (M = 0.92 to 1.23) the hinge moments increased rapidly. Rolling-moment balance data indicate aileron effectiveness reversal at supercritical speeds.

NACA RM L8E04

EFFECT OF WINDSHIELD SHAPE OF A PILOT'S CANOPY ON THE DRAG OF AN NACA RM-2 DRAG RESEARCH MODEL IN FLIGHT AT TRANSONIC SPEEDS. Sidney R. Alexander. July 21, 1948. 6p. diagrs. (NACA RM L8E04) (Declassified from Confidential, 8/17/55)

Results of flight tests of an NACA RM-2 drag research model equipped with a pilot's canopy having a vee windshield are presented for a Mach number range from 0.75 to 1.43. Comparison is made with test results of a similar canopy having a flat windshield. The vee-windshield canopy produced lower drag-coefficient values than the flat-windshield canopy for Mach numbers from 0.85 to about 1.2. From M = 1.2 to 1.4 both canopies produced the same drag coefficient.

NACA RM L8E10

FREE-FLIGHT INVESTIGATION OF THE ROLLING EFFECTIVENESS AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS OF LEADING-EDGE AND TRAILING-EDGE AILERONS IN CONJUNCTION WITH TAPERED AND UNTAPERED PLAN FORMS. H. Kurt Strass. July 23, 1948. 19p. diagrs., photos. (NACA RM L8E10) (Declassified from Confidential, 8/17/55)

Additional results of an aerodynamic-control-effectiveness investigation using free-flight, rocket-propelled test vehicles have been obtained recently which show some effects of leading-edge and trailing-edge ailerons tested both individually and in combination on wings with tapered and untapered plan forms.

NACA RM L8E12

LONGITUDINAL STABILITY CHARACTERISTICS OF A 42° SWEPTBACK WING AND TAIL COMBINATION AT A REYNOLDS NUMBER OF 6.8×10^6. Stanley H. Spooner and Albert P. Martina. July 22, 1948. 44p. diagrs., photos., 2 tabs. (NACA RM L8E12) (Declassified from Confidential, 8/17/55)

Presents results of wind-tunnel investigation at a Reynolds number of 6.8×10^6 to determine the static longitudinal stability characteristics of a 42° sweptback wing and fuselage combination with a sweptback horizontal tail. Includes effects of vertical position of fuselage and tail with respect to wing for several combinations of high-lift and stall-control devices. Also includes effect of a simulated ground.

NACA RM L8G20a

FREE-FLIGHT INVESTIGATION AT TRANSONIC AND SUPERSONIC SPEEDS OF THE ROLLING EFFECTIVENESS OF A THIN, UNSWEPT WING HAVING PARTIAL-SPAN AILERONS. Carl A. Sandahl. October 22, 1948. 13p. diagrs., photos., tab. (NACA RM L8G20a) (Declassified from Confidential, 7/20/55)

Tests of the rolling effectiveness at transonic and supersonic speeds of a thin, unswept wing having partial-span ailerons have been made by means of rocket-propelled test vehicles. The results showed that with 4.6° aileron deflection, the only deflection tested, the rolling effectiveness decreased abruptly in the Mach number range from about 0.92 to 0.97. At supersonic speeds the rolling effectiveness was considerably lower than at subsonic speeds. The direction of roll was, in the correct sense, over the entire Mach number range investigated.

NACA RM L9H19

A STUDY OF SEVERAL FACTORS AFFECTING THE STABILITY CONTRIBUTED BY A HORIZONTAL TAIL AT VARIOUS VERTICAL POSITIONS ON A SWEPTBACK-WING AIRPLANE MODEL. Gerald V. Foster and Roland F. Griner. October 28, 1949. 28p. diagrs., tab. (NACA RM L9H19) (Declassified from Confidential, 8/17/55)

Results are presented of a study made in the Langley 19-foot pressure tunnel at a Reynolds number of 6.8×10^6 to determine the effects of fuselage afterbody shape, split flaps, and a reduction in the span of 0.575-span leading-edge flaps on the stability contributed by a horizontal tail at various heights to a 42° sweptback wing-fuselage combination. Results are also presented of air-flow surveys in the vicinity of the tail with the wing flaps deflected.

NACA RM L50G14b

EXPERIMENTAL DETERMINATION OF EFFECT OF STRUCTURAL RIGIDITY ON ROLLING EFFECTIVENESS OF SOME STRAIGHT AND SWEPT WINGS AT MACH NUMBERS FROM 0.7 TO 1.7. H. Kurt Strass, E. M. Fields, and Paul E. Purser. October 4, 1950. 40p. diagrs., photo., tab. (NACA RM L50G14b) (Declassified from Confidential, 7/20/55)

The effect of varying the wing structural rigidity on the control effectiveness of a 0.2-chord, plain, faired, full-span aileron on untapered wing plan forms having 0° and 45° sweep and aspect ratio of 3.7 has been investigated with rocket-propelled test vehicles. The test results are compared with results obtained from existing theory. Aerodynamic twisting moments are evaluated from the experimental rolling-loss data.

NACA RM L50H28

TABULATED PRESSURE COEFFICIENTS AND AERODYNAMIC CHARACTERISTICS MEASURED ON THE WING OF THE BELL X-1 AIRPLANE IN PULL-UPS AT MACH NUMBERS FROM 0.53 TO 0.99. Ronald J. Knapp and Gertrude V. Wilken. November 1, 1950. 77p. diagrs., photo., 11 tabs. (NACA RM L50H28) (Declassified from Confidential, 8/17/55)

Presents tabulated pressure coefficients and aerodynamic characteristics measured on the left wing of the Bell X-1 airplane in 10 pull-ups from Mach numbers of approximately 0.53 to 0.99.

NACA RM L50J16

DYNAMIC STABILITY AND CONTROL CHARACTERISTICS OF A VERTICALLY RISING AIRPLANE MODEL IN HOVERING FLIGHT. William R. Bates, Powell M. Lovell, Jr., and Charles C. Smith, Jr. February 23, 1951. 16p. diagrs., photos., tab. (NACA RM L50J16) (Declassified from Confidential, 8/17/55)

An investigation is being made to determine the stability and control characteristics of a vertically rising airplane model. This paper presents the results of some preliminary hovering flight tests made in still air with two center-of-gravity positions, 0-percent and 45-percent mean aerodynamic chord and with normal airplane-type controls operating in the slipstream.

NACA RM L51G05

EFFECT OF THE PROXIMITY OF THE GROUND ON THE STABILITY AND CONTROL CHARACTERISTICS OF A VERTICALLY RISING AIRPLANE MODEL IN THE HOVERING CONDITION. Charles C. Smith, Jr., Powell M. Lovell, Jr., and William R. Bates. September 1951. 16p. diagrs., tab. (NACA RM L51G05) (Declassified from Confidential, 8/17/55)

An investigation has been made to determine the effect of the proximity of the ground on the stability and control characteristics of a vertically rising airplane model in the hovering condition. The model was essentially a conventional airplane model having a dual-rotating propeller in a tractor arrangement, a rectangular wing and a cruciform tail with rectangular surfaces. The investigation included take-offs and landings and hovering flight tests near the ground, force tests with and without a ground board, and dynamic-pressure surveys at various radial and longitudinal stations behind the propeller.

NACA RM L51H13a

DYNAMIC STABILITY AND CONTROL CHARACTERISTICS OF A DELTA-WING VERTICALLY RISING AIRPLANE MODEL IN TAKE-OFFS, LANDINGS, AND HOVERING FLIGHT. Powell M. Lovell, Jr., William R. Bates and Charles C. Smith, Jr. October 1951. 14p. diagrs., photo., tab. (NACA RM L51H13a) (Declassified from Confidential, 8/17/55)

An investigation has been conducted by means of tests of a flying model in still air to determine the dynamic stability and control characteristics of a delta-wing vertically rising airplane in the take-off, landing, and hovering phases of flight. The model had a dual-rotating propeller in a tractor arrangement, a modified triangular wing, and modified triangular vertical-tail surfaces mounted symmetrically above and below the fuselage, but had no horizontal tail. Control was provided by elevons and rudders operating in the propeller slipstream.

NACA RM L51H14

DAMPING IN ROLL OF STRAIGHT AND 45° SWEPT WINGS OF VARIOUS TAPER RATIOS DETERMINED AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS WITH ROCKET-POWERED MODELS. E. Claude Sanders, Jr. October 1951. 15p. diagrs. (NACA RM L51H14) (Declassified from Confidential, 8/17/55)

Rocket-powered flight tests have been conducted to determine the damping in roll of several wings of 0° and 45° quarter-chord line sweep with various taper ratios. The Mach number range of these tests was from 0.8 to 1.45. Damping in roll decreased with decreasing taper ratio at approximately the same rate for swept and unswept wings, and was also decreased by sweeping the quarter-chord line. Experimental data were much lower than that predicted by theory for the swept wings. The drag at zero lift was consistently of a lower magnitude for the 45° swept tapered series than for the unswept tapered series.

NACA RM L51H16

INVESTIGATION OF THE EFFECT OF A NACELLE AT VARIOUS CHORDWISE AND VERTICAL POSITIONS ON THE AERODYNAMIC CHARACTERISTICS AT HIGH SUBSONIC SPEEDS OF A 45° SWEPTBACK WING WITH AND WITHOUT A FUSELAGE. H. Norman Silvers, Thomas J. King, Jr., and Thomas B. Pasteur, Jr. September 1951. 71p. diagrs., photos., 3 tabs. (NACA RM L51H16) (Declassified from Confidential, 8/17/55)

An investigation of a nacelle was made over a Mach number range from 0.40 to 0.90 to determine the interference characteristics between the nacelle and a semispan model having a wing with the quarter-chord line swept back 45° and a fuselage of fineness ratio 10. The nacelle was a body of revolution of fineness ratio 5.0 with a profile that was a modified NACA 65-series airfoil section. The nacelle was investigated in several chordwise positions and vertical locations.

NACA RM L51I07a

ADDITIONAL STUDIES OF THE STABILITY AND CONTROLLABILITY OF AN UNSWEPT-WING VERTICALLY RISING AIRPLANE MODEL IN HOVERING FLIGHT INCLUDING STUDIES OF VARIOUS TETHERED LANDING TECHNIQUES. William R. Bates, Powell M. Lovell, Jr., and Charles C. Smith, Jr. Movember 1951. 25p. diagrs., photos., tab. (NACA RM L51I07a) (Declassified from Confidential, 8/17/55)

This paper is the third of a series presenting the results of an investigation of the stability and control characteristics of a flying model of an unswept-wing vertically rising airplane. The investigation consisted of flight tests to determine the effects of some miscellaneous factors on the stability and control characteristics for the hovering condition and to study the behavior of the model for various landing techniques involving the use of lines for pulling the model in for a landing.

NACA RM L52H12

LOW-LIFT BUFFET CHARACTERISTICS OBTAINED FROM FLIGHT TESTS OF UNSWEPT THIN INTERSECTING SURFACES AND OF THICK 35° SWEPTBACK SURFACES. Homer P. Mason. January 1953. 21p. diagrs., photos. (NACA RM L52H12) (Declassified from Confidential, 8/17/55)

Results of flight tests of two rocket-propelled rearch models are presented. The effect of the intersection of thin surfaces and the effect of moderate sweepback of a thick surface on the low-lift buffeting and trim characteristics of a clean body-tail configuration are shown. Drag coefficients are presented and compared with previous data to show the effect of tail position and sweep.

NACA RM L53G15

INVESTIGATION OF A RELATED SERIES OF TURBINE-BLADE PROFILES IN CASCADE. James C. Dunavant and John R. Erwin. December 1953. 100p. diagrs. (NACA RM L53G15) (Declassified from Confidential, 8/17/55)

Series of directly related turbine blade shapes uniformly variable in camber are designed to satisfy the usual turbine-blade operating requirements of inlet air angle and turning angle. Low-speed cascade test results of five blade sections and sample high-speed cascade tests for two blade sections of these series are presented. A method of properly cambering turbine blade shapes based on low-speed test results is given.

NACA RM L53H21

INVESTIGATION OF REYNOLDS NUMBER EFFECTS FOR A SERIES OF CONE-CYLINDER BODIES AT MACH NUMBERS OF 1.62, 1.93, AND 2.41. Carl E. Grigsby and Edmund L. Ogburn. October 1953. 20p. diagrs., photos. (NACA RM L53H21) (Declassified from Confidential, 8/17/55)

An investigation of the Reynolds number for transition and the skin-friction drag at zero lift of eight cone-cylinder bodies having varying fineness ratios has been made at Mach numbers of 1.62, 1.93, and 2.41 over a Reynolds number range from 0.3×10^6 to 10×10^6. The accuracy of the skin-friction data was not sufficient to permit any general conclusions to be drawn. The Reynolds number for transition was found to be dependent upon both the tunnel stagnation pressure and Mach number.

NACA RM L53K12

A SUMMARY OF INFORMATION ON SUPPORT INTERFERENCE AT TRANSONIC AND SUPERSONIC SPEEDS. Eugene S. Love. January 1954. 26p. diagrs. (NACA RM L53K12) (Declassified from Confidential, 8/17/55)

A compilation of available information on the problem of support interference at transonic and supersonic speeds is presented.

NACA RM L53L23a

WIND-TUNNEL INVESTIGATION OF A SHIELDED TOTAL-PRESSURE TUBE AT A MACH NUMBER OF 1.61. Walter R. Russell and William Gracey. March 1954. 9p. diagrs., photo. (NACA RM L53L23a) (Declassified from Confidential, 8/17/55)

Wind-tunnel tests of the variation of total-pressure error with angle of attack of a shielded total-pressure tube over an angle-of-attack range of 0° to 60° and at a Mach number of 1.61 are presented. The tests showed that the total-pressure error was zero up to an angle of attack of 34°, increased to $0.035q_c'$ (where q_c' is the indicated impact pressure) at 48°, then began to decrease and reached a value of zero at 55° and $-0.07q_c'$ at 59.5°.

NACA RM L54C18

DYNAMIC STABILITY AND CONTROL CHARACTERISTICS OF A DUCTED-FAN MODEL IN HOVERING FLIGHT. Robert H. Kirby. April 1954. 16p. diagrs., photos. (NACA RM L54C18) (Declassified from Confidential, 8/17/55)

This paper presents the results of an experimental investigation of the dynamic stability and control of a simple ducted-fan model in hovering flight and is intended to provide some basic information on the stability and control of jet vertically rising airplanes in hovering flight. The model consisted of an 18-inch-diameter dual-rotating propeller in a shroud 4 feet long. Control was provided by all-movable surfaces at the rear of the shroud. The investigation consisted mainly of flight tests with the model hovering at altitude and near the ground.

National Advisory Committee for Aeronautics

Research Abstracts

NO. 90 SEPTEMBER 27, 1955

CURRENT NACA REPORTS

NACA Rept. 1197

A STUDY OF THE CHARACTERISTICS OF HUMAN-PILOT CONTROL RESPONSE TO SIMULATED AIRCRAFT LATERAL MOTIONS. Donald C. Cheatham. 1954. ii, 14p. diagrs., photos., tab. (NACA Rept. 1197. Formerly RM L52C17)

There are presented studies of the characteristics of pilot ability to control dynamically unstable yawing oscillations, studies of pilot control response to simulated aircraft yawing motions, and studies of the feasibility of representing pilot control response in an analytical form.

NACA RM E55F28a

STATISTICAL SURVEY OF ICING DATA MEASURED ON SCHEDULED AIRLINE FLIGHTS OVER THE UNITED STATES AND CANADA FROM NOVEMBER 1951 TO JUNE 1952. Porter J. Perkins. September 1955. 44p. diagrs., photos., 2 tabs. (NACA RM E55F28a)

A statistical survey and a preliminary analysis are made in an interim report of over 600 icing encounters obtained from a continuing program sponsored by the NACA with the cooperation of the airlines. Pressure-type icing-rate meters were installed on 11 airline aircraft of various types. Icing conditions measured during scheduled operations gave relative frequencies of liquid-water content, icing rate, total ice accumulations, cloud temperatures, as well as horizontal and vertical extent of icing clouds. Liquid-water contents were higher than data from earlier research flights in layer-type clouds but slightly lower than previous data from cumulus clouds.

NACA TM 1330

THEORY OF DYNAMIC CREEP. (K teorii dinamicheskoi polzuchesti). A. A. Predvoditelev and B. A. Smirnov. September 1955. 12p. diagr. (NACA TM 1330. Trans. from Moscow Universitet, Vestnik, v.8, no.8, 1953, p.79-86)

An analysis is given of the causes of the increase in creep under varying loads. It is suggested that the increase in creep is due to local rise in temperature over the slip planes, thus facilitating slip. A theory of dynamic creep is proposed, based on the Becker theory of the after-effect, which treats the metal as a granular structure and includes a rate factor. Comparison of the theory with experimental results is reserved for a future paper.

NACA TN 3293

CUMULATIVE FATIGUE DAMAGE OF AXIALLY LOADED ALCLAD 75S-T6 AND ALCLAD 24S-T3 ALUMINUM-ALLOY SHEET. Ira Smith, Darnley M. Howard, and Frank C. Smith, National Bureau of Standards. September 1955. 49p. diagrs., photos., 5 tabs. (NACA TN 3293)

Results are presented of cumulative-fatigue-damage tests made on 607 specimens machined from alclad 75S-T6 aluminum-alloy sheet 0.064 inch thick and 198 specimens of alclad 24S-T3 and alclad 75S-T6 aluminum-alloy sheet 0.032 inch thick. The tests of the 0.064-inch-thick specimens consisted of 35 different loading conditions and the tests of the 0.032-inch material consisted of 13 different loading conditions.

NACA TN 3294

FRICTION STUDY OF AIRCRAFT TIRE MATERIAL ON CONCRETE. W. G. Hample, Boeing Airplane Company. September 1955. 34p. diagrs., photos. (NACA TN 3294)

A systematic study was made of the variation of frictional resistance between typical tire-tread material and three concrete surfaces of different roughness at various temperatures and normal pressures. The tire-tread specimens were taken from the thickest portion of worn ten-ply tires, and the three concrete test blocks were poured from the same mix but subjected to different surface finishes. Curves are presented of the apparent coefficient of friction as a function of normal pressure.

NACA TN 3477

HYDRODYNAMIC PRESSURE DISTRIBUTIONS OBTAINED DURING A PLANING INVESTIGATION OF FIVE RELATED PRISMATIC SURFACES. Walter J. Kapryan and George M. Boyd, Jr. September 1955. 82p. diagrs., photos., 5 tabs. (NACA TN 3477)

Hydrodynamic pressure distributions have been obtained during pure planing for five related prismatic surfaces. The distributions gave integrated lifts that in almost every case were well within 10 percent of the applied load. Comparison of experiment with theory shows that existing theories will adequately predict flat-plate pressures. For the V-shaped surfaces, experiment and theory are in poor agreement. The lift and center-of-pressure data for both the flat and V-shaped surfaces are in good agreement with recent experimental and theoretical NACA research on planing surfaces.

NACA TN 3479

ANALYSIS OF THE HORIZONTAL-TAIL LOADS MEASURED IN FLIGHT ON A MULTIENGINE JET BOMBER. William S. Aiken, Jr. and Bernard Wiener. September 1955. i, 69p. diagrs., photo., 6 tabs. (NACA TN 3479)

Horizontal-tail loads were measured in gradual and abrupt longitudinal maneuvers on two configurations of a four-engine jet bomber. The results obtained have been analyzed to determine the flight values of the coefficients important in calculations of horizontal tail loads. The least-squares procedure used to determine aerodynamic tail loads from strain-gage measurements of structural tail loads which were affected by temperature is covered in detail. The effect of fuselage flexibility on the airplane motion is considered in the analysis of the abrupt-maneuver data. When possible, wind-tunnel results are compared with flight results. Some calculations of critical horizontal-tail loads beyond the range of the tests are given and compared with design loads.

NACA TN 3486

MEASUREMENTS OF TURBULENT SKIN FRICTION ON A FLAT PLATE AT TRANSONIC SPEEDS. Raimo J(aakko) Hakkinen, California Institute of Technology. September 1955. 41p. diagrs., photo., tabs. (NACA TN 3486)

The design and construction of a floating-element skin-friction balance are described. This instrument was applied to measurements of local skin friction in the turbulent boundary layer of a smooth flat plate at high-subsonic Mach numbers and supersonic Mach numbers up to 1.75. The principal difficulties which exist in comparing skin-friction coefficients at various Mach numbers are discussed.

NACA TN 3491

EXPERIMENTAL INVESTIGATION OF ECCENTRICITY RATIO, FRICTION, AND OIL FLOW OF LONG AND SHORT JOURNAL BEARINGS WITH LOAD-NUMBER CHARTS. G(eorge) B. DuBois, F(red) W. Ocvirk, and R. L. Wehe, Cornell University. September 1955. 63p. diagrs., tabs. (NACA TN 3491)

The performance of plain bearings under steady central loading are compared and summarized by single-line curves covering the range of length-diameter ratios both above and below 1. Experimental date on eccentricity ratio, friction, and oil flow for length-diameter ratios of 1, 1-1/2, and 2 are shown for comparison with earlier data for length-diameter ratios of 1/4, 1/2, and 1. The combined data provide charts of plain-bearing performance which cover the practical range of length-diameter ratio.

NACA TN 3493

DEVELOPMENT OF EQUIPMENT AND OF EXPERIMENTAL TECHNIQUES FOR COLUMN CREEP TESTS. Sharad A. Patel, Martin Bloom, Burton Erickson, Alexander Chwick and N(icholas) J(ohn) Hoff, Polytechnic Institute of Brooklyn. September 1955. 20p. diagrs., photos., tab. (NACA TN 3493)

Equipment and procedures developed for testing aluminum-alloy columns subjected to constant loads at elevated temperatures are described. Particular emphasis was put on determination of the influence of initial deviations from straightness on the critical time of the column, that is, the time necessary for the column to buckle when subjected to a constant load. Results are presented of tests of a number of 2024-T4 aluminum-alloy columns having large slenderness ratios.

NACA TN 3503

REDUCTION OF PROFILE DRAG AT SUPERSONIC VELOCITIES BY THE USE OF AIRFOIL SECTIONS HAVING A BLUNT TRAILING EDGE. Dean R. Chapman. September 1955. 29p. diagrs., photo. (NACA TN 3503. Supersedes RM A9H11)

A preliminary theoretical and experimental investigation has been made on the aerodynamic characteristics of blunt-trailing-edge airfoils at supersonic velocities. The theoretical considerations indicate that properly designed airfoils with moderately blunt trailing edges can have less profile drag, greater lift-curve slope, and a higher maximum lift-drag ratio than conventional sections. These predictions have been substantiated by experimental measurements on airfoils of 10-percent-thickness ratio at Mach numbers of 1.5 and 2.0, and at Reynolds numbers between 0.2 and 1.2 million.

NACA TN 3514

RESPONSE OF HOMOGENEOUS AND TWO-MATERIAL LAMINATED CYLINDERS TO SINUSOIDAL ENVIRONMENTAL TEMPERATURE CHANGE, WITH APPLICATIONS TO HOT-WIRE ANEMOMETRY AND THERMOCOUPLE PYROMETRY. Herman H. Lowell and Norman (A.) Patton. September 1955. ii, 143p. diagrs., tabs. (NACA TN 3514)

A theoretical investigation of the response of homogeneous and two-material laminated, infinite cylinders to sinusoidal environmental temperature and/or small heat-transfer coefficient changes was made. Generalized results are given for the cylinder consisting of a shell of high thermal conductivity and a core of low conductivity. The behavior of a number of specific platinum-fused-quartz "wires" of varying construction and diameter exposed to a representative airstream is indicated. For ratios of metal thickness to over-all radius of 0.1, response amplitude gains of about 4.5 are predicted as compared with gains of more than 10 for infinitesimal shells. For a relative shell thickness of 0.05, frequency responses of hot-wire anemometers, exposed-wire resistance thermometers, or thermocouples would be extended by at least an order of magnitude. Simplified analyses are included which are not exact but are adequate for design use.

NACA TN 3522

MEASUREMENTS OF THE EFFECTS OF FINITE SPAN ON THE PRESSURE DISTRIBUTION OVER DOUBLE-WEDGE WINGS AT MACH NUMBERS NEAR SHOCK ATTACHMENT. Walter G. Vincenti. September 1955. 50p. diagrs. (NACA TN 3522)

Results are presented of measurements at low supersonic speeds of the pressure distribution on two wings having a common double-wedge section and aspect ratios 2 and 4. Comparable results for aspect ratio infinity have been published in NACA TN 3225. The results cover the Mach number range from 1.166 to 1.377, which brackets the value (1.221) for bow-wave attachment at zero angle of attack. The data are discussed and compared with the previous two-dimensional findings.

NACA TN 3523

THE EFFECTIVENESS OF WING VORTEX GENERATORS IN IMPROVING THE MANEUVERING CHARACTERISTICS OF A SWEPT-WING AIRPLANE AT TRANSONIC SPEEDS. Norman M. McFadden, George A. Rathert, Jr., and Richard S. Bray. September 1955. 43p. diagrs., photos., tab. (NACA TN 3523. Supersedes RM A51J18)

The effects of wing vortex generators, multiple boundary-layer fences, and extension of the outer two segments of the wing leading-edge slats on the aerodynamic characteristics of a 35° swept-wing fighter were measured in flight tests at transonic speeds and high altitudes. Significant improvements were obtained in the pitch-up and wing-dropping-tendency characteristics with certain arrnagements of vortex generators.

NACA TN 3562

VARIATION OF BOUNDARY-LAYER TRANSITION WITH HEAT TRANSFER ON TWO BODIES OF REVOLUTION AT A MACH NUMBER OF 3.12. John R. Jack and N. S. Diaconis. September 1955. 16p. diagrs., photos. (NACA TN 3562)

Cooling a cone-cylinder model to a wall-to-free-stream ratio of approximately 1.4 increased the transition Reynolds number from a value of 2.0×10^6 at equilibrium to 10.6×10^6. For temperature ratios less than 1.4, the boundary-layer flow was entirely laminar. For a parabolic-nosed body, the transition Reynolds number was about twice that of the cone-cylinder model over the temperature range investigated.

NACA TN 3563

HEAT LOSS FROM YAWED HOT WIRES AT SUBSONIC MACH NUMBERS. Virgil A. Sandborn and James C. Laurence. September 1955. 44p. diagrs., photo. (NACA TN 3563)

Heat-loss data at angles of yaw and fixed subsonic Mach numbers for several wires of different diameters commonly used in hot-wire anemometry are presented. Possible methods of correlating the data are examined. The relation of the Reynolds number normal to the flow, which has been used by most researchers, was inadequate except near a Mach number of zero. An empirical relation based on weighted addition of the heat losses of wires normal and parallel to the flow correlated all data reasonably well.

NACA TN 3566

A POLAR-COORDINATE SURVEY METHOD FOR DETERMINING JET-ENGINE COMBUSTION-CHAMBER PERFORMANCE. Robert Friedman and Edward R. Carlson. September 1955. 29p. diagrs., photo., tab. (NACA TN 3566)

An automatic polar-coordinate traversing system is described that sweeps a probe through a quarter-annular exhaust duct circumferentially at selected radial positions. With a single combined pressure and temperature probe, temperature and pressure are recorded simultaneously as a function of probe position. The use of these data in calculating temperature and flow profiles, combustion efficiency, and pressure loss is shown.

THE USE OF QUARTZ IN THE MANUFACTURE OF SMALL DIAMETER PITOT TUBES. J. R. Cooke. 1955. 14p. diagrs., photos., tab. (ARC CP 193)

This note describes the method of manufacture of small quartz-tipped pitot tubes (down to 0.005 in. outside tip diameter) which have been used successfully for boundary-layer measurements on small models in a supersonic wind tunnel. Tests have been made of the effects of taper and end finish on the accuracy of measurement, and of the effect of the inside diameter of the tip (for a standard taper) on response rate. For a given inside tip diameter the tapered quartz tubes gave a faster response rate than the stainless steel hypodermic tubes previously used.

A NOTE ON THE SOUND FROM WEAK DISTURBANCES OF A NORMAL SHOCK WAVE. Alan Powell. 1955. 10p. diagrs. (ARC CP 194)

The disturbances of a shock wave by sound waves or temperature fluctuations are studied in one dimension to a first-order approximation. In general, both sound waves and temperature fluctuations arise behind the shock wave. Expressions are given for their amplitudes and calculated for $\gamma = 1.4$. Sound waves colliding with the shock wave are amplified, but sound waves are almost annihilated by weak shock waves if originally travelling in the same direction as the shock wave. Small temperature fluctuations give rise to much sound on an acoustical scale.

REQUIREMENTS FOR UNIFORMITY OF FLOW IN SUPERSONIC WIND TUNNELS. D. E. Morris and K. G. Winter. 1955. 9p. diagr. (ARC CP 197)

An analysis is made of the effects of nonuniformity of flow on the pressure measurements on the surface of a model and also on the force and moment measurements. The following standards of flow uniformity are derived - variations in flow direction to be less than $\pm 0.1^{\circ}$ in the range $M = 1.4$ to 3; variation in Mach number to be less than ± 0.003 at $M = 1.4$ increasing to ± 0.01 at $M = 3$. A brief analysis is made of the errors in model manufacture and their effects on force and pressure measurements. Using the same standards as were used in deducing the requirements for flow uniformity quoted above, it is concluded that present standards of model manufacture are satisfactory overall, though for accurate pressure plotting tests at low supersonic Mach numbers a higher standard is desirable.

A CRITERION FOR THE PREDICTION OF THE RECOVERY CHARACTERISTICS OF SPINNING AIRCRAFT. T. H. Kerr. 1955. 22p. diagrs., tabs. (ARC CP 195)

It has been deduced that the two most important parameters are the unbalanced rolling-moment coefficient about the wind axis in the spin and the ratio of pitching to rolling moment of inertia. Using the results of full-scale spinning tests on 33 aircraft, it has been possible to establish empirical relationships between the estimated unbalanced rolling-moment coefficient and the inertia ratio which effectively divide the aircraft into the three groups which have satisfactory, borderline, and unsatisfactory recovery characteristics. A simple method is presented for estimating the unbalanced rolling-moment coefficient knowing only the shape of the aircraft. The empirical relationships should give a good indication of the spin-recovery characteristics on new designs.

MODEL TESTS ON THE EFFECTS OF SLIPSTREAM ON THE FLOW AT VARIOUS TAILPLANE POSITIONS ON A FOUR-ENGINED AIRCRAFT. PART I. TESTS WITH CONTRA-ROTATING PROPELLERS. D. E. Hartley, A. Spence, and D. A. Kirby. PART II. TESTS WITH SINGLE ROTATING PROPELLERS. D. A. Kirby. 1955. 37p. diagrs., tabs. (ARC R & M 2747; ARC 12,355; ARC 14,166. Supersedes RAE Aero 2322; RAE Aero 2322a)

Systematic wind-tunnel tests have been made to investigate the effects of slipstream on the flow near the tail plane of a typical civil transport with four contra-rotating propellers. Tail-plane height has been varied for each of several wing-body arrangements; only one tail plane and one propeller position have been used. This report presents the main results in the form of changes in mean downwash angle and velocity at the tail plane, as functions of tail-plane position, lift coefficient, and propeller thrust.

THE THEORETICAL WAVE DRAG OF SOME BODIES OF REVOLUTION. L. E. Fraenkel. 1955. 26p. diagrs., tab. (ARC R & M 2842; ARC 14,334. Supersedes RAE Aero 2420)

This report investigates the wave drag of bodies of revolution with pointed or open-nose forebodies and pointed or truncated afterbodies. The "quasi-cylinder" and "slender-body" theories are reviewed, a reversibility theorem is established, and the concept of the interference effect of a forebody on an afterbody is introduced. The theories are applied to bodies whose profiles are either straight or parabolic arcs, formulas and curves being given for forebody and afterbody drag, and for the interference drag. The results of the two theories are compared and are seen to agree well in the region of geometries where both theories are applicable.

AN EXPERIMENTAL INVESTIGATION OF STRESS DIFFUSION IN NON-BUCKLING PLATES. L. H. Mitchell. 1955. 20p. diagrs., photos. (ARC R & M 2878. Supersedes ARC 14,934; Strut 1540)

This report provides experimental results for comparison with theoretical analyses of stress diffusion problems. The structures considered consist of plane reinforced sheet which has been assumed not to buckle. Symmetrical loads are applied to the edge booms connected to the sheet by continuous no-slip joints. Attention is concentrated on the stress distribution near the ends of the parallel strips of plate. An outline of the existing theoretical work which is applicable to this type of problem is given. The stringer-sheet theory is compared with the photoelastic results. Some attention is also given to transverse end stiffeners which seem to have little effect on the shear stresses.

THE BOUNDARY LAYER WITH DISTRIBUTED SUCTION. M. R. Head. 1955. 100p. diagrs., photos., tabs. (ARC R & M 2783. Supersedes ARC 13,897; FM 1547; Perf. 771)

Experiments performed in flight at Reynolds numbers in the region of 3×10^6 have clearly demonstrated the stabilizing effect of small amounts of distributed suction on the laminar boundary layer. In the absence of a pressure gradient and in adverse gradients similar to those occurring on a normal airfoil, transition of the boundary layer to the turbulent form has been prevented by the use of such suction quantities as may be expected to lead to very considerable reductions in effective drag. It appears, however, that for extensive laminar flow to be achieved in this way, the surface must be free from such excrescences as would cause transition in the absence of suction.

METHODS FOR CALCULATING THE LIFT DISTRIBUTION OF WINGS (SUBSONIC LIFTING-SURFACE THEORY). H. Multhopp. 1955. 96p. diagrs., tabs. (ARC R & M 2884; ARC 13,439. Supersedes RAE Aero 2353)

These methods for calculating the load distribution on wings of any plan form are based on the conceptions of lifting-surface theory. Computer work time is shortened by careful choice of the positions of pivotal points, by plotting once for all those parts of the downwash integral which occur frequently and by a consequent application of approximate integration methods similar to those devised by the author for lifting-line problems. The basis of the method is to calculate the local lift and pitching moment at a number of chordwise sections from a set of linear equations satisfying the downwash conditions at two pivotal points in each section.

SIMPLE EVALUATION OF THE THEORETICAL LIFT SLOPE AND AERODYNAMIC CENTRE OF SYMMETRICAL AEROFOILS. H. C. Garner. 1955. 20p. tabs. (ARC R & M 2847. Supersedes ARC 14,337; Perf. 847; S & C 2561)

This paper presents a simple method of calculating theoretical values of the lift slope $(a_1)_T$ and the position of aerodynamic center h_T in two-dimensional incompressible flow. Starting with the ordinates of an airfoil, the method in section 3 provides first and second approximations to both derivatives, which are compared with exact theory and other calculated values in Tables 2 and 3 for various symmetrical airfoils listed in Table 1. In section 5 a correction to the first approximation is introduced so as to permit the evaluation of $(a_1)_T$ within 1/2 percent and h_T within about 0.001 in less than a quarter of an hour. A complete illustrative calculation is set out in Table 4.

BOUNDARY-LAYER CONTROL FOR HIGH LIFT BY SUCTION AT THE LEADING-EDGE OF A 40 DEG SWEPT-BACK WING. E. D. Poppleton. 1955. 38p. diagrs., tabs. (ARC R & M 2897; ARC 14,771. Supersedes RAE Aero 2440)

Wind-tunnel tests on the 10-percent-thick, constant-chord, aspect-ratio-4.6 wing are discussed. Boundary-layer control was applied along the whole leading edge; a comparison was made between the effects of distributed suction and suction through a

slot. A 45-percent Fowler flap was used in some tests. The overall effect of the two systems was similar, giving an increase in $C_{L_{max}}$ by increasing the stalling angle of attack and making the wing statically stable up to the stall, when there was a severe loss of lift. The tests were designed to determine whether leading-edge suction would produce comparable increases in $C_{L_{max}}$ on swept wings and, also whether tip stall could be prevented.

ON THE APPLICATION OF OBLIQUE COORDINATES TO PROBLEMS OF PLANE ELASTICITY AND SWEPT-BACK WING STRUCTURES. W. S. Hemp. WITH AN APPENDIX. S. R. Lewis. 1955. 46p. diagrs., tabs. (ARC R & M 2754; ARC 12,981. Supersedes College of Aeronautics Rept. 31; College of Aeronautics Rept. 44)

Methods are discussed by which designers can solve problems of stress distribution and deflection for the case of sweptback wing structures whose ribs lie parallel to the direction of flight. The mathematical basis is developed and formulas are derived. The results are applied to a uniform, symmetrical, rectangular section sweptback box. Theories of stress distribution and deflections are obtained for the case of loading by normal forces and couples applied to the ends of the box. The main results are then generalized to cover the case of a more representative wing structure. Functions useful in the application of the theory are given in an appendix.

LOW-SPEED TUNNEL MODEL TESTS ON TAIL-PLANE ROLLING MOMENTS IN SIDESLIP. A Spence, J. W. Leathers, and D. A. Kirby. 1955. 20p. diagrs., tabs. (ARC R & M 2941; ARC 14,701. Supersedes RAE Tech. Note Aero 2123)

Measurements were made of the effect of sideslip on the rolling moment on a 41.5° sweptback tail plane mounted at three heights on the fin of a model of a single jet aircraft with a 40° sweptback wing. Incidence and tail-plane setting were varied, and the effects of rudder deflection were obtained with the tail plane at the top of the fin. Brief results on a delta aircraft model with a delta tail plane at the top of the fin are also included. Values of the rolling moment on the tail plane were obtained from measurements of the bending moment on the starboard half of the tail plane about a hinge just outside the fin.

TWO-DIMENSIONAL CONTROL CHARACTERISTICS. L. W. Bryant, A. S. Halliday, and A. S. Batson. 1955. 47p. diagrs. (ARC R & M 2730. Supersedes ARC 13,039; S & C 2385; ARC 13,065; S & C 2386)

Researches on the lift, pitching moments, and hinge moments of airfoils with plain flaps have been carried out at the National Physical Laboratory at a Reynolds number of about 10^6. The results have been presented in a generalized form, which shows promise of being applicable over a wide field. It appears that a suggestion due to Preston that the ratio of experimental lift slope ($dC_L/d\alpha = a_1$) to the theoretical value $(a_1)_T$, corresponding to the Joukowsky condition of flow past the trailing edge, provides a criterion giving the combined effects of Reynolds number, transition points, and airfoil shape on $dC_L/d\alpha$, and is a very useful starting point for the estimation of control characteristics.

PERMISSIBLE DESIGN VALUES AND VARIABILITY TEST FACTORS. R. J. Atkinson. 1955. 20p. diagrs., tabs. (ARC R & M 2877; ARC 11,619; ARC 13,748. Supersedes RAE Tech. Note Structures 15; RAE Tech. Note Structures 61)

For the design of structural elements it is postulated that: not more than 10 percent of any given design should have strength below the design value, and not more than 0.1 percent should have strength below 90 percent of the design value. This rule forms a working basis for the interpretation of tests on statistical lines. On the basis of a fixed probability the report deduces: expressions for the derivation of permissible design values from a given number of test results, the number of test results required so that the estimates of permissible design values can be regarded as sufficiently accurate, and the factor which should be applied to the results of tests on any number of similar components designed to meet a specified requirement.

AN EXAMINATION OF THE FLOW AND PRESSURE LOSSES IN BLADE ROWS OF AXIAL-FLOW TURBINES. D. G. Ainley and G. C. R. Mathieson. 1955. 33p. diagrs. (ARC R & M 2891; ARC 14,232. Supersedes NGTE R. 86)

Available information is studied and analyzed to determine magnitudes of gas pressure losses and deflections in a wide variety of blade rows and to determine the separate influences of variables such as blade shape, blade spacing, gas Mach number, Reynolds number, incidence, etc. Special attention is paid to "secondary losses." Effects of blade tip clearance are also considered. Empirical guiding rules and charts are derived from which approximate values of the overall pressure losses and gas deflections in a range of blade rows can be deduced. It is found that secondary losses can in many instances be large, the loss being generally found to be great when the blading has low reaction.

FLUTTER AND RESONANCE CHARACTERISTICS OF A MODEL CANTILEVER WING CARRYING LOCALISED MASSES. N. C. Lambourne. 1955. 25p. diagrs., tabs. (ARC R & M 2866. Supersedes: ARC 13,910; 0.939; ARC 11,008; 0.687)

Resonance tests on a model cantilever wing carrying concentrated masses were made in conjunction with flutter tests. Measurements were made with masses up to approximately five times the mass of the bare wing added at two positions. Flutter and resonance characteristics are placed in juxtaposition. An attempt is made to correlate the two sets of phenomena by means of the Küssner criterion. Distortion modes of flutter are analyzed into normal mode components. Results suggest that for a wing rigidly fixed at the root and carrying a single concentrated mass the first three normal modes are sufficient to define the flutter mode.

THE APPLICATION OF THE EXACT METHOD OF AEROFOIL DESIGN. M. B. Glauert. 1955. 45p. diagrs., tabs. (ARC R & M 2683. Supersedes ARC 10,933; FM 1161)

This report considers in detail the design of airfoils by Lighthill's exact method, in which the velocity over the airfoil surface is prescribed as a function of the angular coordinate on the circle into which the airfoil may be transformed. The mathematical basis of the method is set out, means for obtaining desired characteristics for the airfoil are developed, and the procedure to be followed in the actual design is fully discussed. Various special functions are introduced to increase the range and practical utility of the velocity distributions obtainable, and these and other functions are fully tabulated. The calculations for the design of a particular thick suction airfoil are set out in detail.

AN EXPERIMENTAL INVESTIGATION OF THE BOUNDARY LAYER ON A POROUS CIRCULAR CYLINDER. D. G. Hurley and B(rian) Thwaites. 1955. 14p. diagrs., photos. (ARC R & M 2829. Supersedes ARC 14,158; FM 1584)

The report describes an experimental investigation of the boundary layer on the surface of a porous circular cylinder at which there is a normal inward velocity. The primary object of the experiments was to test the approximate theory of reference 1 for calculating the development of a laminar boundary layer under conditions of continuous suction. The formula given in that reference for calculating the momentum thickness of the layer gave results in accord with the experimental determinations. Owing to practical difficulties in the exploration of the very thin boundary layers and in the determination of the velocity gradient around the surface, other comparisons with the theory were difficult.

WIND-TUNNEL TESTS ON THE NACA 63A009 AEROFOIL WITH DISTRIBUTED SUCTION OVER THE NOSE. N. Gregory and W. S. Walker. 1955. 17p. diagrs., tabs. (ARC R & M 2900. Supersedes ARC 15,184; Perf. 987; FM 1787)

The effects of distributed suction on the stalling characteristics of the airfoil are described. The most economical extent of suction was from the leading edge for 2.75 percent chord round the upper surface. At a $R = 1.15 \times 10^6$, a suction-quantity coefficient of 0.0034 increased $C_{L_{max}}$ from 0.86 to 1.50 by delaying the stall from $\alpha = 11^o$ to $\alpha = 20^o$. Scale effect on the flow was investigated at $\alpha = 14^o$. The airfoil was also tested with a 20-percent split flap at 60° deflection. Suction gave half the increase on the flapped airfoil that it gave on the plain airfoil. The airfoil was modified for further testing by reducing the chord and blunting the nose.

Royal Aircraft Establishment (Gt. Brit.)
A UNIFIED THEORY OF PERFECTLY PLASTIC PLATES. E. H. Mansfield. May 1955. 53p. diagrs. (RAE Structures 170)

A theory is developed for determining the collapse load and the collapse mechanism for perfectly plastic plates under normal loading. A number of solutions to simple problems is first presented and the theory is extended to deal with plates of arbitrary plan carrying a concentrated load, and to plates of rectangular or regular polygonal plan carrying a uniformly distributed load.

INVESTIGATIONS INTO GLUES AND GLUING. PROGRESS REPORT EIGHTY-FIVE - JUNE 1955. BEHAVIOR OF GLUED WOOD PRODUCTS IN LIGHT NAVAL CRAFT. PART I - SYNOPTIC REPORT. FIFTH YEAR'S ANALYSIS. R. J. Newall and L. S. Doman. 6p. (Forest Products Research Lab. Supersedes corresponding part of Progress Report 71)

This investigation consists in storing samples of plywood and other glued wood products in selected locations for periods up to 10 years. At intervals, samples are removed and systematically tested for deterioration of the glue lines, fungal attack, etc. Inspections have been made at six-monthly intervals over the past 5 years and a summary of the observations is presented.

VELOCITY CALCULATIONS BY CONFORMAL MAPPING FOR TWO-DIMENSIONAL AEROFOILS.
D. A. Spence and N. A. Routledge. February 1955. 48p. diagrs., tabs. (RAE Aero 2539)

A method is derived for computing the conformal transformation between the plane of an airfoil of arbitrary shape (symmetrical or cambered), and the plane of its velocity potential at zero lift (in which the airfoil contour becomes a slit), in order to permit calculations of the velocity at points off the surface. The integral equation which relates the contours is derived by an application of Cauchy's theorem, and solved to the order of the square of thickness ratio. The solution is found by representing the ordinate distribution by a Fourier series. The rapid tailing-off of the Fourier coefficients for all smooth airfoil shapes then leads to high accuracy being achieved with a comparatively small amount of effort. The method is straightforward and has proved easy to use.

THE CHARACTERISTIC FREQUENCIES OF SMALL OSCILLATIONS IN THE FLOW PAST BLUFF BODIES. D. A. Spence. May 1955. 23p. diagrs. (RAE Aero 2532)

Summary: When a bluff body is placed in a steady stream it experiences buffeting, the periodicity of which can be explained in terms of interactions between external and boundary layer regions. It is shown that the frequency must satisfy a characteristic equation in order for the oscillations induced in the boundary layer to be compatible with those in the outside stream. The equation is derived formally for Lighthill's step case and for that of the circular cylinder. The Karman vortices which are observed in the latter case appear to be a consequence of the oscillatory character of the circulation around the cylinder.

NACA RM A54F28

ON THE RANGE OF APPLICABILITY OF THE TRANSONIC AREA RULE. John R. Spreiter. August 1954. 21p. (NACA RM A54F28) (Declassified from Confidential, 9/7/55)

Some insight into the range of applicability of the transonic area rule has been gained by comparison with the appropriate similarity rule of transonic flow theory and with experimental data for a large family of rectangular wings having NACA 63AXXX profiles.

NACA RM A54J07

THEORETICAL PRESSURE DISTRIBUTIONS FOR SOME SLENDER WING-BODY COMBINATIONS AT ZERO LIFT. Paul F. Byrd. January 1955. 39p. diagrs. (NACA RM A54J07) (Declassified from Confidential, 9/7/55)

Theoretical calculations are made of the pressure distributions for some slender, symmetrical wing-body combinations in subsonic and supersonic flow. The combinations consist first of nonlifting, swept-back wings mounted on a circular cylinder and second of such wings mounted on a body indented so that the local cross-sectional area of the combination is constant. The results indicate that indentation straightens out the isobars along the wing and diminishes the maximum perturbation velocities.

NACA RM L52H08

A STUDY OF THE ZERO-LIFT DRAG-RISE CHARACTERISTICS OF WING-BODY COMBINATIONS NEAR THE SPEED OF SOUND. Richard T. Whitcomb. September 1952. 41p. diagrs., photos., 3 tabs. (NACA RM L52H08) (Declassified from Confidential, 7/26/55)

Results are presented which indicate that near the speed of sound the zero-lift drag rise of a thin low-aspect-ratio wing-body combination is primarily dependent on the axial distribution of the cross-sectional areas normal to the airstream. Results of an investigation of applications of this concept to the reduction of the drag-rise increments of representative wing-body combinations are also presented.

NACA RM L54A29a

ON SLENDER-BODY THEORY AT TRANSONIC SPEEDS. Keith C. Harder and E. B. Klunker. March 1954. 12p. (NACA RM L54A29a) (Declassified from Confidential, 9/7/55)

The basic ideas of the slender-body approximation have been applied to the nonlinear transonic-flow equation for the velocity potential in order to obtain some of the essential features of slender-body theory at transonic speeds. The results of the investigation are presented from a unified point of view which demonstrates the similarity of slender-body solutions in the various Mach number ranges. The transonic area rule and some conditions concerning its validity follow from the analysis.

CURRENT NACA REPORTS

NACA Rept. 1191

ON THE DEVELOPMENT OF TURBULENT WAKES FROM VORTEX STREETS. Anatol Roshko, California Institute of Technology. 1954. ii, 25p. diagrs., photos., 3 tabs. (NACA Rept. 1191. Formerly TN 2913)

Wake development behind circular cylinders at Reynolds numbers from 40 to 10,000 was investigated by hot-wire techniques in a low-speed wind tunnel. The Reynolds number range of periodic vortex shedding is divided into two distinct subranges. In the stable range, R = 40 to 150, regular vortex streets are formed and no turbulent motion develops, the vortices decaying by viscous diffusion. The range R = 150 to 300 is a transition region to the irregular range in which turbulent velocity fluctuations accompany the periodic formation of vortices. The diffusion is turbulent and the wake becomes fully turbulent in 40 to 50 diameters. The turbulence is initiated by laminar-turbulent transition in the free layers which spring from the separation points on the cylinder. An annular vortex street was observed in the wake of a ring.

NACA RM E55E18

PERFORMANCE CHARACTERISTICS OF HEMISPHERICAL TARGET-TYPE THRUST REVERSERS. Fred W. Steffen, Jack G. McArdle, and James W. Coats. September 1955. 39p. diagrs., photos., tab. (NACA RM E55E18)

Reverse-thrust performance of hemispherical target-type thrust reversers was obtained. The value of reverse-thrust ratio was found to be primarily a function of hemisphere diameter. Slight improvements in performance were obtained with some size reversers by operating with the exhaust nozzle opened slightly. When high values of reverse-thrust ratio were obtained, the reversed flow attached to the boattail and the pressures on the boattail fell below atmospheric. This pressure reduction amounted to about 20 percent of the resultant reverse force. Various boattail shapes had little effect on reverse-thrust ratio for most hemisphere sizes.

NACA RM E55G27a

IDEAL TEMPERATURE RISE DUE TO CONSTANT-PRESSURE COMBUSTION OF A JP-4 FUEL. S(idney) C. Huntley. September 1955. 53p. diagrs., tabs. (NACA RM E55G27a)

Charts are presented from which ideal temperature rise or the ideal quantity of fuel required to obtain a specified combustion temperature may be obtained. The charts are applicable only to a fuel having a hydrogen-carbon mass ratio of 0.168 (CH_2) and include a range of fuel-air ratios from 0 to 1.2 fractions of stoichiometric fuel-air ratio with dissociation taken into account, inlet-air temperatures from 400° to 1600° R, and combustion pressures from 1/16 to 64 atmospheres.

NACA RM L55G21

NOTE ON HOVERING TURNS WITH TANDEM HELICOPTERS. John P. Reeder and Robert J. Tapscott. September 1955. 5p. photo. (NACA RM L55G21)

The source of an appreciable pitching-moment difference between left and right hovering turns for a tandem helicopter is described. The difference in pitching moment results from the difference in rotational speed of the counterrotating rotors with respect to the air while the helicopter is turning.

NACA TM 1377

THE THEORIES OF TURBULENCE. (Les Théories de la Turbulence). L. Agostini and J. Bass. October 1955. 163p. diagrs. (NACA TM 1377. Trans. from Ministère de l'Air, Publications Scientifiques et Techniques 237, 1950)

The report includes a discussion of the kinematics of statistical mediums, particularly those which are isotropic. A mathematical study is made of the applications of Navier's equations to turbulent motion. Physical theories involving similarity are dealt with. Review is made of much of the work in turbulence. The theoretical discussions are illustrated by some correlation and spectrum curves based on measurements taken in the wind tunnel at the laboratory of the mechanics of the atmosphere at Marseille.

NACA TM 1389

OPTIMUM FLIGHT PATHS OF TURBOJET AIRCRAFT. (Traiettorie Ottime Di Volo Degli Aeroplani Azionati Da Turboreattori). Angelo Miele. September 1955. 47p. diagrs., tabs. (NACA TM 1389. Trans. from L'Aerotecnica, v. 32, no. 4, 1952, p. 206-219)

The climb of turbojet aircraft is analyzed and discussed including the effects of tangential accelerations. Three flight performances are examined: minimum time of climb, climb with minimum fuel consumption, and steepest climb. Diagrams for quick calculation of the optimum Mach numbers and the effect of acceleration on the rate of climb in tropospheric and stratospheric flight are given.

NACA TM 1396

FROM LINEAR MECHANICS TO NONLINEAR MECHANICS. (De la mécanique linéaire a la mécanique non linéaire). Julien Loeb. October 1955. 18p. diagrs. (NACA TM 1396. Trans. from Annales des Télécommunications, v.5, no. 2, Feb., 1950, p. 65-71)

Consideration is first given to the technique used in telecommunication where a nonlinear system (the modulator) results in a linear transposition of a signal. It is then shown that a similar method permits linearization of electromechanical devices or nonlinear mechanical devices. A sweep function plays the same role as the carrier wave in radioelectricity. The linearizations of certain nonlinear functionals are presented.

NACA TN 3463

INVESTIGATION OF THE VIBRATIONS OF A HOLLOW THIN-WALLED RECTANGULAR BEAM. Eldon E. Kordes and Edwin T. Kruszewski. October 1955. 24p. diagrs., photos., 2 tabs. (NACA TN 3463)

Experimental modes and frequencies of an unstiffened hollow beam of rectangular cross section are presented, and comparisons are made between experimental and theoretical frequencies. Theories based on rigid cross sections were found to be sufficiently accurate to predict the frequencies of only the lowest three bending modes. For the higher bending modes and all the torsional modes, it was necessary to include the effects of cross-sectional distortions in the calculations.

NACA TN 3464

INFLUENCE OF SHEAR DEFORMATION ON THE CROSS SECTION ON TORSIONAL FREQUENCIES OF BOX BEAMS. Edwin T. Kruszewski and William W. Davenport. October 1955. 23p. diagrs. (NACA TN 3464)

An exact analysis has been carried out on the torsional vibrations of a four-flange box beam with cross sections which can change shape because the stiffness of the bulkheads is finite. The effect of shear deformation of the cross section on the torsional frequencies is illustrated by numerical calculations. An approximate method for quickly estimating the effects of bulkhead shear stiffness on the torsional frequencies of box beams has been devised.

NACA TN 3475

AN ANALYSIS OF ACCELERATION, AIRSPEED, AND GUST-VELOCITY DATA FROM ONE TYPE OF FOUR-ENGINE TRANSPORT AIRPLANE OPERATED OVER TWO DOMESTIC ROUTES. Martin R. Copp and Thomas L. Coleman. October 1955. 29p. diagrs., tabs. (NACA TN 3475)

Time-history data obtained by the NACA VGH recorder from one type of four-engine commercial transport airplane during operations on two domestic routes indicated that the number of gust accelerations experienced per mile of flight by the two operations differed by a factor of roughly 3. The number of gusts per mile of flight differed by a factor of roughly 4. A general decrease in the frequency of occurrence of gust velocities with increasing altitude was noted for both operations. For acceleration values above 0.8g, maneuver accelerations formed a substantial part of the total-flight load histories. A comparison of the average overall airspeeds and the corresponding average airspeeds in rough air (with accelerations equal to or greater than 0.3g) indicated very little slowdown by either operation upon encountering turbulence.

NACA TN 3481

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF EFFECT OF SIZE AND POSITION OF CLOSED AIR DUCTS ON STATIC LONGITUDINAL AND STATIC LATERAL STABILITY CHARACTERISTICS OF UNSWEPT-MIDWING MODELS HAVING WINGS OF ASPECT RATIO 2, 4, AND 6. Byron M. Jaquet and James L. Williams. September 1955. 45p. diagrs., photos., tabs. (NACA TN 3481)

Results are presented of tests made at a Mach number of 0.13 in the Langley stability tunnel to determine the effects of closed wing-root air ducts on the static longitudinal and static lateral stability characteristics of models having unswept wing and tail surfaces with wings of aspect ratio 2, 4, and 6. In addition, for model configurations employing the wing of aspect ratio 2 the effects of top and bottom fuselage ducts on the static longitudinal and static lateral characteristics were determined. The effect of the wing-root ducts on the aerodynamic hysteresis in sideslip of the model employing the wing of aspect ratio 2 was also determined.

NACA TN 3485

AN APPROXIMATE SOLUTION FOR AXIALLY SYMMETRIC FLOW OVER A CONE WITH AN ATTACHED SHOCK WAVE. Richard A. Hord. October 1955. 32p. diagrs. (NACA TN 3485)

It is shown that the streamlines in an angular neighborhood of the surface of an unyawed circular cone with an attached shock wave are, to a first approximation, portions of hyperbolas. This fact is used as a basis for the development of an approximate solution in which shock-wave orientation and flow field behind the shock wave are given explicitly in terms of free-stream Mach number, vertex angle of the body cone, and the ratio of specific heats of the gas. The approximate solution is compared with other approximate solutions for the cone.

NACA TN 3497

SUMMARY OF RESULTS OF A WIND-TUNNEL INVESTIGATION OF NINE RELATED HORIZONTAL TAILS. Jules B. Dods, Jr. and Bruce E. Tinling. July 1955. 105p. diagrs., 2 tabs. (NACA TN 3497. Formerly RM A51G31a)

A compilation of data is presented for models of nine related horizontal tails. The majority of the results were obtained at a Mach number of approximately 0.20. Three of the models were tested throughout the subsonic Mach number range to a maximum of 0.94. The Reynolds number range was from 2 to 4 million. The models had aspect ratios from 2 to 6, angles of sweepback from 5.7° to 45°, and had 30-percent-chord, sealed, plain flaps. The lift coefficient, hinge-moment coefficient, and pressure coefficients across the elevator nose seal are presented. The effects of sweepback, aspect ratio, and Mach number on the lift and hinge-moment parameters are summarized. Comparisons of the experimental results with theoretical calculations are presented.

NACA TN 3519

VISUALIZATION STUDY OF SECONDARY FLOWS IN TURBINE ROTOR TIP REGIONS. Hubert W. Allen and Milton G. Kofskey. September 1955. 33p. diagrs., photos., tab. (NACA TN 3519)

A low-speed visualization study of turbine rotor tip secondary flows was made. Results include qualitative information on tip-clearance flow, cross-passage flow, and scraping flow, and on a range of rotor speeds for which a transition condition appeared with minimum flow disturbance. Rotor speed required for this transition flow condition depended upon blade configuration, angle of incidence, tip clearance, and air-flow rate. Results should aid in extending the study to higher airspeeds.

NACA TN 3532

LOW-SPEED STATIC LATERAL AND ROLLING STABILITY CHARACTERISTICS OF A SERIES OF CONFIGURATIONS COMPOSED OF INTERSECTING TRIANGULAR PLAN-FORM SURFACES. David F. Thomas, Jr. October 1955. 29p. diagrs., photos. (NACA TN 3532)

The static lateral and rolling stability derivatives of a series of cruciform, inverted T-, V-, and Y-configurations composed of low-aspect-ratio triangular surfaces have been obtained at low speed in the 6-foot-diameter rolling-flow test section of the Langley stability tunnel. These derivatives are presented as functions of the geometry of the models, and for two configurations (a planar wing and an inverted T), as functions of angle of attack. Where possible, comparisons have been made to indicate the extent of agreement between experiment and existing theory. In general, the sideslip derivatives showed better agreement between theory and experiment than the rolling derivatives.

NACA TN 3533

THE PROPER COMBINATION OF LIFT LOADING FOR LEAST DRAG ON A SUPERSONIC WING. Frederick C. Grant. October 1955. 21p. diagrs. (NACA TN 3533)

Lagrange's method of undetermined multipliers is applied to the problem of properly combining lift loadings for the least drag at a given lift on supersonic wings. The interference drag between the optimum loading and any loading at the same lift coefficient is found to be constant on a given plan form. This is an integral form of a criterion established by Robert T. Jones for optimum loadings. The best combination of four loadings on a delta wing with subsonic leading edges is calculated for several Mach numbers as a numerical example.

NACA TN 3535

FLIGHT INVESTIGATION OF THE SURFACE-PRESSURE DISTRIBUTION AND THE FLOW FIELD AROUND A CONICAL AND TWO SPHERICAL NONROTATING FULL-SCALE PROPELLER SPINNERS. Jerome B. Hammack, Milton L. Windler, and Elwood F. Scheithauer. September 1955. 36p. diagrs., photos. (NACA TN 3535)

The surface-pressure distribution and the flow field around a conical and two spherical nonrotating full-scale propeller spinners were determined in flight at Mach numbers of 0.70 to 0.96. The local-surface Mach numbers between the cone-sphere tangency and the maximum thickness stations were approximately 0.4 higher than those at a free-stream Mach number of 0.95. The departure from free-stream conditions of the larger spherical spinner extends beyond the 1.3-spinner-radius station; whereas, with the smaller spherical spinner, free-stream conditions were reached at the 1.3-spinner-radius station.

NACA TN 3536

A LIMITED FLIGHT INVESTIGATION OF THE EFFECT OF THREE VORTEX-GENERATOR CONFIGURATIONS ON THE EFFECTIVENESS OF A PLAIN FLAP ON AN UNSWEPT WING. Garland J. Morris and Lindsay J(ohn) Lina. September 1955. 20p. diagrs., photos., tabs. (NACA TN 3536)

An exploratory flight investigation was made to determine the effect of three vortex-generator configurations on the effectiveness of the plain flap of a fighter airplane. Tests were made with flaps deflected 19° and 45° at several indicated airspeeds in the range from stall to 140 miles per hour. No improvement in flap effectiveness was obtained with the flaps deflected full down. With flaps deflected 19°, the vortex-generator configuration which produced the largest increase in lift coefficient had about the same effect as increasing the flap deflection to about 27°. Another configuration produced some increase in lift coefficient with no apparent increase in drag.

NACA TN 3538

SUMMARY OF DERIVED GUST VELOCITIES OBTAINED FROM MEASUREMENTS WITHIN THUNDERSTORMS. H(arold) B. Tolefson. October 1955. 19p. diagrs., tabs. (NACA TN 3538)

Available measurements of the derived gust velocities within thunderstorms are summarized for altitudes from 5,000 to 34,000 feet. The results indicate that the intensity of the derived gust velocity is essentially constant up to altitudes of 20,000 feet and that an approximate 10-percent reduction in the gust intensity occurs for altitudes from 20,000 to 30,000 feet.

NACA TN 3561

INTENSITY, SCALE, AND SPECTRA OF TURBULENCE IN MIXING REGION OF FREE SUBSONIC JET. James C. Laurence. September 1955. 58p. diagrs., photo., tab. (NACA TN 3561)

Hot-wire anemometer measurements of the turbulence parameters were made in a 3.5-inch-diameter free jet at exit Mach numbers between 0.2 and 0.7 and Reynolds numbers (based on jet rad.) between 37,500 and 350,000. The results of these measurements show that (1) the intensity of turbulence is a max. at a distance of approximately 1 jet rad. from the jet center line and decreases with increasing Mach and/or Reynolds number, and (2) the lateral and longitudinal scales of turbulence are nearly independent of Mach and/or Reynolds number and vary proportionally with distance from the jet nozzle. The lateral scale is much smaller than the longitudinal and does not vary with distance from the center line, while the longitudinal scale is a max. at a distance from the center line of about 0.7 to 0.8 of the jet rad.

NACA TN 3568

AVERAGING OF PERIODIC PRESSURE PULSATIONS BY A TOTAL-PRESSURE PROBE. R. C. Johnson. October 1955. 30p. diagrs., photo., tabs. (NACA TN 3568)

Information is presented on the average pressure indicated by a total-pressure probe subjected to a stagnation pressure that alternates periodically between two constant values. Calculated and experimental data are in good agreement, and errors are reduced when the probe design is such as to ensure laminar-flow pulsations in the probe at all times. The averaging error is minimized when the inside diameter of the probe entrance tube is made as small as possible, and its length as great as possible, consistent with an acceptable time lag.

NACA TN 3570

AN EXPERIMENTAL COMPARISON OF THE LAGRANGIAN AND EULERIAN CORRELATION COEFFICIENTS IN HOMOGENEOUS ISOTROPIC TURBULENCE. William R. Mickelsen. October 1955. 42p. diagrs. (NACA TN 3570)

The Lagrangian and Eulerian correlation coefficients were compared in a field of homogeneous, isotropic turbulence. The Lagrangian correlation coefficient was characterized by diffusion measurements, and the Eulerian coefficient was measured by hot-wire anemometry. The Lagrangian and Eulerian correlation coefficients had similar shapes connected by a linear relation between their coordinates. The proportionality factor in the linear relation was roughly constant over a range of turbulence intensities from 1.8 to 14 feet per second. The linear relation permits solution of mixing problems from the Eulerian turbulence parameters.

BRITISH REPORTS

N-38869*

Royal Aircraft Establishment (Gt. Brit.)
A SIMPLIFIED MODEL OF THE INCOMPRESSIBLE FLOW PAST TWO-DIMENSIONAL AEROFOILS WITH A LONG BUBBLE TYPE OF FLOW SEPARATION. J. F. Norbury and L. F. Crabtree. June 1955. 17p. diagrs., tabs. (RAE Tech. Note Aero 2352)

This problem may be divided into two parts. The first part concerns the external inviscid flow, and the other is related to the details of the flow inside the viscous region formed by the bubble, the boundary layer, and the wake. Although much information can be obtained by considering only the external stream (as in the hodograph method developed by Maskell), a complete and unique solution for the pressure distribution can only be found by attacking the second part of the problem as well. This has been attempted here and it is shown how the pressure recovery ratio at the end of a long bubble may be found by the analysis of a simplified model of the flow; the complete pressure distribution may then be uniquely determined.

NACA RM A8I17

INVESTIGATION OF A THIN WING OF ASPECT RATIO 4 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. III - THE EFFECTIVENESS OF A CONSTANT-CHORD AILERON. Ben H. Johnson, Jr., and Fred A. Demele. November 19, 1948. 26p. diagrs., photo. (NACA RM A8I17) (Declassified from Confidential, 9/15/55)

Presented in the report are results of tests at Mach numbers from 0.27 to 0.94 of a thin, unswept wing having a modified diamond airfoil section of thickness ratio 0.042 and equipped with a constant-chord aileron. The tests were conducted at a constant Reynolds number of 2,730,000. The effects of compressibility on the aileron effectiveness were negligible at Mach numbers up to 0.85, but at higher Mach numbers erratic effects of compressibility were evident, especially at lift coefficients greater than 0.5.

NACA RM A9I01

INVESTIGATION OF A THIN WING OF ASPECT RATIO 4 IN THE AMES 12-FOOT PRESSURE WIND TUNNEL. V - STATIC LONGITUDINAL STABILITY AND CONTROL THROUGHOUT THE SUBSONIC SPEED RANGE OF A SEMISPAN MODEL OF A SUPERSONIC AIRPLANE. Ben H. Johnson, Jr., and Francis W. Rollins. December 8, 1949. 130p. diagrs., photos. (NACA RM A9I01) (Declassified from Confidential, 9/15/55)

Presented in this report are results of tests at Mach numbers from 0.20 to 0.94 of a model of a hypothetical supersonic airplane equipped with a thin, sharp-edged wing and tail without sweep. The static longitudinal-stability characteristics of the model have been measured for two different vertical locations of the horizontal tail. The longitudinal control afforded by an all-movable stabilizer and by an elevator has been investigated. The downwash at the tail has been computed and the dynamic-pressure ratio at the tail has been evaluated from pressure measurements in the wake of the wing.

✓ NACA RM A51I07

THE STATIC LONGITUDINAL CHARACTERISTICS AT MACH NUMBERS UP TO 0.95 OF A TRIANGULAR-WING CANARD MODEL HAVING A TRIANGULAR CONTROL. Jack D. Stephenson and Ralph Selan. December 1951. 72p. diagrs., photo. (NACA RM A51I07) (Declassified from Confidential, 9/15/55)

Presents and analyzes results of tests to assess the longitudinal characteristics of a canard-type model having a triangular wing of aspect ratio 2 and NACA 0008-63 sections. The horizontal canard surface had a plan form identical to the wing and an NACA 0005-63 section. The Mach number range of the investigation varied from 0.25 to 0.95 at Reynolds numbers of 8 million and 3 million, respectively. The model was tested with the horizontal control surface at various fixed angles of incidence and with the surface unrestrained so that it could pivot about an axis at 30 percent of its mean aerodynamic chord.

NACA RM A52F18

THE LONGITUDINAL CHARACTERISTICS AT MACH NUMBERS UP TO 0.92 OF A CAMBERED AND TWISTED WING HAVING 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. George G. Edwards, Bruce E. Tinling, and Arthur C. Ackerman. September 1952. 71p. diagrs., photos., tab. (NACA RM A52F18) **(Declassified from Confidential, 9/15/55)**

A sweptback wing, in combination with a fuselage, of a type considered suitable for long-range, high-speed airplanes, has been tested in the Ames 12-foot pressure wind tunnel. The wing had 40° of sweepback, an aspect ratio of 10, a taper ratio of 0.4, and 5° of washout at the tip. The sections normal to the sweep reference line had NACA four-digit profiles, design lift coefficients of 0.40, and varied in thickness ratio from 14 percent at the root to 11 percent at the tip. The lift, drag, and pitching moment of a semispan model were measured at Reynolds numbers from 2,000,000 to 8,000,000 at low Mach numbers, and at Mach numbers from 0.25 to 0.92 at a Reynolds number of 2,000,000. The changes in boundary-layer flow on the upper surface were studied with tufts.

NACA RM A52I19

THE LONGITUDINAL CHARACTERISTICS AT MACH NUMBERS UP TO 0.9 OF A WING-FUSELAGE-TAIL COMBINATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. Bruce E. Tinling. December 1952. 41p. diagrs., photo., tab. (NACA RM A52I19) **(Declassified from Confidential, 9/15/55)**

Wind-tunnel tests were made of a wing-fuselage horizontal tail combination suitable for long-range high-speed airplanes. The cambered and twisted wing had an aspect ratio of 10, taper ratio of 0.4, and 40° sweepback. The all-movable horizontal tail had an aspect ratio of 4.5, taper ratio of 0.4, and 40° sweepback. Included are data on longitudinal stability and control, wing fence and tail effect, and isolated horizontal tail data. Data were obtained at a Reynolds number of 8,000,000 at low Mach numbers, and at a Reynolds number of 2,000,000 at Mach numbers up to 0.9.

NACA RM A52K20

PRESSURE DISTRIBUTION AT MACH NUMBERS UP TO 0.90 ON A CAMBERED AND TWISTED WING HAVING 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10, INCLUDING THE EFFECTS OF FENCES. Frederick W. Boltz and Harry H. Shibata. March 1953. 133p. diagrs., photos., tabs. (NACA RM A52K20) **(Declassified from Confidential, 9/15/55)**

Pressure-distribution measurements have been made on a semispan model of a cambered and twisted wing, alone and in combination with a fuselage. The wing had 40° of sweepback, an aspect ratio of 10, a taper ratio of 0.4, and 5° of washout at the tip. The wing thickness distribution in sections normal to the reference sweep line was the NACA 4-digit series with the maximum thickness varying from 14-percent chord at the root to 11-percent chord at the tip. The chordwise distributions of pressure coefficient at nine semispan stations are presented for Mach numbers of 0.165 and 0.25 at a Reynolds number of 8,000,000, and for Mach numbers from 0.25 to 0.90 at a Reynolds number of 2,000,000. Tabulated pressure data are presented for the wing without fences and with four fences.

NACA RM A53D06

THE EFFECTS OF NACELLES AND OF EXTENDED SPLIT FLAPS ON THE LONGITUDINAL CHARACTERISTICS OF A WING-FUSELAGE-TAIL COMBINATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. Bruce E. Tinling and Armando E. Lopez. June 1953. 47p. diagrs., tab. (NACA RM A53D06) **(Declassified from Confidential, 9/15/55)**

Wind-tunnel tests were made to evaluate the effects of nacelles and of extended split flaps on the longitudinal characteristics of a wing-fuselage-tail combination suitable for long-range high-speed airplanes. The cambered and twisted wing had an aspect ratio of 10, a taper ratio of 0.4, and 40° of sweepback. The nacelles were at 25 and 50 percent of the semispan. Data were obtained to evaluate the effects of nacelles at Mach numbers up to 0.90 at a Reynolds number of 2,000,000. The effects of the flaps were evaluated from data obtained at a Reynolds number of 4,000,000 and a Mach number of 0.082. A limited number of data were also obtained to evaluate the effects of increasing the tail height.

NACA RM A53I23

DOWNWASH BEHIND A TRIANGULAR WING OF ASPECT RATIO 3 - TRANSONIC BUMP METHOD. John A. Axelson. December 1953. 37p. diagrs., photo., tab. (NACA RM A53I23) **(Declassified from Confidential, 9/15/55)**

Downwash measured by means of an all-movable horizontal tail in several different locations is presented for a triangular wing having an aspect ratio of 3 and the NACA 63A006 section. The lift, drag, and pitching-moment characteristics of the wing and the downwash are presented for angles of attack up to 28° over a Mach number range from 0.6 to 1.1, corresponding to a Reynolds number range from 1.8 million to 2.4 million. The effects of tail location on the tail contribution to the static longitudinal stability of the wing-tail combination are discussed.

NACA RM A53I28

THE RESULTS OF WIND-TUNNEL TESTS AT LOW SPEEDS OF A FOUR-ENGINE PROPELLER-DRIVEN AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. George G. Edwards, Donald A. Buell, and Jerald K. Dickson. December 1953. 121p. diagrs., photo., tabs. (NACA RM A53I28) **(Declassified from Confidential, 9/15/55)**

The effects of operating propellers on the low-speed longitudinal characteristics of a four-engine tractor airplane configuration having a sweptback wing have been investigated in the Ames 12-foot pressure wind tunnel at thrust coefficients up to 0.9 per propeller and at Reynolds numbers from 4,000,000 to 8,000,000. Variations in the model included different heights and incidences of the horizontal tail as well as tail removed, two arrangements of extended split flaps, several propeller-blade angles, and independent as well as simultaneous operation of the inboard and outboard propellers. Coefficients of lift, longitudinal force, pitching moment, propeller thrust, and propeller power are presented in tabular form for various values of advance ratio at constant angles of attack. Selected portions of the data are presented in plotted form for various constant thrust coefficients.

NACA RM A53I29

THE TRANSONIC CHARACTERISTICS OF 36 SYMMETRICAL WINGS OF VARYING TAPER, ASPECT RATIO, AND THICKNESS AS DETERMINED BY THE TRANSONIC-BUMP TECHNIQUE. Warren H. Nelson, Edwin C. Allen, and Walter J. Krumm. December 1953. 131p. diagrs., photo. (NACA RM A53I29) **(Declassified from Confidential, 9/15/55)**

An investigation was made in the Ames 16-foot high-speed wind tunnel, utilizing the transonic-bump technique to determine the effects of plan-form taper on a series of wings having aspect ratios of 4, 3, and 2, and NACA 63A00X sections with thickness-to-chord ratios of 8, 6, 4, and 2 percent. The Mach number range was 0.6 to 1.1 with a corresponding Reynolds number range of about 1.4 million to 2.0 million. The results indicate that increasing the taper ratio caused only small increases in lift-curve slope except for the wings of highest aspect ratio and thinnest sections. Increasing taper ratio generally increased the overall center-of-pressure travel in going from subsonic to supersonic speeds.

NACA RM E8I01

EFFECT OF THREE FLAME-HOLDER CONFIGURATIONS ON SUBSONIC FLIGHT PERFORMANCE OF RECTANGULAR RAM JET OVER RANGE OF ALTITUDES. Dugald O. Black and Wesley E. Messing. November 24, 1948. 28p. diagrs., photo., tab. (NACA RM E8I01)
(Declassified from Confidential, 9/15/55)

A flight investigation is reported that was conducted on a rectangular ram jet incorporating various flame-holder configurations over a range of fuel-air ratios from 0.017 to 0.120, combustion-chamber-inlet velocities from 50 to 125 feet per second, and pressure altitudes from 1500 to 28,000 feet. Highest combustion efficiencies, which varied from a maximum of 82 percent at 1500 feet to 39 percent at 26,000 feet, were obtained at all altitudes with the three-V gutter-type flame holder. However, at any given altitude and fuel-air ratio slightly higher net-thrust coefficients occurred with the two-V flame holder as a result of its lower value of pressure drop.

NACA RM E8I28

EFFECT OF VARIATION IN FUEL PRESSURE ON COMBUSTION PERFORMANCE OF RECTANGULAR RAM JET. Wesley E. Messing and Dugald O. Black. November 24, 1948. 26p. diagrs., photo., tab. (NACA RM E8I28)
(Declassified from Confidential, 9/15/55)

Reports effect of variation in fuel pressure on starting characteristics, minimum blow-out limits, combustion efficiencies, gas total-temperature ratio, and net-thrust coefficient of rectangular ram jet operated over range of pressure altitudes from 1500 to 26,300 feet, indicated airspeeds from 100 to 200 miles per hour, and fuel-air ratios from 0.017 to 0.120. In general, increasing the degree of fuel atomization and distribution by utilization of small orifice fuel nozzles that operated at high fuel pressures resulted in higher values of combustion efficiency, gas total-temperature ratio, and net-thrust coefficient at a given fuel-air ratio.

NACA RM E50D28

AERODYNAMIC CHARACTERISTICS OF NACA RM-10 MISSILE IN 8- BY 6-FOOT SUPERSONIC WIND TUNNEL AT MACH NUMBERS FROM 1.49 TO 1.98. II - PRESENTATION AND ANALYSIS OF FORCE MEASUREMENTS. Fred T. Esenwein, Leonard J. Obery, and Carl F. Schueller. July 21, 1950. 34p. diagrs., photo. (NACA RM E50D28)
(Declassified from Confidential, 9/15/55)

Experimental investigation of aerodynamic forces acting on body of revolution (NACA RM-10 missile) with and without stabilizing fins was conducted at Mach numbers from 1.49 to 1.98 at angles of attack from 0° to 9° and at Reynolds number of approximately 30,000,000. Comparison of experimental lift, drag, and pitching-moment coefficients and center-of-pressure location for body alone is made with linearized potential theory and a semiempirical method. Results indicate that aerodynamic characteristics were predicted more accurately by semi-empirical method than by potential theory. Breakdown of measured drag coefficients into components of friction, pressure, and base-pressure drag is presented for body alone at zero angle of attack.

NACA RM E50I19

AERODYNAMIC CHARACTERISTICS OF NACA RM-10 MISSILE IN 8- BY 6-FOOT SUPERSONIC WIND TUNNEL AT MACH NUMBERS FROM 1.49 TO 1.98. III - ANALYSIS OF FORCE DISTRIBUTION AT ANGLE OF ATTACK (STABILIZING FINS REMOVED). Roger W. Luidens and Paul C. Simon. December 12, 1950. 26p. diagrs. (NACA RM E50I19)
(Declassified from Confidential 9/15/55)

Analysis of force distribution on slender pointed body of revolution at angle of attack was made utilizing pressure-distribution data and balance measurements obtained in NACA Lewis 8- by 6-foot supersonic tunnel. Comparison of experimental station normal force with those predicted by linearized potential theory (on which radius of body assumed to approach zero) shows that inaccurate prediction by theory of normal force acting on slender body of revolution with curved profiles at angle-of-attack results from inaccurate prediction of potential flow pressure distribution due to angle of attack, and from neglecting effect of cross-flow separation. Increase in total axial force with angle of attack was primarily due to increase in base pressure force.

NACA RM E51H23

WIRE CLOTH AS POROUS MATERIAL FOR TRANSPIRATION-COOLED WALLS. E. R. G. Eckert, Martin R. Kinsler, and Reeves P. Cochran. November 1951. 38p. diagrs., photos., tab. (NACA RM E51H23) **(Declassified from Confidential, 9/15/55)**

The permeability characteristics and tensile strength of a porous material developed from stainless-steel corduroy wire cloth for use in transpiration-cooled walls where the primary stresses are in one direction were investigated. The results of this investigation are presented and compared with similar results obtained with porous sintered metal compacts. A much wider range of permeabilities is obtainable with the wire cloth than with the porous metal compacts considered and the ultimate tensile strength in the direction of the primary stresses for porous materials produced from three mesh sizes of wire cloth is from two to three times the ultimate tensile strengths of the porous metal compacts.

NACA RM E52I12

INTERSTAGE SURVEYS AND ANALYSIS OF VISCOUS ACTION IN LATTER STAGES OF A MULTISTAGE AXIAL-FLOW COMPRESSOR. William B. Briggs and Charles C. Giamati. March 1953. 51p. diagrs., photo., tab. (NACA RM E52I12)
(Declassified from Confidential, 9/15/55)

The overall performance of an eight-stage axial-flow compressor having a design stage pressure ratio of 1.23 was determined and radial interstage surveys were made for four weight flows at both 50 percent and 100 percent design speed. The survey data, from behind the guide vanes and each row of the fifth to eighth stages, were presented as axial and tangential velocity components from which boundary-layer parameters of displacement and momentum thickness were calculated. An analysis related current qualitative ideas of flows which are imposed upon the through flow and the quantitative status of theory to the observed variation of these parameters. Midchannel velocity peaks in excess of design value were not found.

NACA RM E51I25

FLOW SEPARATION AHEAD OF A BLUNT AXIALLY SYMMETRIC BODY AT MACH NUMBERS 1.76 TO 2.10. W. E. Moeckel. December 1951. 12p. diagrs., photos. (NACA RM E51I25) **(Declassified from Confidential, 9/15/55)**

The pressure distribution and drag were determined for a spherical-nosed axially symmetric body with thin projecting rods at Mach numbers of 1.76, 1.93, and 2.10. The upstream projection distance of the rods was varied over a wide range to study changes in the character of the flow separation and to determine the variation of drag and pressure distribution with tip projection. Drag coefficients between 0.18 and 0.30 were obtained for most tip projections at each Mach number.

NACA RM L8I08

LONGITUDINAL-STABILITY INVESTIGATION OF HIGH-LIFT AND STALL-CONTROL DEVICES ON A 52° SWEPTBACK WING WITH AND WITHOUT FUSELAGE AND HORIZONTAL TAIL AT A REYNOLDS NUMBER OF 6.8×10^6. Gerald V. Foster and James E. Fitzpatrick. December 20, 1948. 41p. diagrs., photos., tabs. (NACA RM L8I08)
(Declassified from Confidential, 9/15/55)

Contains low-speed longitudinal stability characteristics of a 52° sweptback wing of aspect ratio 2.88, taper ratio 0.625, and NACA 64_1-112 airfoil sections normal to the 0.282-chord line, in combination with split flaps, leading-edge flaps, and upper-surface fences. Low-wing and midwing-fuselage aerodynamic characteristics are presented with and without a horizontal tail at various vertical locations. Tests were conducted at a Reynolds number of 6.8×10^6.

NACA RM L8I30a

EFFECTS OF A SWEPTBACK HYDROFOIL ON THE FORCE AND LONGITUDINAL STABILITY CHARACTERISTICS OF A TYPICAL HIGH-SPEED AIRPLANE. Raymond B. Wood. December 2, 1948. 19p. diagrs., photo., tabs. (NACA RM L8I30a)
(Declassified from Confidential, 9/15/55)

An investigation was conducted in the Langley 8-foot high-speed tunnel to determine the effects of a sweptback hydrofoil on the force and longitudinal stability

characteristics of a typical high-speed airplane. The Mach number range for this investigation was from 0.60 to 0.95 and at M = 1.20. The effects of the hydrofoil on the lift, drag, and pitching-moment characteristics are presented.

NACA RM L9I30

FLIGHT INVESTIGATIONS AT HIGH-SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS TO DETERMINE ZERO-LIFT DRAG OF FIN-STABILIZED BODIES OF REVOLUTION HAVING FINENESS RATIOS OF 12.5, 8.91, AND 6.04 AND VARYING POSITIONS OF MAXIMUM DIAMETER. Roger G. Hart and Ellis R. Katz. November 30, 1949. 36p. diagrs., photos. (NACA RM L9I30)
(Declassified from Confidential, 9/15/55)

Rocket-powered models were flown at transonic and supersonic speeds to determine the zero-lift drag of fin-stabilized bodies of revolution differing in fineness ratio and in position of maximum diameter. The bodies were of fineness ratio 12.5, 8.91, and 6.04 and all had cut-off sterns with equal base and frontal areas.

NACA RM L50I27

THE LONGITUDINAL STABILITY, CONTROL EFFECTIVENESS, AND CONTROL HINGE-MOMENT CHARACTERISTICS OBTAINED FROM A FLIGHT INVESTIGATION OF A CANARD MISSILE CONFIGURATION AT TRANSONIC AND SUPERSONIC SPEEDS. Roy J. Niewald and Martin T. Moul. November 24, 1950. 43p. diagrs., photos. (NACA RM L50I27)
(Declassified from Confidential, 9/15/55)

A 60° delta-wing canard missile configuration was flight-tested at the Langley Pilotless Aircraft Research Station at Wallops Island, Va. Longitudinal stability derivatives, control hinge-moment, and drag characteristics were obtained at transonic and supersonic velocities by utilizing a continuous step control disturbance of $\pm 5^{\circ}$.

NACA RM L51G31

SYSTEMATIC TWO-DIMENSIONAL CASCADE TESTS OF NACA 65-SERIES COMPRESSOR BLADES AT LOW SPEEDS. L. Joseph Herrig, James C. Emery, and John R. Erwin. September 1951. 223p. diagrs., photo., tabs. (NACA RM L51G31)
(Declassified from Confidential, 9/15/55)

A two-dimensional low-speed porous-wall cascade tunnel investigation has been conducted to establish the performance of the NACA 65-series compressor blade sections over the useful range of inlet angle, solidity, and section camber. Design points for optimum high-speed operation are presented. The loading limitation is determined for some conditions. Trends of section operating range with increasing section camber are determined for the four inlet angles tested.

NACA RM L51H03

ROLLING EFFECTIVENESS OF ALL-MOVABLE WINGS AT SMALL ANGLES OF INCIDENCE AT MACH NUMBERS FROM 0.6 TO 1.6. H. Kurt Strass and Edward T. Marley. October 1951. 16p. diagrs., photo., tab. (NACA RM L51H03)
(Declassified from Confidential, 9/15/55)

An investigation of the rolling effectiveness of several all-movable wing configurations has been conducted throughout a Mach number range from 0.6 to 1.6 in order to check a simplified wing incidence correction theory which states that for all-movable wing $\frac{pb}{2V} = \frac{2i_w}{57.3}\left(\frac{1+2\lambda}{1+3\lambda}\right)$. In addition, a comparison was made with two other more complex methods of estimation. The results showed that the simplified theory gave accurate agreement with experiment at Mach numbers from 0.6 to 1.6 and suggest the use of this simplified equation as a means of predicting the rolling effectiveness of all-movable wings throughout this speed range.

NACA RM L52I16

SOME EXPERIMENTAL STUDIES OF PANEL FLUTTER AT MACH NUMBER 1.3. Maurice A. Sylvester and John E. Baker. December 1952. 25p. diagrs., photos., tab. (NACA RM L52I16)
(Declassified from Confidential, 9/15/55)

Experimental studies of panel flutter using thin metal plates were conducted at a Mach number of 1.3 to verify its existence and to study the effects of some structural parameters on the flutter characteristics. The effects of tensile forces and buckling were studied on panels clamped front and rear, in addition to initially buckled panels clamped on all four edges. Panel flutter was obtained under these laboratory conditions and it was found that tensile forces, shortening the panels, and increasing the bending stiffness were effective means for eliminating flutter. Buckled panels were more susceptible to flutter than unbuckled panels. No apparent systematic trends in the flutter modes or frequencies could be observed.

NACA RM L53F17

METHOD OF ESTIMATING THE INCOMPRESSIBLE-FLOW PRESSURE DISTRIBUTION OF COMPRESSOR BLADE SECTIONS AT DESIGN ANGLE OF ATTACK. John R. Erwin and Laura A. Yacobi. December 1953. 41p. diagrs., tab. (NACA RM L53F17)
(Declassified from Confidential, 9/15/55)

A method was devised for estimating the incompressible flow pressure distribution over compressor blade sections at design angle of attack. The theoretical incremental velocities due to camber and thickness of the section as an isolated airfoil are assumed proportional to the average passage velocity and are modified by empirically determined interference factors. Comparisons were made between estimated and test pressure distributions of NACA 65-series sections for typical conditions. Good agreement was obtained.

NACA RM L53I11

FREE-FLIGHT-TUNNEL INVESTIGATION OF THE LOW-SPEED STABILITY AND CONTROL CHARACTERISTICS OF A CANARD AIRPLANE MODEL. Joseph L. Johnson, Jr., and John W. Paulson. October 1953. 37p. diagrs., photo., 2 tabs. (NACA RM L53I11) **(Declassified from Confidential, 9/15/55)**

Results are presented of an experimental investigation in the Langley free-flight tunnel to determine the dynamic lateral stability and control characteristics of a model of a canard-type airplane. Tests were made with several vertical-tail configurations for the model with a triangular horizontal tail and with a sweptback horizontal tail having a leading-edge flap.

NACA RM L53I25a

FLIGHT DETERMINATION OF DRAG OF NORMAL-SHOCK NOSE INLETS WITH VARIOUS COWLING PROFILES AT MACH NUMBERS FROM 0.9 TO 1.5. R. I. Sears, C. F. Merlet, and L. W. Putland. October 1953. 36p. diagrs., photos., tabs. (NACA RM L53I25a) **(Declassified from Confidential, 9/15/55)**

External-drag data are presented for normal-shock nose inlets with 1-series, parabolic, and conic cowling profiles. The tests were made at an angle of attack of 0° by using rocket-propelled models in free flight at Mach numbers from 0.9 to 1.5. The Reynolds number based on body maximum diameter varied from 2.5×10^6 to 5.5×10^6. At maximum flow rate, the inlet models had about the same external drag at a Mach number of approximately 1.1, but at higher Mach numbers the sharp-lip conic cowl had the least drag. Blunting or beveling the lip of the conic cowl while keeping the fineness ratio constant resulted in drag coefficients slightly higher than for the sharp-lip conic cowl at maximum flow rate. At a mass-flow ratio of about 0.8, the conic cowls with sharp, blunt, or beveled lips and the parabolic cowl all gave about the same drag.

NACA RM L53I29b

INVESTIGATION AT SUPERSONIC SPEEDS OF THE VARIATION WITH REYNOLDS NUMBER AND MACH NUMBER OF THE TOTAL, BASE, AND SKIN-FRICTION DRAG OF SEVEN BOATTAIL BODIES OF REVOLUTION DESIGNED FOR MINIMUM WAVE DRAG. August F. Bromm, Jr., and Julia M. Goodwin. December 1953. 20p. diagrs., photo. (NACA RM L53I29b) **(Declassified from Confidential, 9/15/55)**

Results are presented from an investigation of the variation with Reynolds number and Mach number of the total, base, and skin-friction drag of seven boattail bodies of revolution designed for minimum wave drag according to the theory of NACA TN 2550. The tests covered a Reynolds number range from approximately 1.0×10^6 to 10.0×10^6 at Mach numbers of 1.62, 1.93, and 2.41, respectively.

NACA RM L53I30b

TWO-DIMENSIONAL LOW-SPEED CASCADE INVESTIGATION OF NACA COMPRESSOR BLADE SECTIONS HAVING A SYSTEMATIC VARIATION IN MEAN-LINE LOADING. John R. Erwin, Melvyn Savage, and James C. Emery. November 1953. 129p. diagrs., tabs. (NACA RM L53I30b) **(Declassified from Confidential, 9/15/55)**

The low-speed cascade performance of the high-speed NACA 65-$\left(C_{l_o} A_2 I_{8b}\right)$10 compressor blade sections has been systematically investigated. When used in conjunction with published cascade data, the results will provide design information for all inlet angle and solidity conditions within the usual range of application. Summary curves have been prepared to facilitate the selection of blade sections and settings to fulfill the conditions dictated by compressor design velocity diagrams. Comparative tests of blade sections having widely different loading distributions indicated that these data, in conjunction with previously published cascade data, permit a fairly accurate prediction of design performance for most compressor blade sections since the mean lines tested probably encompass the practical range of compressor-blade mean-line loading distributions. A comparative evaluation of the high-speed performance capabilities of the blade sections investigated was made.

CURRENT NACA REPORTS

NACA Rept. 1175

EFFECT OF VARIABLE VISCOSITY AND THERMAL CONDUCTIVITY ON HIGH-SPEED SLIP FLOW BETWEEN CONCENTRIC CYLINDERS. T. C. Lin and R. E. Street, University of Washington. 1954. ii, 36p. diagrs. (NACA Rept. 1175. Formerly TN 2895)

The differential equations of slip flow, including the Burnett terms, were first solved by Schamberg assuming that the coefficients of viscosity and heat conduction of the gas were constants. The problem is solved herein for variable coefficients of viscosity and thermal conductivity by applying a transformation leading to an iteration method. The method, starting with the solution for constant coefficients, enables one to approximate the solution for variable coefficients very closely after one or two steps. Satisfactory results are shown to follow from Schamberg's solution by using his values of the constant coefficients multiplied by a constant factor η, leading to what are denoted as the effective coefficients of viscosity and thermal conductivity.

NACA Rept. 1189

THEORETICAL AND EXPERIMENTAL ANALYSIS OF LOW-DRAG SUPERSONIC INLETS HAVING A CIRCULAR CROSS SECTION AND A CENTRAL BODY AT MACH NUMBERS OF 3.30, 2.75, AND 2.45. Antonio Ferri and Louis M. Nucci. 1954. ii, 37p. diagrs., photos. (NACA Rept. 1189. Supersedes RM L8H13)

Contains theoretical and experimental analysis of circular inlets having a central body at Mach numbers of 3.30, 2.75, and 2.45. The inlets have been designed in order to have low drag and high pressure recovery. The pressure recoveries obtained are of the same order of magnitude as those previously obtained by inlets having very large external drag.

NACA Rept. 1198

A THEORETICAL STUDY OF THE EFFECT OF FORWARD SPEED ON THE FREE-SPACE SOUND-PRESSURE FIELD AROUND PROPELLERS. I. E. Garrick and Charles E. Watkins. 1954. ii, 16p. diagrs., tab. (NACA Rept. 1198. Supersedes TN 3018)

The sound-pressure field due to thrust and torque of a propeller in flight at uniform subsonic speed is analyzed by use of a distribution of acoustic doublets located at the propeller disk. The basic element used to synthesize the field is the pressure field of a concentrated force moving uniformly at subsonic speeds, for which an expression generalizing one of Lamb's for the fixed concentrated force is given. The results can be regarded as an extension of the work for the static propeller given by Gutin (NACA TM 1195) for the far pressure field and given by Hubbard and Regier (NACA Rep. 996) for the field near the tips of the rotating propeller. The extended formulas are used to calculate the sound field for a specific two-blade propeller operating at constant torque for various forward-speed Mach numbers.

NACA Rept. 1209

DEVELOPMENT OF TURBULENCE-MEASURING EQUIPMENT. Leslie S. G. Kovásznay, John Hopkins University. 1954. ii, 30p. diagrs., photos., tab. (NACA Rept. 1209. Supersedes TN 2839)

Hot-wire turbulence-measuring equipment has been developed to meet the more-stringent requirements involved in the measurement of fluctuations in flow parameters at supersonic velocities. The higher mean speed necessitates the resolution of higher frequency components than at low speed, and the relatively low turbulence level present at supersonic speed makes necessary an improved noise level for the equipment. The equipment covers the frequency range from 2 to 70,000 cycles per second. The equipment is adaptable to all-purpose turbulence work with improved utility and accuracy over that of older types of equipment. Sample measurements are given to demonstrate the performance.

NACA RM E55I16

SPARK IGNITION OF FLOWING GASES. V - APPLICATION OF FUEL-AIR-RATIO AND INITIAL-TEMPERATURE DATA TO IGNITION THEORY. Clyde C. Swett, Jr. November 1955. 19p. diagrs. (NACA RM E55I16)

Data showing the effect of fuel-air ratio and initial temperature on spark-ignition energy are presented and applied to a previously developed theory of ignition. The initial-temperature data are consistent with the theory; fuel-air-ratio data are only partially consistent. Probable reasons for the discrepancy are discussed.

NACA TM 1388

GENERAL SOLUTIONS OF OPTIMUM PROBLEMS IN NONSTATIONARY FLIGHT. (Soluzioni Generali di Problemi di Ottimo in Volo Non-Stazionario). Angelo Miele. October 1955. 25p. diagrs., tab. (NACA TM 1388. Trans. from L'Aerotecnica, v.32, no.3, 1952, p.135-142)

A general method concerning optimum problems in nonstationary flight is developed and discussed. Various conditions of flight in a vertical plane (climb with minimum time, climb with minimum fuel consumption, steepest climb, descending and gliding flight with maximum time of space) are studied; the corresponding best techniques of flight, that is, the optimum speed-height relationships, are determined.

NACA TN 3415

A UNIVERSAL COLUMN FORMULA FOR LOAD AT WHICH YIELDING STARTS. L. H. Donnell and V. C. Tsien, Illinois Institute of Technology. October 1955. 48p. diagrs., photos., tab. (NACA TN 3415)

An analysis is presented of the load at which yielding first occurs in actual columns, taking adequately into account all the factors which have an important effect upon this load. The results are expressed as a formula or chart applicable to all cases.

NACA TN 3476

CALCULATED SPANWISE LIFT DISTRIBUTIONS AND AERODYNAMIC INFLUENCE COEFFICIENTS FOR SWEPT WINGS IN SUBSONIC FLOW. Franklin W. Diederich and Martin Zlotnick. October 1955. 173p. diagrs., tabs. (NACA TN 3476)

Spanwise lift distributions have been calculated for 61 swept wings with various aspect ratios and taper ratios and with a variety of angle-of-attack or twist distributions, including flap and aileron deflections, by means of the Weissinger method with eight control points on the semispan. Also calculated were aerodynamic influence coefficients which pertain to a certain definite set of stations along the span.

NACA TN 3494

SOUND PROPAGATION INTO THE SHADOW ZONE IN A TEMPERATURE-STRATIFIED ATMOSPHERE ABOVE A PLANE BOUNDARY. David C. Pridmore-Brown and Uno Ingard, Massachusetts Institute of Technology. October 1955. 57p. diagrs., photo. (NACA TN 3494)

A theoretical and experimental study of the sound field about a point source over a plane boundary in the presence of a vertical temperature gradient has been made. Methods are presented for analyzing the effects of temperature gradients on the attenuation of sound in the shadow zone of a sound field.

NACA TN 3495

FAILURE OF MATERIALS UNDER COMBINED REPEATED STRESSES WITH SUPERIMPOSED STATIC STRESSES. George Sines, University of California at Los Angeles. November 1955. 69p. diagrs., photos., tabs. (NACA TN 3495)

Experiments on biaxial alternating stresses and simple combinations of static stress with alternating stress are reviewed. A general criterion for the effect of static stress on the permissible amplitude of alternating stress is proposed and compared with results of tests performed under more complex stress states. Tests were performed to determine the effect of static compression on alternating torsion and the results are compared with the general criterion. A modification of Orowan's theory of fatigue to include the effect of static stress is presented.

NACA TN 3531

PILOT'S LOSS OF ORIENTATION IN INVERTED SPINS. Stanley H. Scher. October 1955. 10p. diagrs., photos. (NACA TN 3531)

The rising problem of pilot orientation during spins, especially during unintentional inverted spins, is discussed. The free-spinning-tunnel results and reported airplane experiences concerning inverted spins and recoveries are reviewed. Information is provided regarding the nature of inverted spins, optimum control technique for recovery, and some of the factors which apparently contribute to the pilot's loss of orientation. A spin-simulator rig which was recently constructed at the Langley Laboratory for use in an attempt to understand better the problems confronting the pilot of a spinning airplane is described.

NACA TN 3537

HELICOPTER INSTRUMENT FLIGHT AND PRECISION MANEUVERS AS AFFECTED BY CHANGES IN DAMPING IN ROLL, PITCH, AND YAW. James B. Whitten, John P. Reeder, and Almer D. Crim. November 1955. 14p. diagrs., photos. (NACA TN 3537)

The damping in roll, pitch, and yaw of a single-rotor helicopter was varied by means of electronic components, and these variations were evaluated by performing instrument approaches and other precision maneuvers. Increased damping in roll was found to be particularly beneficial, whereas corresponding changes in yaw and pitch were less effective. Some operational aspects of helicopter instrument approaches are also included in the discussion.

NACA TN 3539

SOME EFFECTS OF SYSTEM NONLINEARITIES IN THE PROBLEM OF AIRCRAFT FLUTTER. Donald S. Woolston, Harry L. Runyan, and Thomas A. Byrdsong. October 1955. 20p. diagrs., tabs. (NACA TN 3539)

This paper presents the results of a preliminary investigation of the effect of nonlinear structural terms on the flutter of a two-degree-of-freedom system. The three types of nonlinearities investigated were a flat spot, hysteresis, and a cubic spring. Calculations were made on an analog computer. For one case, the flat spot, an experimental investigation was also made and good correlation with theory was found.

NACA TN 3542

ANALYSIS OF STRESSES IN THE PLASTIC RANGE AROUND A CIRCULAR HOLE IN A PLATE SUBJECTED TO UNIAXIAL TENSION. Bernard Budiansky and Robert J. Vidensek. October 1955. 39p. diagrs., tabs. (NACA TN 3542)

An approximate theoretical solution is presented for the stresses in the plastic range around a circular hole in an infinite sheet subjected to uniaxial tension. The solution is based on the simple deformation theory of plasticity and is found by application of a variational principle in conjunction with the Rayleigh-Ritz procedure and the use of a high-speed computing machine (SEAC). Numerical results are obtained for four different materials, which are characterized by four distinct uniaxial stress-strain curves. The results for stress concentration factor in the plastic range are compared with those obtained from a formula due to Stowell.

NACA TN 3544

COMPARISON BETWEEN THEORETICAL AND EXPERIMENTAL STRESSES IN CIRCULAR SEMIMONOCOQUE CYLINDERS WITH RECTANGULAR CUTOUTS. Harvey G. McComb, Jr., and Emmet F. Low, Jr. October 1955. 20p. diagrs. (NACA TN 3544)

Comparisons are made between a theory for calculating stresses about rectangular cutouts in circular cylinders of semimonocoque construction published in NACA TN 3200 and previously published NACA experimental data. The comparisons include stresses in the stringers and shear stresses in the center of the shear panels in the neighborhood of the cutout. The theory takes into account the bending flexibility of the rings in the structure, and this factor is found to be important in the calculation of stresses about cutouts. In general, when the ring flexibility is considered, good agreement is exhibited between the calculated and experimental results.

NACA TN 3550

MEASUREMENTS OF THE EFFECT OF TRAILING-EDGE THICKNESS ON THE ZERO-LIFT DRAG OF THIN LOW-ASPECT-RATIO WINGS. John D. Morrow. November 1955. 11p. diagrs., photo. (NACA TN 3550. Supersedes RM L50F26)

Results of an exploratory free-flight investigation at zero lift of several rocket-powered drag-research models having 4-percent-thick wings of taper ratio 0.423 are presented for a Mach number range of 0.7 to 1.6. Four wings having trailing edges of different thicknesses were tested. The drag of all the models was measured and is compared with calculated values.

NACA TN 3557

A THEORETICAL ANALYSIS OF THE FIELD OF A RANDOM NOISE SOURCE ABOVE AN INFINITE PLANE. Peter A. Franken, Massachusetts Institute of Technology. November 1955. 20p. diagrs. (NACA TN 3557)

The sound field about a random noise source above a plane as measured by a receiver with finite band width is studied theoretically. For simplicity, only the far field is considered. The special case of a perfectly reflecting plane is discussed first and the analysis is then extended to include the case of a plane of arbitrary impedance.

NACA TN 3567

STUDY OF SCREECHING COMBUSTION IN A 6-INCH SIMULATED AFTERBURNER. Perry L. Blackshear, Warren D. Rayle, and Leonard K. Tower. October 1955. 58p. diagrs., photos., tab. (NACA TN 3567)

The mode of oscillation in a screeching 6-inch-diameter simulated afterburner is identified through axial, circumferential, and diametric surveys of sound amplitude and phase. This mode is found to be the first transverse (sloshing) mode in the hot gases downstream of the flame-holder. The development of a microphone probe suitable for use in screeching combustors is described. This development includes a theoretical and experimental treatment of the attenuation of high-amplitude sound in tubes.

NACA TN 3572

AMPLITUDE OF SUPERSONIC DIFFUSER FLOW PULSATIONS. William H. Sterbentz and Joseph Davids. October 1955. 23p. diagrs. (NACA TN 3572. Supersedes RM E52I24)

A theoretical method for evaluating the stability characteristics and the amplitude and frequency of pulsation of ram-jet engines without heat addition is presented. Theory and experiment show that the pulsation amplitude of a high-mass-flow-ratio diffuser increases with decreasing mass flow. The theoretical trends for changes in amplitude, frequency, and mean pressure recovery with changes in plenum-chamber volume were experimentally confirmed. For perforated, convergent-divergent-type diffusers, theory and experiment show the existence of a stability hysteresis loop on the pressure-recovery, mass-flow-ratio curve.

NACA TN 3573

EFFECT OF EXHAUST-NOZZLE EJECTORS ON TURBOJET NOISE GENERATION. Warren J. North and Willard D. Coles. October 1955. 26p. diagrs., photo. (NACA TN 3573)

Engine noise levels and jet velocity profiles have been obtained with several turbojet exhaust-nozzle ejectors. An insignificant reduction in total sound power was realized. At subsonic nozzle pressure ratios, total sound power from exhaust-nozzle ejectors or bypass exit configurations can be calculated from primary-jet parameters only.

NACA TN 3575

BURNING VELOCITIES OF VARIOUS PREMIXED TURBULENT PROPANE FLAMES ON OPEN BURNERS. Paul Wagner. October 1955. 32p. diagrs., photos., tab. (NACA TN 3575)

Turbulent burning velocities were measured as a function of Reynolds number for open propane flames. Flames of propane and oxygen diluted with nitrogen, argon, or helium were studied in a variety of burners up to a maximum pipe Reynolds number of 26,000. The ratio of turbulent to laminar burning velocity correlates with the cold-flow Reynolds number for systems of a given diluent. This ratio also correlates with a Reynolds number calculated from values of the turbulent intensity measured at the burner exit.

TESTS ON HEAT AND CORROSION RESISTING COATINGS FOR MAGNESIUM ALLOYS. J. Mackay and H. G. Cole. June 1955. 9p. tabs. (RAE Tech. Note Chem. 1254)

In tests on painted magnesium alloy specimens heated to 200° C at three-monthly intervals during an intermittent seawater spray test, the best combinations of protective efficiency with hardness and flexibility were given by an epoxy base scheme and by a standard stoving scheme to D. T. D. 235. Other epoxy schemes gave good protection but were relatively inflexible. A standard air-drying scheme to D. T. D. 260A gave very good protection. Butyl titanate paints and a silicone paint gave poor protection. A zinc chrome sealed anodic treatment gave better results as a protective pretreatment than chromate bath iii of D. T. D. 911A. Butyl titanate paints broke down on pure aluminum exposed to the same test.

HEAT-RESISTANT SINTER MATERIALS. (Hochwarmfeste Sinterwerkstoffe). F. Benesovsky. (1955). 6p. diagrs., photo., tab. (Trans. from Werkstoffe und Korrosion, Jour., no. 8/9, Aug. - Sept. 1954, p. 288-290)

Ceramal materials, produced by powder metallurgy from a titanium carbide base, are suggested for use in turbine and rocket drives. Other ceramal materials suggested for high temperature use are alloys with boride, silicide, and oxide bases. Titanium boride and zirconium boride show high melting points, are generally brittle, and have poor thermal shock properties. It is believed that metal additions may improve these properties.

DECLASSIFIED NACA REPORTS

V - we have

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM CONFIDENTIAL, 10/14/55

NACA RM A7J02

THE HIGH-SPEED AERODYNAMIC EFFECTS OF MODIFICATIONS TO THE WING AND WING-FUSELAGE INTERSECTION OF AN AIRPLANE MODEL WITH THE WING SWEPT BACK 35°. Lee E. Boddy and Charles P. Morrill, Jr. February 18, 1948. 34p. diagrs., photos. (NACA RM A7J02)

Wind-tunnel tests at high subsonic Mach numbers were conducted on an airplane model having sweptback wings. Attempts were made to reduce the interference at the plane of symmetry of the sweptback wing and thus increase its divergence Mach number. Also, tests were made with the wing trailing-edge angle decreased, in an effort to eliminate the reversal of aileron hinge moment and wing pitching moment suffered by the true-contour wing at high Mach numbers.

NACA RM A7J03

THE AERODYNAMIC EFFECTS OF ROCKETS AND FUEL TANKS MOUNTED UNDER THE SWEPTBACK WING OF AN AIRPLANE MODEL. Lee E. Boddy and Charles P. Morrill, Jr. April 23, 1948. 19p. diagrs. (NACA RM A7J03)

The effects of externally mounted rockets and fuel tanks on the aerodynamic characteristics of an airplane model with sweptback wings are presented in this report. Wind-tunnel tests were made at high subsonic Mach numbers to determine the effect of the external equipment on the drag, the longitudinal stability and control, and the lateral control of the model.

NACA RM A50J26

EXPERIMENTAL DAMPING IN PITCH OF 45° TRIANGULAR WINGS. Murray Tobak, David E. Reese, Jr., and Benjamin H. Beam. December 1, 1950. 63p. diagrs., photo. (NACA RM A50J26)

Results are presented of a wind-tunnel investigation of the variation of the damping-in-pitch parameter $C_{m_q} + C_{m_{\dot{\alpha}}}$ with Mach number and axis of rotation position for two triangular wings having leading edges swept back 45°, with and without a body. Tests were conducted at subsonic speeds over a Mach number range of 0.23 to 0.94 and at supersonic speeds from 1.15 to 1.70. The measured damping coefficients are compared with theoretical results at both subsonic and supersonic speeds.

✓ NACA RM A53J02

PRELIMINARY RESULTS OF AN INVESTIGATION OF THE EFFECTS OF SPINNER SHAPE ON THE CHARACTERISTICS OF AN NACA D-TYPE COWL BEHIND A THREE-BLADE PROPELLER, INCLUDING THE CHARACTERISTICS OF THE PROPELLER AT NEGATIVE THRUST. Robert M. Reynolds. November 1953. 15p. diagrs., photo., tab. (NACA RM A53J02)

Preliminary results of measurements of the ram-recovery ratio at the inlet of an NACA D-type cowl behind an operating propeller in combination with a 1-series and a modified-conical spinner, maximum efficiency of the propeller with the 1-series spinner and the spinner-cowling combinations, and the negative thrust characteristics of the propeller at low speeds are summarized. Tests were conducted at Mach numbers from 0.2 to 0.8, for propeller blade angles from 33° to 63°, and for various inlet-velocity and advance ratios. Negative-thrust characteristics of the propeller were measured at a Mach number of 0.15 for blade angles from 25° to -20°. All tests were made with the model at an angle of attack of 0° and at a Reynolds number of 1.0 million per foot.

NACA RM A53J07

THE EFFECTS OF HORIZONTAL-TAIL HEIGHT AND A PARTIAL-SPAN LEADING-EDGE EXTENSION ON THE STATIC LONGITUDINAL STABILITY OF A WING-FUSELAGE-TAIL COMBINATION HAVING A SWEPTBACK WING. Angelo Bandettini and Ralph Selan. March 1954. 54p. diagrs., photos., 2 tabs. (NACA RM A53J07)

Test results are presented to show the effects of horizontal-tail height (22- and 8-percent semispan above wing chord plane extended) on the static longitudinal stability of a model having a wing with 35° sweepback, an aspect ratio 4.5, and a taper ratio 0.5. The model was also modified by a wing-leading-edge chord extension and tested with the tail in the low position. Tests were conducted at various Mach numbers up to 0.92 at a Reynolds number of 2,000,000 and at a Mach number of 0.20 at a Reynolds number of 11,000,000. The results of airstream surveys in the region of the tail are also presented.

NACA RM E50J24

DYNAMIC INVESTIGATION OF TURBINE-PROPELLER ENGINE UNDER ALTITUDE CONDITIONS. Richard P. Krebs, Seymour C. Himmel, Darnold Blivas, and Harold Shames. December 6, 1950. 55p diagrs., photo. (NACA RM E50J24)

An altitude-wind-tunnel investigation of the dynamics of a turbine-propeller engine employing the frequency-response technique was conducted over a range of pressure altitudes from 10,000 to 30,000 feet. The dynamic responses generalized for pressure altitudes over the range of frequencies investigated. The generalized time constants were found to be approximately 1.0 second for the engine-propeller combination, 0.36 second for the propeller alone, and 2.4 seconds for the engine alone. These values were in good agreement with those predicted from steady-state-performance data.

NACA RM E51J11

IGNITION-DELAY CHARACTERISTICS IN MODIFIED OPEN-CUP APPARATUS OF SEVERAL FUELS WITH NITRIC ACID OXIDANTS WITHIN TEMPERATURE RANGE 70° TO -105° F. Riley O. Miller. December 1951. 30p. diagrs., 4 tabs. (NACA RM E51J11)

Fluid properties and low-temperature ignition delays were obtained for approximately 90 fuel-oxidant combinations. A red fuming nitric acid containing approximately 3 percent water and 19 percent nitrogen tetroxide froze at approximately -87° F and ignited several low-viscosity fuel blends of aromatic amines in triethylamine at -76° F and lower. With this acid, the following average ignition delays were obtained with a blend of 30 percent o-toluidine in triethylamine:

Temperature, °F	70	-40	-76	-87	-105
Delay, milliseconds	19	24	38	61	210

NACA RM E52J27

PRELIMINARY INVESTIGATION OF A PERFORATED AXIALLY SYMMETRIC NOZZLE FOR VARYING NOZZLE PRESSURE RATIOS. Eli Reshotko. January 1953. 43p. diagrs., photo., 2 tabs. (NACA RM E52J27)

The performance characteristics of a perforated axially symmetric convergent-divergent nozzle were investigated in an attempt to achieve improved convergent-divergent nozzle thrust performance at below design pressure ratios. The purpose of the perforations was to allow inflow of air into the overexpanded portion of the nozzle, thus advancing separation of the flow. The flow through the perforations was found to advance separation only when the perforations were liberally placed over the entire divergent portion of the nozzle. A local concentration of perforations caused separation only in the local region of perforation. The use of low energy atmospheric bleed air reduced thrust losses by as much as 50 percent at appreciably overexpanded operation. For underexpanded flow, air flowing out through the perforations caused significant thrust loss. With shrouding to prevent this outbleed, thrusts 5 to 10 percent less than those of the unperforated nozzle were obtained. The use of high energy bleed was unsatisfactory since the inlet momentum penalty of the bleed air was in many cases greater than the additional thrust obtained.

NACA RM L8I29

PRELIMINARY RESULTS OF NACA TRANSONIC FLIGHTS OF THE XS-1 AIRPLANE WITH 10-PERCENT-THICK WING AND 8-PERCENT-THICK HORIZONTAL TAIL. Hubert M. Drake, Harold R. Goodman, and Herbert H. Hoover. October 13, 1948. 18p. diagrs., photos. (NACA RM L8I29)

Contains results of exploratory flights at altitudes of about 40,000 feet to a maximum Mach number of 1.06. Data are presented showing the longitudinal trim changes, elevator effectiveness in producing acceleration, and rudder effectiveness as a function of Mach number. Data on lateral oscillations are also presented.

NACA RM L8J12

HIGH-SPEED WIND-TUNNEL INVESTIGATION OF A SWEPTBACK WING WITH AN ADDED TRIANGULAR AREA AT THE CENTER. Beverly Z. Henry, Jr. January 14, 1949. 24p. diagrs., tabs. (NACA RM L8J12)

Results are presented of an investigation in the Langley 8-foot high-speed tunnel of two sweptback wings of different plan form. The purpose of the investigation was to determine the effects of the addition of a triangular area to the inboard section of a conventional sweptback wing in order to produce a wing employing two stages of sweepback. Lift, drag, and pitching-moment characteristics are presented to illustrate these effects for a Mach number range of 0.40 through 0.935.

NACA RM L8K23

FREE-FLIGHT INVESTIGATION AT TRANSONIC AND SUPERSONIC SPEEDS OF THE ROLLING EFFECTIVENESS OF SEVERAL AILERON CONFIGURATIONS ON A TAPERED WING HAVING 42.7° SWEEPBACK. Carl A. Sandahl. January 11, 1949. 23p. diagrs., photos., tab. (NACA RM L8K23)

An investigation was made of several aileron modifications in conjunction with a tapered, sweptback wing having circular-arc airfoil sections of relatively large thickness ratio. The modified ailerons eliminated the reversal of rolling effectiveness at transonic speeds obtained with the true-contour ailerons at small deflections.

NACA RM L9F07

PRELIMINARY THEORETICAL AND FLIGHT INVESTIGATION OF THE LATERAL OSCILLATION OF THE X-1 AIRPLANE. Hubert M. Drake and Helen L. Wall. July 19, 1949. 24p. diagrs., photo., tab. (NACA RM L9F07)

A small-amplitude, undamped, lateral oscillation has been encountered in flight tests of the X-1 airplane. The oscillation occurs in subsonic and supersonic flight, in maneuvers, and power on and off. The calculations indicate that a change, in the positive direction, of the inclination of the principal axis with respect to the flight path should have a considerable stabilizing effect.

NACA RM L9G19a

MEASUREMENTS OF AILERON EFFECTIVENESS OF THE BELL X-1 AIRPLANE AT MACH NUMBERS BETWEEN 0.9 AND 1.06. Hubert M. Drake. August 4, 1949. 5p. diagrs. (NACA RM L9G19a)

Presents results of flight measurements of aileron effectiveness of the X-1 airplane up to a Mach number of 0.94. The data indicate a 75 percent loss of aileron effectiveness between $M = 0.82$ and $M = 0.94$.

NACA RM L50G20

ELEVATOR-STABILIZER EFFECTIVENESS AND TRIM OF THE X-1 AIRPLANE TO A MACH NUMBER OF 1.06. Hubert M. Drake and John R. Carden. November 1, 1950. 12p. diagrs. (NACA RM L50G20)

The relative elevator-stabilizer effectiveness of the X-1 has been determined to decrease from a value of 0.25 at a Mach number of 0.78 to a value of 0.05 at a Mach number of 1.0. At supersonic speeds the effectiveness increases. The variation between the trim curves at various stabilizer settings is caused by the variation in effectiveness and the fact that the effectiveness is nonlinear at Mach numbers between 0.94 and 0.97. It was found that, with the elevator fixed at zero, only about 0.5° of stabilizer movement would be required to trim through the Mach number range from 0.78 to 1.02.

NACA RM L50J25

A TRANSONIC-WING INVESTIGATION IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL AT HIGH SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. WING-FUSELAGE CONFIGURATION HAVING A WING OF 60° SWEEPBACK, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. Raymond B. Wood and Frank F. Fleming. January 24, 1951. 43p. diagrs., photo. (NACA RM L50J25)

An investigation was conducted in the Langley 8-foot high-speed tunnel of the aerodynamic characteristics of a wing swept back 60° at the quarter chord, with aspect ratio 4, taper ratio 0.6, and an NACA 65A006 airfoil section. The tests were conducted through a Mach number range from 0.6 to 0.96 and at a Mach number of 1.2. Data are presented for a wing fuselage and for a wing with wing-fuselage interference. Wake-survey-study results and the measurements of the angle of downwash for a probable tail location, approximately 38 percent of the wing semispan above the wing-chord plane, are included.

NACA RM L51D17

AN INVESTIGATION OF FOUR WINGS OF SQUARE PLAN FORM AT A MACH NUMBER OF 6.86 IN THE LANGLEY 11-INCH HYPERSONIC TUNNEL. Charles H. McLellan, Mitchel H. Bertram, and John A. Moore. June 1951. 47p. diagrs., photos. (NACA RM L51D17)

The results of tests of four wings at a Mach number of 6.86 in the Langley 11-inch hypersonic tunnel are presented. The wings tested had 4-inch square plan forms with 5-percent-thick diamond, half-diamond, wedge, and half-circular-arc sections. The boundary layer has been found to have a large effect on the wing pressure distributions. Reasonable agreement was indicated between the aerodynamic coefficients from experimental pressure data and inviscid theory. Total drag measurements showed good agreement with the theory at low angles of attack when the effects of surface friction were included. At the higher angles of attack, both lift coefficient and drag coefficient were found to be slightly below the values predicted by the two-dimensional theory.

NACA RM L51J10

INVESTIGATION BY THE TRANSONIC-BUMP METHOD OF A 35° SWEPTBACK SEMISPAN MODEL EQUIPPED WITH A FLAP OPERATED BY A SERIES OF SERVOVANES LOCATED AHEAD OF AND GEARED TO THE FLAP. William H. Phillips and Robert F. Thompson. December 1951. 39p. diagrs., photo. (NACA RM L51J10)

Lift, drag, pitching-moment, rolling-moment, and yawing-moment data in the Mach number range from 0.6 to 1.0 obtained from wind-tunnel tests of a low-aspect-ratio sweptback airfoil model with a servovane control are presented. The control utilizes the drag force and spoiler action of a set of vanes to deflect a flap-type control. Comparison of lift increment and center-of-pressure location is made with previously published data from tests of a conventional flap-type control.

NACA RM L51J30

SUMMARY OF FLUTTER EXPERIENCES AS A GUIDE TO THE PRELIMINARY DESIGN OF LIFTING SURFACES ON MISSILES. Dennis J. Martin. November 1951. 16p. diagrs. (NACA RM L51J30)

This report presents a limited review of some experiences in flight testing of missiles and of wing flutter investigations that may be of interest in missile design. Several types of flutter which may be of concern in missile studies are briefly described. Crude criteria are presented for two of the most common types of flutter to permit a rapid estimate to be made of the probability of the occurrence of flutter. Many of the details of the flutter picture have been omitted, and only the broader elements have been retained so as to give the designer an overall view of the subject.

NACA RM L52D01

A STUDY OF THE FLOW OVER A 45° SWEPTBACK WING-FUSELAGE COMBINATION AT TRANSONIC MACH NUMBERS. Richard T. Whitcomb and Thomas C. Kelly. June 1952. 60p. diagrs., photos. (NACA RM L52D01)

Pressure distributions, tuft patterns, and schlieren surveys have been obtained for a 45° sweptback wing-fuselage combination in the Langley 8-foot transonic tunnel at transonic Mach numbers to 1.11 and angles of attack to 20°. The results provide an indication at transonic Mach numbers of the nature of the formation of shock waves on the wing and fuselage, wing-fuselage interference, and the development of separation and the separation vortex.

NACA RM L52J21a

INVESTIGATIONS AT SUPERSONIC SPEEDS OF THE BASE PRESSURE ON BODIES OF REVOLUTION WITH AND WITHOUT SWEPTBACK STABILIZING FINS. Eugene S. Love and Robert M. O'Donnell. December 1952. 66p. diagrs., photos. (NACA RM L52J21a)

Results are presented from an investigation at Mach numbers of 1.62, 1.93, and 2.41 of the variation with Reynolds number of the base pressure on bodies of revolution at zero lift, with and without sweptback stabilizing fins. Included are the effects of varying nose and base shapes and cutoff length, the effects of the presence of sting supports of varying diameter, and the effects of disturbances entering the wake. The overall Reynolds number range was approximately from 1×10^6 to 10×10^6.

NACA RM L52J23a

INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS OF THE NACA RM-10 MISSILE (WITH FINS) AT A MACH NUMBER OF 1.62 IN THE LANGLEY 9-INCH SUPERSONIC TUNNEL. Donald E. Coletti. December 1952. 21p. diagrs. (NACA RM L52J23a)

An investigation was made of a 0.050-scale model of the RM-10 missile at a Mach number of 1.62 and a Reynolds number of 2.66×10^6. Measurements were made of lift, drag, and pitching moment over an angle-of-attack range of $\pm 5°$. The effects of the ratio of sting-shield diameter to base diameter were also investigated. Comparisons are made with results of tests in other facilities at widely different Reynolds numbers.

NACA RM L52K06

PRESSURE DISTRIBUTION AND PRESSURE DRAG FOR A HEMISPHERICAL NOSE AT MACH NUMBERS 2.05, 2.54, AND 3.04. Leo T. Chauvin. December 1952. 14p. diagrs., photos. (NACA RM L52K06)

An experimental investigation of the pressure distributions on a hemispherical nose 3.98 inches in diameter, mounted on a cylindrical support, has been made at Mach numbers of 2.05, 2.54, and 3.04 and for Reynolds numbers of 4.44×10^6, 4.57×10^6, and 4.16×10^6, respectively. The Reynolds number was based on body diameter and free-stream conditions. Pressure-drag coefficients were calculated and good agreement was obtained between these tests and other investigations.

NACA RM L53E04

AILERON AND ELEVATOR HINGE MOMENTS OF THE BELL X-1 AIRPLANE MEASURED IN TRANSONIC FLIGHT. Hubert M. Drake and John B. McKay. June 1953. 27p. diagrs. (NACA RM L53E04)

Hinge moments have been measured on the aileron and elevator of the Bell X-1 airplane having the 10-percent-thick wing and 8-percent-thick tail. The aileron measurements were made by means of strain gages and pressure distributions while the elevator measurements were made by means of the wheel-force strain gages. The elevator hinge-moment characteristics were determined to a Mach number of 1.18 and the aileron hinge moments to a Mach number of 1.13.

NACA RM L53F08

FLIGHT MEASUREMENTS OF LIFT AND DRAG FOR THE BELL X-1 RESEARCH AIRPLANE HAVING A 10-PERCENT-THICK WING. Edwin J. Saltzman. September 1953. 37p. diagrs., tab. (NACA RM L53F08)

Lift and drag results have been obtained from power-off flight tests of the Bell X-1 (10-percent-thick wing) airplane for Mach numbers 0.68 to 1.01. Comparisons of drag are made with 8-percent-thick-wing flight tests and 10-percent-thick-wing wind-tunnel results.

NACA RM L53I09a

LOW-SPEED WIND-TUNNEL INVESTIGATION OF A JET CONTROL ON A 35° SWEPT WING. John G. Lowry and Thomas R. Turner. October 1953. 9p. diagrs. (NACA RM L53I09a)

A low-speed wind-tunnel investigation was made of a jet control that obtains its effectiveness from both the jet reaction and from the change in circulation around the wing due to the jet's acting as a spoiler. The jet control was investigated as an aileron on a 35° sweptback wing of aspect ratio 4.76. The investigation was of exploratory nature and was limited to the case where the jet was supplied with air at stagnation pressure. The results indicated that such a jet could be used as an emergency control.

NACA RM L53J01a

WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF STEADY ROLLING ON THE AERODYNAMIC LOADING CHARACTERISTICS OF A 45° SWEPTBACK WING AT HIGH SUBSONIC SPEEDS. James W. Wiggins and Richard E. Kuhn. November 1953. 22p. diagrs., photos. (NACA RM L53J01a)

The aerodynamic loading characteristics of a 45° sweptback wing of aspect ratio 4 in combination with a fuselage during steady roll are presented. The tests covered Mach numbers of 0.70, 0.85, and 0.91, and angles of attack up to 13°. The effects of fences at a Mach number of 0.85 and a comparison of measured and calculated load distribution are included.

NACA RM L53J09a

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF THE EFFECT OF VARYING THE RATIO OF BODY DIAMETER TO WING SPAN FROM 0.1 TO 0.8 ON THE AERODYNAMIC CHARACTERISTICS IN PITCH OF A 45° SWEPTBACK-WING—BODY COMBINATION. Harold S. Johnson. November 1953. 32p. diagrs., photo., tab. (NACA RM L53J09a)

Low-speed lift, drag, and pitching-moment data were obtained for a family of bodies and wing-body combinations to determine the effect of varying the ratio of body diameter to wing span from 0.1 to 0.8. The bodies had ogival noses and cylindrical afterbodies. The untapered 6-percent-thick wings had aspect ratios of 3 and 45° of sweepback. The lift data of the bodies alone and the wing-body combinations are compared with several existing theories.

NACA RM L53J19

AN EXPERIMENTAL AND THEORETICAL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE EFFECTS OF HORIZONTAL-TAIL HEIGHT ON THE AERODYNAMIC CHARACTERISTICS IN SIDESLIP OF AN UNSWEPT, UNTAPERED TAIL ASSEMBLY. Harleth G. Wiley and Donald R. Riley. December 1953. 71p. diagrs., tab. (NACA RM L53J19)

This paper presents the effects at high subsonic speeds of horizontal-tail height on the aerodynamic characteristics in sideslip at 0° angle of attack of an unswept, untapered empennage. Configurations investigated included the fuselage alone, fuselage plus vertical tail, fuselage plus horizontal tail, and the fuselage plus vertical tail with the horizontal tail located at 0, 26, 59, and 100 percent vertical-surface span. Tests were made at 0° angle of attack through a sideslip range of -2° to 20° over a Mach number range of 0.50 to 0.94.

NACA RM L53J29

WIND-TUNNEL INVESTIGATION AT HIGH AND LOW SUBSONIC MACH NUMBERS OF TWO UNSWEPT WINGS HAVING NACA 2-006 AND NACA 65A006 AIRFOIL SECTIONS. Stanley F. Racisz. December 1953. 40p. diagrs., photo., tab. (NACA RM L53J29)

An investigation has been made of two unswept wings with aspect ratios of 4 and taper ratios of 0.2. One wing had airfoil sections designed for high maximum lift at low speeds (NACA 2-006), and the other wing had NACA 65A006 airfoil sections. Each wing was mounted on a slender body of revolution. The lift, drag, and pitching-moment characteristics were determined at Reynolds numbers from 1×10^6 to 7.5×10^6 for Mach numbers below 0.2 for the wings with and without split flaps and for the wings with and without leading-edge roughness. The characteristics of the plain wings were also determined for several values of Reynolds number at Mach numbers up to about 0.92. Gains obtainable by the use of the NACA 2-006 airfoil section are evident for Mach numbers up to 0.65 from the comparisons of the results for the two wings.

NACA RM L53L08a

EXPERIMENTAL CONVECTIVE HEAT TRANSFER TO A 4-INCH AND 6-INCH HEMISPHERE AT MACH NUMBERS FROM 1.62 TO 3.04. Leo T. Chauvin and Joseph P. Maloney. February 1954. 18p. diagrs., photos. (NACA RM L53L08a)

Equilibrium temperatures and heat-transfer coefficients for a hemispherical nose have been measured for Mach numbers from 1.62 to 3.04. Heat transfer to the surface of the hemisphere was presented as Stanton number against Reynolds number for various surface heating conditions. Heat transfer at the stagnation point has been measured and correlated with theory. Transition from a laminar to a turbulent boundary layer was obtained at Reynolds numbers of approximately 1×10^6 corresponding to a region on the body located between 45° and 60° from the stagnation point.

NACA RM L53L15

INVESTIGATION OF A PULSE-JET-POWERED HELICOPTER ROTOR ON THE LANGLEY HELICOPTER TEST TOWER. Edward J. Radin and Paul J. Carpenter. February 1954. 23p. diagrs., photos. (NACA RM L53L15)

A helicopter rotor powered by tip-located pulse-jet engines has been investigated on the Langley helicopter test tower to determine its basic hovering characteristics as well as the power-off drag and propulsive characteristics of the engines. The noise intensity in the vicinity of the pulse-jet engines was also determined.

CURRENT NACA REPORTS

NACA RM E55B11

FULL-SCALE PERFORMANCE STUDY OF A PROTOTYPE CRASH-FIRE PROTECTION SYSTEM FOR RECIPROCATING-ENGINE-POWERED AIRPLANES. Dugald O. Black and Jacob C. Moser. November 1955. 36p. diagrs., photos. (NACA RM E55B11)

An airplane was experimentally crashed to study the performance of a prototype crash-fire inerting system for reciprocating-engine-powered airplanes. The results of previous experimental crashes indicate that the crash conditions imposed almost always result in fire. The inerting system was therefore exposed to conditions that would adequately test its ability to inert and de-energize the various ignition sources known to cause crash fires. The fact that fire did not occur during this crash indicated that the crash-fire inerting system functioned satisfactorily as a complete unit. The prototype inerting system functioned with a rapidity equal to or greater than that of the experimental system used in the NACA crash-fire studies.

NACA RM E55H11

A SURVEY OF UNCLASSIFIED AXIAL-FLOW-COMPRESSOR LITERATURE. Howard Z. Herzig and Arthur G. Hansen. November 1955. i, 88p. (NACA RM E55H11)

A survey of unclassified axial-flow-compressor literature is presented in the form of brief reviews of the methods, results, and conclusions of selected reports. The reports are organized into several main categories with subdivisions, and frequent references are made within the individual reviews to pertinent material elsewhere in the survey.

NACA RM E55I27a

AVERAGE BOND ENERGIES BETWEEN BORON AND ELEMENTS OF THE FOURTH, FIFTH, SIXTH, AND SEVENTH GROUPS OF THE PERIODIC TABLE. Aubrey P. Altshuller. November 1955. 7p. tab. (NACA RM E55I27a)

The average bond energies $\bar{D}_{gm}(B\text{-}Z)$ for boron-containing molecules have been calculated by the Pauling geometric-mean equation. These calculated bond energies are compared with the average bond energies $\bar{D}_{exp}(B\text{-}Z)$ obtained from experimental data. The higher values of $\bar{D}_{exp}(B\text{-}Z)$ in comparison with $\bar{D}_{gm}(B\text{-}Z)$ when Z is an element in the fifth, sixth, or seventh periodic group may be attributed to resonance stabilization or double-bond character.

NACA TM 1384

METALLOGRAPHY OF ALUMINUM AND ITS ALLOYS. USE OF ELECTROLYTIC POLISHING. (Métallographie de l'aluminium et de ses alliages. Emploi du polissage électrolytique). P. A. Jacquet. November 1955. ii, 80p. diagrs., photos., tabs. (NACA TM 1384. Trans. from Office National d'Études et de Recherches Aéronautiques, Pub.51, 1952)

Recent methods are described for electropolishing aluminum and aluminum alloys. Numerous references are included of electrolytic micrographic investigations carried out during the period 1948 to 1952. A detailed description of a commercial electrolytic polishing unit, suitable for micrographic examination of aluminum and its alloys, is included.

NACA TN 3413

INVESTIGATION OF THE USE OF A RUBBER ANALOG IN THE STUDY OF STRESS DISTRIBUTION IN RIVETED AND CEMENTED JOINTS. Louis R. Demarkles, Massachusetts Institute of Technology. November 1955. 97p. diagrs., tabs. (NACA TN 3413)

Results are presented of an investigation made to study the stress distribution within cemented and riveted joints by use of an analogous joint constructed of a highly flexible material. Displacement measurements obtained from foam-rubber analogs, and rational though not rigorously sound formulas for shear stress distribution in joints, are given.

NACA TN 3469

SUMMARY OF RESULTS OBTAINED BY TRANSONIC-BUMP METHOD ON EFFECTS OF PLAN FORM AND THICKNESS ON LIFT AND DRAG CHARACTERISTICS OF WINGS AT TRANSONIC SPEEDS. Edward C. Polhamus. November 1955. 33p. diagrs., tab. (NACA TN 3469. Supersedes RM L51H30)

This paper presents a summary of the effects of plan form and thickness on the lift and drag characteristics of wings at transonic speeds and comparisons with subsonic, transonic, and supersonic theories. The data considered in this summary were obtained during a transonic research program conducted in the Langley high-speed 7- by 10-foot tunnel by the transonic-bump method. The Reynolds numbers of the tests were generally less than 1×10^6.

NACA TN 3492

DETERMINATION OF INFLOW DISTRIBUTIONS FROM EXPERIMENTAL AERODYNAMIC LOADING AND BLADE-MOTION DATA ON A MODEL HELICOPTER ROTOR IN HOVERING AND FORWARD FLIGHT. Gaetano Falabella, Jr., and John R. Meyer, Jr., Massachusetts Institute of Technology. November 1955. 184p. diagrs., photos., tab. (NACA TN 3492)

Inflow distributions, azimuth and spanwise, were determined analytically from measured pressure distributions and blade-motion data on a model helicopter rotor blade under hovering and simulated forward-flight conditions. Pressures and corresponding blade flapping were recorded for various rotor conditions at tip-speed ratios of 0.10 to 1.00. Supplementary information concerning reverse-flow effects on offset-blade motion, measured forces and moments on a typical offset model rotor, and additional recorded pressure data are also included.

NACA TN 3524

THE EFFECT OF REYNOLDS NUMBER ON THE STALLING CHARACTERISTICS AND PRESSURE DISTRIBUTIONS OF FOUR MODERATELY THIN AIRFOIL SECTIONS. George B. McCullough. November 1955. 24p. diagrs., tabs. (NACA TN 3524)

Low-speed measurements of the lift, drag, pitching moment, and pressure distribution of the NACA 0008, 0007.5, 0007, and 0006 airfoil sections are presented for Reynolds numbers from 1.5 to 6 million. It is shown that the flow over these sections underwent a change at some value of the lift coefficient which depended on the airfoil thickness ratio and Reynolds number. The effect of the flow change on maximum lift was small.

NACA TN 3525

VORTEX INTERFERENCE ON SLENDER AIRPLANES. Alvin H. Sacks. November 1955. 19p. diagr. (NACA TN 3525)

Formulas are developed for the forces and moments due to vortex interference on a slender wing-body-tail combination of general cross section performing quasi-stationary maneuvers. It is found that in steady straight flight the interference lift depends only on the impulse of each shed vortex and its image vortex in a transformed circle plane, this quantity to be determined at the wing trailing edge and at the base of the configuration.

NACA TN 3526

FLIGHT CALIBRATION OF FOUR AIRSPEED SYSTEMS ON A SWEPT-WING AIRPLANE AT MACH NUMBERS UP TO 1.04 BY THE NACA RADAR-PHOTOTHEODOLITE METHOD. Jim Rogers Thompson, Richard S. Bray, and George E. Cooper. November 1955. 41p. diagrs., photos., tab. (NACA TN 3526. Supersedes RM A50H24)

The characteristics of four different airspeed systems installed in a swept-wing airplane have been investigated in flight up to 1.04 Mach number by the NACA radar-phototheodolite method of airspeed calibration. The variations of static-pressure defect per unit indicated impact pressure with Mach number and a limited amount of information on the effect of airplane normal-force coefficient are presented for each system. The results are compared with available theory and wind-tunnel tests of the isolated heads.

NACA TN 3547

AERODYNAMIC CHARACTERISTICS OF A SMALL-SCALE SHROUDED PROPELLER AT ANGLES OF ATTACK FROM 0° TO 90°. Lysle P. Parlett. November 1955. 12p. diagrs. (NACA TN 3547)

Tests have been performed to determine the effects of airspeed and angle of attack on the lift, drag, and pitching moment of a shrouded-propeller model, having a shroud length of about two-thirds of the propeller diameter, over an angle-of-attack range from 0° to 90°. Tests were made of the complete model with the propeller operating and also of the shroud alone with the propeller removed. The effect of inlet-lip cross-sectional radius on the static-thrust characteristics was also studied.

NACA TN 3548

FLIGHT INVESTIGATION AT MACH NUMBERS FROM 0.6 TO 1.7 TO DETERMINE DRAG AND BASE PRESSURES ON A BLUNT-TRAILING-EDGE AIRFOIL AND DRAG OF DIAMOND AND CIRCULAR-ARC AIRFOILS AT ZERO LIFT. John D. Morrow and Ellis Katz. November 1955. 19p. diagrs., photos. (NACA TN 3548. Supersedes RM L50E19a)

Results of an exploratory free-flight investigation at zero lift of several rocket-powered drag-research models having rectangular 6-percent-thick wings are presented for a Mach number range of 0.6 to 1.7. Wings having diamond, circular-arc, and blunt-trailing-edge airfoil sections were tested. Pressures over the base of the blunt-trailing-edge airfoil were measured. The drags of all the models were measured and are compared with theory in this paper.

NACA TN 3569

COMPRESSIBLE LAMINAR BOUNDARY LAYER AND HEAT TRANSFER FOR UNSTEADY MOTIONS OF A FLAT PLATE. Simon Ostrach. November 1955. 26p. diagrs., tab. (NACA TN 3569)

The laminar compressible boundary layer and heat transfer over an isothermal semi-infinite flat plate moving with a time-dependent velocity has been analyzed. First-order deviations from the quasi-steady velocity and temperature profiles and boundary-layer characteristics have been computed. A plate oscillating about a steady velocity is considered as an example.

NACA TN 3574

ACOUSTIC ANALYSIS OF RAM-JET BUZZ. Harold Mirels. November 1955. 33p diagrs. (NACA TN 3574)

A one-dimensional analysis of ram-jet buzz is presented. It is assumed that the buzz has a linear instability origin and that the combustion chamber is of constant area. The configuration is shown to be unstable when the real part of the acoustic impedance of the inlet is greater than a term of the order of the combustion-chamber Mach number. Computations indicate that burning with a fixed planar flame front and constant heat release per unit mass increases the stable operating range.

NACA TN 3583

CHARTS OF BOUNDARY-LAYER MASS FLOW AND MOMENTUM FOR INLET PERFORMANCE ANALYSIS MACH NUMBER RANGE, 0.2 TO 5.0. Paul C. Simon and Kenneth L. Kowalski. November 1955. 32p. diagrs., tab. (NACA TN 3583)

Significant flow parameters for various fractions of a turbulent boundary layer are presented in chart form for a number of power-law velocity profiles and a range of Mach numbers up to 5.0. Estimates of auxiliary inlet mass flow or momentum may easily be made. Application of the charts to inlets of arbitrary shape and to the determination of the pressure recovery of rectangular normal-shock inlets immersed in boundary layer is described.

NACA TN 3586

IMPINGEMENT OF WATER DROPLETS ON NACA 65A004 AIRFOIL AT 0° ANGLE OF ATTACK. Rinaldo J. Brun and Dorothea E. Vogt. November 1955. 28p. diagrs. (NACA TN 3586)

The trajectories of droplets in the air flowing past an NACA 65A004 airfoil at an angle of attack of 0° were determined. The amount of water in droplet form impinging on the airfoil, the area of droplet impingement, and the rate of droplet impingement per unit area on the airfoil surface were calculated from the trajectories and presented to cover a large range of flight and atmospheric conditions. These impingement characteristics are compared briefly with those previously reported for the same airfoil at angles of attack of 4° and 8°.

National Gas Turbine Establishment (Gt. Brit.)
AN EXPERIMENTAL INTRODUCTION TO THE JET FLAP. N. A. Dimmock. July 1955. 68p. diagrs., photos., tabs. (NGTE R. 175)

Results are given of two airfoils, each having 12.5-percent-thick elliptical cross section with a narrow full-span jet slot at the trailing edge, the jet deflections being, respectively, 90° and 31.4°. The values of the force and moment coefficients and derivatives agree with those suggested by theory in a previous report. Support is given to the thrust hypothesis in that the measured thrust was greater, under appropriate conditions, than the reaction component from the deflected jet. The losses in the system are considered and some are investigated, those due to Reynolds number and jet entrainment effects being included. Influence of ground on lift and center of lift was measured and found not to be prohibitive.

TESTS OF HUMIDITY EFFECTS ON FLOW IN A WIND TUNNEL AT MACH NUMBERS BETWEEN 2.48 AND 4. R. J. Monaghan. January 1955. 33p. diagrs. (RAE Tech. Note Aero 2358)

Static and pitot pressure distributions were measured in the working section of a 5-in. by 5-in. supersonic wind tunnel at nominal Mach numbers of 2.48, 3.25, and 4, over ranges of absolute humidity at the inlet from 5×10^{-5} to 3×10^{-3}. Previous work indicates that a condensation shock would occur in the nozzle. For a stagnation pressure of 1 atmosphere and stagnation temperatures giving zero heat-transfer conditions at the walls, no humidity effects were discernible if the absolute humidity was less than 2×10^{-4} at $M = 2.48$, 3×10^{-4} at $M = 3.12$, and about 5×10^{-4} at $M = 3.8$.

TESTS ON A SWEPT-BACK WING AND BODY WITH ENDPLATES AND WING TIP TANKS IN THE COMPRESSED AIR TUNNEL. C. Salter and R. Jones. APPENDIX - COMPARISON BETWEEN THE MEASURED LIFT AND DRAG AND CALCULATED VALUES FOR THE WING WITH TIP TANKS. J. Weber. 1954. 26p. diagrs., tabs. (ARC CP 196)

Results are given of experiments to determine the effect on lift, drag and pitching moment, of wing tip tanks and of two sizes of end plates on a tapered swept wing model. The tests were undertaken primarily to extend the range of Reynolds number for checks on previous theoretical work. As regards lift and pitching moment, the effects are found to be fairly well defined. The drag characteristics are less consistent, but it seems that end plates have the effect of reducing the drag of the model over quite a large range of C_L. This does not apply in the case of the wing tip tanks.

Aeronautical Research Council (Gt. Brit.)
WIDE RANGE AMPLIFIER FOR TURBULENCE MEASUREMENTS WITH ADJUSTABLE UPPER FREQUENCY LIMIT. H. Schuh and D. Walker. 1955. 42p. diagrs. (ARC CP 198)

Requirements are discussed for an amplifier suitable for subsonic and supersonic turbulence work with hot wires. An amplifier is described which has a frequency range from 1.4 c/s to 50 kc/s, dealing with a range of thermal time lag from 0.1 m. s. to 5 m. s. An iron dust-cored inductance is used to give the required compensation for thermal lag, the circuit being a modification of Dryden's circuit. The upper frequency cutoff is adjustable in six steps from 1.5 kc/s to 50 kc/s. The output can be applied to a thermocouple meter and to an oscilloscope.

Aeronautical Research Council (Gt. Brit.)
OBSERVATIONS OF THE FLOW ROUND A TWO-DIMENSIONAL AEROFOIL OSCILLATING IN A HIGH-SPEED AIR STREAM. A. Chinneck, D. W. Holder, and C. J. Berry. 1955. 18p. diagrs., photos., tab. (ARC R & M 2931. Supersedes ARC 15, 141; FM 1779 & 0.1006)

Photographs have been taken of the flow around a 10-percent-thick RAE 104 airfoil performing pitching oscillations at low values of the frequency parameter in subsonic and supersonic airstreams. Apart from a difference of phase, the general flow pattern appeared to be similar to those observed in steady motion, the pattern for a particular instantaneous incidence of the oscillation resembling that for steady motion at a different incidence. It is suggested that, for the range of frequency parameter covered, the observed phase lag of the flow pattern corresponds to the lag in the circulation.

Aeronautical Research Council (Gt. Brit.)
THE AERODYNAMIC EFFECTS OF ASPECT RATIO ON FLUTTER OF UNSWEPT WINGS. W. G. Molyneux and E. W. Chapple. 1955. 12p. diagrs., tab. (ARC R & M 2942; 15,609. Supersedes RAE Structures 135)

A method is described for the direct measurement of the aerodynamic effects of aspect ratio on wing flutter. The method requires the use of stiff (virtually rigid) wings flexibly mounted at the root. Details are given of tests on untapered, unswept wings with freedoms in modes of linear flexure and uniform pitch. A comparison is made between measured values of the flutter characteristics and the values calculated using an aerodynamic theory for oscillating wings of finite aspect ratio, and reasonable agreement for flutter speeds and frequencies is obtained.

Royal Aircraft Establishment (Gt. Brit.)
MEASUREMENTS OF PITCHING MOMENT DERIVATIVES FOR A SERIES OF RECTANGULAR WINGS AT LOW WIND SPEEDS. P. R. Guyett and D. E. G. Poulter. June 1955. 52p. diagrs., tabs. (RAE Structures 185)

The direct aerodynamic moments for pitching oscillations have been measured on a series of rectangular wings having aspect ratios between 2 and 8 for axis positions at the wing leading edges and trailing edges. Two of the wings were also tested with single end plates which were aerodynamically effective in doubling the wing geometric aspect ratio. The measurements were made at low speeds in an open jet wind tunnel and covered the range of frequency parameter (based on wing chord) 0.13 to 0.39. The results are in general agreement with theoretical results due to Lawrence and Gerber. Similar tests were also made on a wing fitted with two end plates in an attempt to obtain results for two-dimensional flow. The results do not agree with other experimental results and two-dimensional theoretical values and indicate that wind-tunnel interference is important for this test configuration.

Royal Aircraft Establishment (Gt. Brit.)
THE EFFECTS OF TAPER ON THE SUPERVELOCITIES ON THREE-DIMENSIONAL WINGS AT ZERO INCIDENCE. K. W. Newby. June 1955. 120p. diagrs., tab. (RAE Aero 2544)

Relationships have been derived for expressing the velocities on three-dimensional tapered wings at zero incidence in terms of the velocities on untapered infinite swept wings. The theoretical investigation of the effects of taper is confined to simple wings having airfoil sections formed by cubic or parabolic arcs; some experimental evidence is given to show that the results of this investigation can probably be applied quantitatively to wings having conventional airfoil sections. The results given in this report show that plan form and thickness taper have a marked effect on the velocities near the center of a wing, but that these effects decrease with increase of sweepback. A calculation method is outlined in section 4.26 of the text for applying the results obtained for wings having parabolic arc airfoil sections, to wings having arbitrary section shapes.

WIND TUNNEL TESTS ON A 6 FT DIAMETER HELICOPTER ROTOR. T. B. Owen, R. A. Fail, and R. C. W. Eyre. May 1955. 33p. diagrs., tabs. (RAE Tech. Note Aero 2378)

Thrust, torque, and flapping angle have been measured on a 6-foot diameter rotor over a range of blade angle, shaft inclination, and tip speed ratio for comparison with the 12-foot diameter rotor previously tested in the 24-foot tunnel. In addition to tests in the 24-foot tunnel, the 6-foot diameter rotor was also tested in the No. 2 11-1/2 foot tunnel to investigate tunnel constraint. Brief investigations were made of support interference and blade twisting. There are small discrepancies both as regards tunnel corrections and as regards the comparison of the 6-foot and 12-foot diameter rotors in the unstalled operating range. Possible reasons are discussed but small unexplained discrepancies remain. Blade stalling has larger effects on the 6-foot diameter rotor but owing to the progressive nature of the phenomenon it is not possible to define any precise limits to the ranges of validity of the results on the two rotors.

Royal Aircraft Establishment (Gt. Brit.)
INVESTIGATION OF THE FATIGUE OF EXTRUDED TUBULAR BOOMS. W. A. P. Fisher and H. Yeomans. June 1955. 15p. diagrs., photos., tabs. (RAE Tech. Note Structures 162).

The presence of the unmachined extruded surface of the bore in the tubes, as used for the "Viking" and "Valetta" spar booms, has a marked adverse effect on the basic fatigue strength of the tube. The failures of the necked specimens show that the flaws at the inner surface are a source of fatigue. Scatter in the endurance of tubular spar booms is probably largely due to the chances of such flaws occurring at the side of a transverse hole. The specimens were made from aluminum alloy extruded tube DTD 364.

Marine Aircraft Experimental Establishment. (Gt. Brit.) INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS - HYDRODYNAMIC STABILITY. PART 17 - THE STABILITY AND SPRAY CHARACTERISTICS OF MODEL M. J. K. Friswell, D. M. Ridland, and A. G. Kurn. April 1955. 24p. diagrs., photos., tabs. (MAEE F/Res/253)

In this report results are presented of limited tests on the hydrodynamic characteristics of model M of the series, these tests being designed solely to provide information on the interactions of the different relevant parameters. The model has a length-to-beam ratio of 13 (the forebody being 6 beams in length and the afterbody 7 beams), no forebody warp, an afterbody to forebody keel angle of 8°, and a straight transverse step with a step depth of 0.15 beams. The tests comprised the determination of longitudinal stability limits without slipstream at $C_{\Delta_0} = 2.75$ and an investigation of spray at this loading. A short discussion of the results is also included.

CORRELATED FATIGUE DATA FOR AIRCRAFT STRUCTURAL JOINTS. R. B. Heywood. June 1955. 16p. diagrs., tab. (RAE Structures 184)

Results of fatigue tests carried out at RAE on typical aircraft wing structural joints are correlated to give an indication of general fatigue behavior. The results are plotted in the form of S - Log N curves, and these indicate that the mode of behavior cannot be attributed to any single factor, such as the type of aluminum alloy, the ultimate tensile strength, or the mean stress of the fatigue cycle. The detailed method of design undoubtedly has a predominant influence on behavior, but this quality is not revealed by a broad classification according to the proportion of load transmitted at holes.

Royal Aircraft Establishment (Gt. Brit.)
A TECHNIQUE FOR THE MEASUREMENT OF PRESSURE DISTRIBUTION ON OSCILLATING AEROFOILS, WITH RESULTS FOR A RECTANGULAR WING OF ASPECT RATIO 3.3. W. G. Molyneux and F. Ruddlesden. June 1955. 24p. diagrs., tabs. (RAE Tech. Note Structures 164)

Details are given of a strain-gage pressure transducer that has been developed for measurements of pressure distribution on oscillating airfoils in low speed wind tunnels. The transducer characteristics are shown to be well suited to oscillatory measurements, and in particular the transducer output can be measured directly on a sensitive galvanometer without the need for preamplification. As an illustration of the use of the transducer, pressure measurements have been made in the RAE 5-foot diameter open jet wind tunnel on a rectangular wing of aspect ratio 3.3 oscillating in modes of pitch and roll. Values for the aerodynamic derivatives have been obtained from the integrated pressure distributions, and are compared with those derived from overall force measurements and with theoretical values. The measured values are in close agreement but there are some discrepancies with theory that are thought to be due to a wind-tunnel interference effect.

Royal Aircraft Establishment (Gt. Brit.)
THE INFLUENCE OF PRE-LOADING ON THE FATIGUE LIFE OF AIRCRAFT COMPONENTS AND STRUCTURES. R. B. Heywood. June 1955. 27p. diagrs., photos., tabs. (RAE Structures 182)

Tests on aircraft components and structures are described which show that preloading can have a marked influence on fatigue behavior. Tensile preloading may increase the life - in one instance a hundredfold improvement was obtained - and compressive preloading may reduce the life. The effect is attributed to residual stresses and to load redistributions induced by preloading.

AN ABSORPTIOMETRIC METHOD FOR THE DETERMINATION OF CHROMIUM IN METHACRYLATO-CHROMIUM TREATED GLASS FABRIC. E. J. McLauchlan. August 1955. 4p. diagr. (MOS AID Chem. 6)

An absorptiometric method for the determination of chromium in methacrylato-chromium treated glass fabric is described. A wet-oxidation attack is utilized to remove the chromium from the glass fibers and to oxidize the tervalent chromium to sexavalent chromium for subsequent absorptiometric determination as the diphenylcarbazide complex.

OPTIMUM DESIGNS FOR REINFORCED CIRCULAR HOLES. E. H. Mansfield. June 1955. 26p. diagrs. (RAE Structures 183)

The design of reinforced circular holes in an infinite sheet is considered theoretically. The stress system in the main body of the sheet is assumed to be one in which the principal stresses are in the ratio 1:-1 (that is, shear), 1:0 (that is, tension), 1:1 or 1:1/2. The reinforcement may vary round the hole and families of such reinforcements with constant total weight are considered; the peak stresses in the sheet are evaluated so that optimum weight-strength designs are determined.

STATIC ELECTRICITY IN AIRCRAFT FUEL TANKS. F. L. Holmes and D. T. Sharwood. May 1955. 10p. diagrs., tab. (RAE Tech. Note EL.82; Tech. Note Mech. Eng. 201)

Tests were made to measure the static field strength generated in aircraft fuel tanks by foaming of the fuel. A type of apparatus for measuring static field strength is described with details of its application to these tests. The results show that the field strength is less than 1 volt per centimeter which is many times less than that required for flashover and the ignition of a fuel vapor/air mixture.

FLOW NEAR A HEATED SOLID BODY IN A STANDING ACOUSTIC WAVE. P. N. Kubanskii. October 1955. 11p. diagrs. (Trans. of Zhurnal Tekhnicheskoi Fiziki, v. 22, no. 4, April 1952, p. 585-592)

Results of experiments carried out in standing waves generated by vibrations of finite amplitude are presented. Two types of waves are considered: (1) forced standing waves, formed when the frequency of outside vibrations does not correspond with the natural frequency of vibration of the radiating system, and (2) standing waves which form as the result of coincidence of frequency of outside vibration with natural frequency of vibration of the radiating system. Optical methods are used in the examination of the flow and the presence of higher harmonics in the standing acoustical wave is observed. The deformation of the waves is also studied.

SOFT ROT. DESTRUCTION OF WOOD THROUGH COMMON FUNGI. (Moderfaule. Die Zersetzung von Holz durch niedere Pilze). W. P. K. Findlay and J. G. Savory. October 1955. 12p. photos., tab. (Trans. from Holz als Roh- und Werkstoff, v.12, no.8, August 1954, p.293-296).

If wood is exposed to humid weather for some length of time, a softening of the surface takes place which is due to a fungus attack. This phenomenon is of minor significance except in the case of cooling towers and similar industrial water-cooling plants. Soft rot, as this fungus is generally called, was produced according to a method by Abrams. The fungi causing soft rot are reviewed and preservatives for protection of wood are discussed, but further investigations are required in order to indicate effective methods of protection of wood from soft rot.

N-39717*

EFFECT OF ACOUSTICAL VIBRATIONS OF FINITE AMPLITUDE ON THE BOUNDARY LAYER. P. N. Kubanskii. October 1955. 11p. diagrs. (Trans. of Zhurnal Tekhnicheskoi Fiziki, v.22, no.4, April 1952, p.593-601)

It is concluded that acoustical standing waves of finite amplitude can produce currents near the wall of a solid body, even when the body is located in a stream. A considerable intensity of acoustical vibration is necessary in order to produce acoustical flow near the walls of a solid body in a stream. The acoustical streams produced near the walls of solid bodies exert an influence on the boundary layer which surrounds the body. There is a possibility of using acoustical vibrations to control phenomena which occur in the boundary layer. Such phenomena could be directed toward the desired side of a physical body, depending upon the condition of the boundary layer.

NACA RM A50J26a

AERODYNAMIC CHARACTERISTICS INCLUDING PRESSURE DISTRIBUTIONS OF A FUSELAGE AND THREE COMBINATIONS OF THE FUSELAGE WITH SWEPT-BACK WINGS AT HIGH SUBSONIC SPEEDS. Fred B. Sutton and Andrew Martin. February 6, 1951. 117p. diagrs., photos., tabs. (NACA RM A50J26a) (Declassified from Confidential, 10/14/55)

As part of an NACA transonic research program, three sweptback wings with a fuselage were investigated over a Mach number range from 0.40 to 0.94. These model wings had NACA 65A006 sections parallel to the plane of symmetry. One of the model wings was swept back 35° and had an aspect ratio of 6; the other two were swept back 45° and had aspect ratios of 4 and 6. Force and pitching-moment data, tabulated pressure measurements, downwash and dynamic-pressure characteristics, and tuft studies are presented. The approximate effects of wing elasticity on lift and moment data are also shown.

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM CONFIDENTIAL 11/14/55, AND ARE UNAVAILABLE:

THE FOLLOWING REPORTS HAVE BEEN DECLASSIFIED FROM CONFIDENTIAL, 11/14/55

NACA RM A7K28

HIGH-SPEED STABILITY AND CONTROL CHARACTERISTICS OF A FIGHTER AIRPLANE MODEL WITH A SWEPT-BACK WING AND TAIL. Charles P. Morrill, Jr., and Lee E. Boddy. April 14, 1948. 47p. diagrs., photos. (NACA RM A7K28)

Wind-tunnel tests were made at high subsonic Mach numbers of a model of a pursuit airplane with a 35° sweptback wing and tail. Data are included in the report which show the basic characteristics of the model; the control and hinge-moment characteristics of the horizontal tail, elevator, and aileron; the effect of a wing leading-edge slat; and the effect of a fuselage-side dive brake.

NACA RM A9K02

INVESTIGATION OF DOWNWASH AND WAKE CHARACTERISTICS AT A MACH NUMBER OF 1.53. III - SWEPT WINGS. Edward W. Perkins and Thomas N. Canning. February 23, 1950. 41p. diagrs., tab. (NACA RM A9K02)

The results of an experimental investigation of the downwash and wake characteristics behind two highly swept wings in a supersonic stream are presented. The leading-edge sweep angles of the two wings were 63° and $63^{\circ}45'$, the aspect ratios were 3.50 and 1.66, and the corresponding taper ratios were 0.25 and 1.00. The tests were made at a Mach number of 1.53 and Reynolds numbers of 1.4 million and 2.6 million, respectively. A comparison between experimental and theoretical values of the rate of change of downwash angle with angle of attack at zero lift is made.

NACA RM A52K12

TECHNIQUES FOR DETERMINING THRUST IN FLIGHT FOR AIRPLANES EQUIPPED WITH AFTERBURNERS. L. Stewart Rolls, C. Dewey Havill, and George R. Holden. January 1953. 27p. diagrs., photos. (NACA RM A52K12)

An experimental technique has been developed which enables a determination of the net thrust for an afterburner-equipped airplane in flight. Measurements from a swinging pitot-static pressure and total temperature probe are used to determine the gross thrust, total air-flow rate, and net thrust. Details are also presented for an air-cooled fixed-pressure probe for the determination of basic engine thrust.

NACA RM A52K13

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF AN AIRPLANE MODEL WITH AN ASPECT RATIO 4 TRIANGULAR WING AND AN ALL-MOVABLE HORIZONTAL TAIL - HIGH-LIFT DEVICES AND LATERAL CONTROLS. Ralph W. Franks. February 1953. 45p. diagrs., photo., 2 tabs. (NACA RM A52K13)

Tests have been made of a model consisting of a triangular wing in combination with a fuselage of fineness ratio 12.5; a thin, triangular, vertical tail with a constant-chord rudder; and a thin, unswept, all-movable horizontal tail. The wing had an NACA 0005 modified section and was equipped with slotted inboard and plain outboard flaps. Tests were made with the wing-fuselage-vertical-tail configuration in addition to the tests of the complete model. The results of tests of lateral and directional controls, the inboard flaps as a high-lift device, and the outboard flaps as a high-lift device are presented. The Reynolds number, based on the wing mean aerodynamic chord, was approximately 10.9 million and the Mach number was about 0.13.

NACA RM A53C19

EXPERIMENTAL INVESTIGATION OF THE EFFECTS OF PLAN-FORM TAPER ON THE AERODYNAMIC CHARACTERISTICS OF SYMMETRICAL UNSWEPT WINGS OF VARYING ASPECT RATIO. Edwin C. Allen. May 1953. 53p. diagrs., photos., tab. (NACA RM A53C19)

This report presents results of tests of a series of symmetrical, unswept, 8-percent-thick wings of varying aspect ratio and taper ratio. The wings were tested in combination with four different bodies of revolution over a Mach number range from 0.40 to 0.94 with a corresponding Reynolds number range from 2.58 million to 5.90 million. The lift, drag, and pitching-moment data are presented for wings of aspect ratios 2, 3, and 4 and for taper ratios of 0.20 to 1.00.

NACA RM E51K15

COMPARISON OF LOCKED-ROTOR AND WINDMILLING DRAG CHARACTERISTICS OF AN AXIAL-FLOW-COMPRESSOR TYPE TURBOJET ENGINE. K. R. Vincent, S. C. Huntley, and H. D. Wilsted. January 1952. 10p. diagrs. (NACA RM E51K15)

The internal drag of an axial-flow turbojet engine with the rotor locked in place to prevent windmilling and with the engine windmilling was obtained over a range of simulated Mach numbers. The corrected internal drag of the engine with the locked rotor was 210 pounds or only 46 percent of the windmilling drag at a flight Mach number of 0.8.

NACA RM E53K06

ANALYTICAL STUDY OF LOSSES AT OFF-DESIGN CONDITIONS FOR A FIXED-GEOMETRY TURBINE. Warner L. Stewart and David G. Evans. February 1954. 48p. diagrs., tab. (NACA RM E53K06)

An analytical investigation was made to determine the off-design loss characteristics of a fixed-geometry turbine of which the experimental performance was known. The method of analysis utilized an effective loss parameter and assumed that the velocity normal to the blade entrance angle was lost as a total-pressure loss. The method also assumed constant tangential component of velocity between the station just upstream and just downstream of the stator and rotor trailing edge. Good correlation between the analytically and experimentally obtained performance was found over the entire map until limiting loading was approached. The large decrease in efficiency at low-speed high pressure ratios and at high-speed low pressure ratios was found in the analysis to be almost entirely due to the rotor incidence and turbine exit whirl losses. From the results of the investigation it was concluded that for turbines designed to operate efficiently at more than one point, the design must compromise rotor incidence angle and exit whirl losses.

NACA RM L8K12a

HINGE-MOMENT MEASUREMENTS OF A WING WITH LEADING-EDGE AND TRAILING-EDGE FLAPS AT A MACH NUMBER OF 1.93. William B. Boatright and Robert W. Rainey. January 14, 1949. 12p. diagrs., tab. (NACA RM L8K12a)

Hinge-moment data for a wing with leading-edge and trailing-edge flaps of wedge section were obtained in the Langley 9-inch supersonic tunnel at a Mach number of 1.93 and a Reynolds number of 1.31×10^6. Curves of hinge moment against angle of attack and against flap deflection are shown, and the results are compared with theory. The possibility of a linkage system to reduce control forces is discussed.

NACA RM L8K17a

CONTROL EFFECTIVENESS AND HINGE-MOMENT MEASUREMENTS AT A MACH NUMBER OF 1.9 OF A NOSE FLAP AND TRAILING-EDGE FLAP ON A HIGHLY TAPERED LOW-ASPECT-RATIO WING. D. William Conner and Meade H. Mitchell, Jr. January 10, 1949. 26p. diagrs., photo. (NACA RM L8K17a)

Nose flaps and trailing-edge flaps were tested on a low-aspect-ratio, highly tapered, half-span wing model in the Langley 9- by 12-inch supersonic blowdown tunnel at a Mach number of 1.9 and a Reynolds number of 3,000,000. Lift, drag, pitching- and rolling-moment data for the wing and hinge-moment data for the flaps were obtained. All tests were made in the presence of a fuselage.

NACA RM L8K24a

EXPERIMENTAL AND CALCULATED HINGE MOMENTS OF TWO AILERONS ON A 42.7° SWEPTBACK WING AT A MACH NUMBER OF 1.9. James C. Sivells and Kennith L. Goin. January 19, 1949. 23p. diagrs., photos., tabs. (NACA RM L8K24a)

A 42.7° sweptback wing was tested with two types of ailerons in the Langley 9- by 12-inch supersonic blowdown tunnel at a Mach number of 1.9 and a Reynolds number of 2.2×10^6. The wing had an aspect ratio of 4, a taper ratio of 0.5, and an 8-percent-thick biconvex airfoil section. The contour of one aileron was formed by the basic airfoil contour, and the other aileron had flat sides and a trailing-edge thickness of one-half the hinge-line thickness.

NACA RM L9K01a

ROCKET-POWERED FLIGHT TEST OF A ROLL-STABILIZED SUPERSONIC MISSILE CONFIGURATION. Robert A. Gardiner and Jacob Zarovsky. January 12, 1950. 32p. diagrs., photos., tab. (NACA RM L9K01a)

A missile research model incorporating wing-tip ailerons and a gyro-actuated automatic roll control was flight tested at supersonic speed. The aerodynamic rolling derivatives for zero-lift flight were determined from the flight record. It was concluded that the method used in the preflight system analysis is valid and that the gyro-actuated tip-aileron control system provided a satisfactory means of obtaining roll stabilization in zero-lift supersonic flight.

NACA RM L9K09

AERODYNAMIC INVESTIGATION OF A PARABOLIC BODY OF REVOLUTION AT MACH NUMBER OF 1.92 AND SOME EFFECTS OF AN ANNULAR JET EXHAUSTING FROM THE BASE. Eugene S. Love. February 8, 1950. 75p. diagrs., photos., tab. (NACA RM L9K09)

An aerodynamic investigation of a slender pointed parabolic body of revolution was conducted at a Mach number of 1.92 with and without the effects of an annular supersonic jet exhausting from the base. Measurements without the jet in operation were made of lift, drag, pitching moment, base pressures, and radial and axial pressures. With the jet in operation, pressure measurements were made over the rear of the body with the primary variables being angle of attack, ratio of jet velocity to stream velocity, and ratio of pressure at jet exit to stream pressure.

NACA RM L50K06

HORIZONTAL-TAIL EFFECTIVENESS AND DOWNWASH SURVEYS FOR TWO 47.7° SWEPTBACK WING-FUSELAGE COMBINATIONS WITH ASPECT RATIOS OF 5.1 AND 6.0 AT A REYNOLDS NUMBER OF 6.0×10^6. Reino J. Salmi. January 12, 1951. 65p. diagrs., photos., 2 tabs. (NACA RM L50K06)

Results of wind-tunnel tests on two 47.7° sweptback wing-fuselage combinations of aspect ratios 5.1 and 6.0 to determine the effects of the vertical location of a horizontal sweptback tail on tail effectiveness and the static longitudinal stability were presented. The tests were made at a Reynolds number of about 6.0×10^6 (Mach number of 0.14) for various combinations of leading-edge and trailing-edge flaps. The results of airstream surveys in the region of the tail are also presented.

NACA RM L50K29

LOW-SPEED LONGITUDINAL AND WAKE AIR-FLOW CHARACTERISTICS AT A REYNOLDS NUMBER OF 6.0 x 10^6 OF A 52° SWEPTBACK WING EQUIPPED WITH VARIOUS SPANS OF LEADING-EDGE AND TRAILING-EDGE FLAPS, A FUSELAGE, AND A HORIZONTAL TAIL AT VARIOUS VERTICAL POSITIONS. Roland F. Griner and Gerald V. Foster. February 28, 1951. 66p. diagrs., photo., 3 tabs. (NACA RM L50K29)

The results are presented of an investigation conducted in the Langley 19-foot pressure tunnel at a Reynolds number of 6.0 x 10^6 to determine the effects of leading-edge-flap spans on an NACA 64-series wing swept back 52°. Several of the more satisfactory spans of leading-edge flaps were investigated with various combinations of trailing-edge flaps, fences, a fuselage, and a horizontal tail. Surveys of downwash angle, sidewash angle, and dynamic pressure ratio behind the wing at approximately the location of a horizontal tail are presented.

NACA RM L51I05

EFFECT OF FORMATION POSITION ON LOAD FACTORS OBTAINED ON F2H AIRPLANES. Carl R. Huss and Harold A. Hamer. December 1951. 15p. diagrs., 3 tabs. (NACA RM L51I05)

Plots of load factor against airplane position are presented for three combinations of four airplanes flying in formation. The plots show that the load-factor trend was to increase toward the end of the formation. Typical time histories are presented.

NACA RM L51K30

TIME HISTORIES OF MANEUVERS PERFORMED WITH AN F-86A AIRPLANE DURING SQUADRON OPERATIONS. Harold A. Hamer and Campbell Henderson. February 1952. 90p. diagrs., 3 tabs. (NACA RM L51K30)

Some preliminary results of maneuvers performed during U. S. Air Force squadron operations with an F-86A jet-fighter airplane are presented in time-history form. The maneuvers cover a speed range from the stall to 530-mile-per-hour indicated airspeed and pressure altitudes varying from sea level to approximately 25,000 feet. Variation of the maximum airplane linear and angular accelerations experienced during the investigation are also presented.

NACA RM L52K07

FREE-FLIGHT INVESTIGATION AT ZERO LIFT IN THE MACH NUMBER RANGE BETWEEN 0.7 AND 1.4 TO DETERMINE THE EFFECTIVENESS OF AN INSET TAB AS A MEANS OF AERODYNAMICALLY RELIEVING AILERON HINGE MOMENTS. William M. Bland, Jr., and Edward T. Marley. January 1953. 19p. diagrs., photos. (NACA RM L52K07)

An experimental investigation employing a technique which utilized a zero-lift rocket-propelled model in free flight has been made to determine some of the characteristics of an inset tab as an aerodynamic balance in the Mach number range between 0.7 and 1.4. The fixed, 0.09-chord, full-span, inset tab that was investigated was attached to a 0.3-chord full-span aileron on a wing of aspect ratio 3 and taper ratio 0.6 that had the quarter-chord line swept back 45° and NACA 65A006 airfoil sections parallel to the model center line. Results of this investigation show that the tab was capable of balancing (trimming) the aileron hinge moments throughout the Mach number range investigated even though the effectiveness of the tab decreased with increasing Mach number. It was shown that the aileron rolling effectiveness was decreased considerably when the tab was used to reduce the aileron hinge moments. The tab when considered as a servotab was an effective aerodynamic balance for Mach numbers less than 1.1. At no time during the investigation did the mass-balanced aileron show any evidence of buzz or flutter. It was also shown that the tab effectiveness could be estimated with reasonable accuracy from experimental data and from thin-airfoil theory.

NACA RM L52K25

INVESTIGATION OF THE EFFECT OF CHORDWISE POSITIONING AND SHAPE OF AN UNDERWING NACELLE ON THE HIGH-SPEED AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK TAPERED-IN-THICKNESS-RATIO WING OF ASPECT RATIO 6. H. Norman Silvers and Thomas J. King, Jr. January 1953. 50p. diagrs. (NACA RM L52K25)

An investigation at high speeds of chordwise positioning of underwing nacelles at a spanwise location of 0.46 semispan with an ogive-cylinder shape (fineness ratio = 9.34), an NACA 65A-series airfoil of revolution shape (fineness ratio = 10.68), and a modified NACA 0-series airfoil of revolution shape reversed in direction (fineness ratio = 10.04) was made on a small-size 45° sweptback tapered-in-thickness-ratio wing of aspect ratio 6.

NACA RM L53K16

AN AIR-FLOW-DIRECTION PICKUP SUITABLE FOR TELEMETERING USE ON PILOTLESS AIRCRAFT. Wallace L. Ikard. March 1954. 25p. diagrs., photos. (NACA RM L53K16)

A vane-type air-flow-direction pickup is described which is suitable for telemetering angle-of-attack and angle-of-sideslip data from rocket-propelled pilotless aircraft models. Test results which are presented show that the device performs well under high accelerations and is stable throughout a Mach number range from subsonic to above a Mach number of 2.5.

NACA RM L53K18

EXPERIMENTAL INVESTIGATION OF THE OSCILLATING FORCES AND MOMENTS ON A TWO-DIMENSIONAL WING EQUIPPED WITH AN OSCILLATING CIRCULAR-ARC SPOILER. Sherman A. Clevenson and John E. Tomassoni. January 1954. 20p. diagrs., photos. (NACA RM L53K18)

Results of a wind-tunnel investigation of the forces, moments, and phase angles on a two-dimensional wing equipped with an oscillating circular-arc spoiler are presented. Schlieren photographs are presented which show the flow over and behind the spoiler. Data for Reynolds numbers from 1.3×10^6 to 6.3×10^6, Mach numbers from 0.2 to 0.82, and reduced frequencies from 0 to 0.92 on the normal-force and pitching-moment coefficients and their respective phase angles referred to spoiler position are indicated.

NACA RM L53K30

PRELIMINARY INVESTIGATION OF THE FLOW IN AN ANNULAR-DIFFUSER—TAILPIPE COMBINATION WITH AN ABRUPT AREA EXPANSION AND SUCTION, INJECTION, AND VORTEX-GENERATOR FLOW CONTROLS. John R. Henry and Stafford W. Wilbur. February 1954. 27p. diagrs. (NACA RM L53K30)

The performance of an annular-diffuser—tailpipe combination with an abrupt area expansion was investigated with and without flow controls in the form of suction, injection, and vortex generators. The diffuser had a 21-inch-diameter straight outer wall, an area ratio of 1.9 to 1, and fully developed pipe flow at the inlet. Inlet Mach number was varied between 0.18 and 0.43. The ratio of the auxiliary air flow to the flow of the main stream was varied from 0 to approximately 4 percent. (Both suction and injection flow controls were effective in producing improved diffuser performance.)

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1195

FORMULAS FOR THE ELASTIC CONSTANTS OF PLATES WITH INTEGRAL WAFFLE-LIKE STIFFENING. Norris F. Dow, Charles Libove, and Ralph E. Hubka. 1954. ii, 24p. diagrs., tab. (NACA Rept. 1195. Supersedes RM L53E13a)

Formulas are derived for the elastic constants of plates with integral ribbing. The constants, which include the effectiveness of the ribs for resisting deformations other than bending and stretching in their longitudinal directions, are defined in terms of four coefficients, and methods for the evaluation of these coefficients are discussed. Four of the more important elastic constants are predicted by these formulas and are compared with test results.

NACA Rept. 1199

A STUDY OF THE PROBLEM OF DESIGNING AIRPLANES WITH SATISFACTORY INHERENT DAMPING OF THE DUTCH ROLL OSCILLATION. John P. Campbell and Marion O. McKinney, Jr. 1954. ii, 18p. diagrs., tabs. (NACA Rept. 1199. Supersedes TN 3035)

This paper presents some preliminary results of a theoretical investigation to determine what design features appear most important in designing modern high-performance airplanes to have the greatest possible inherent stability of the Dutch roll oscillation in order that the need for artificial stabilizing devices can be minimized. These preliminary results cover the case of fighter airplanes at subsonic speeds.

NACA Rept. 1200

METHOD FOR STUDYING HELICOPTER LONGITUDINAL MANEUVER STABILITY. Kenneth B. Amer. 1954, ii, 17p. diagrs., photos., tabs. (NACA Rept. 1200. Supersedes TN 3022)

A theoretical analysis of helicopter maneuver stability is made and the results are compared with experimental results for both a single- and a tandem-rotor helicopter. Techniques are described for measuring in flight the significant stability derivatives for use with the theory to aid in design studies of means for achieving marginal maneuver stability for a prototype helicopter.

NACA Rept. 1201

PERFORMANCE AND BOUNDARY-LAYER DATA FROM 12° AND 23° CONICAL DIFFUSERS OF AREA RATIO 2.0 AT MACH NUMBERS UP TO CHOKING AND REYNOLDS NUMBERS UP TO 7.5×10^6. B. H. Little, Jr., and Stafford W. Wilbur. 1954. ii, 23p. diagrs., tabs. (NACA Rept. 1201. Supersedes RM L9H10; RM L9K10; RM L50C02a)

For each of two inlet-boundary-layer thicknesses, performance and boundary-layer characteristics have been determined for a 12°, 10-inch-inlet-diameter diffuser, a 12°, 21-inch-inlet-diameter diffuser, and a 23°, 21-inch-inlet-diameter diffuser. The investigation covered an inlet Mach number range from about 0.10 to the choking Mach number. The corresponding Reynolds numbers, based on inlet diameter, varied from about 0.5×10^6 to 7.5×10^6. Total-pressure losses increased and the static-pressure recovery decreased with increasing inlet-boundary-layer thickness for all three diffusers. Increasing flow rate (increasing Mach and Reynolds number) produced an adverse effect on performance, which became more severe with increasing inlet-boundary-layer thickness or increased diffuser angle.

NACA Rept. 1207

STUDIES OF THE LATERAL-DIRECTIONAL FLYING QUALITIES OF A TANDEM HELICOPTER IN FORWARD FLIGHT. Kenneth B. Amer and Robert J. Tapscott. 1954. ii, 15p. diagrs., photos., tab. (NACA Rept. 1207. Supersedes TN 2984)

Results of flight measurements and pilots' opinions of the forward-flight lateral-directional flying qualities of a tandem helicopter in several different configurations are compared and analyzed. The conclusions are presented in the form of desirable flying-qualities goals applicable to all types of helicopters. Comparison between theoretical analyses and experimental results indicates theory to be a useful tool for studying means of achieving these goals. On the basis of theoretical analyses, possible practical methods of achieving these goals in the tandem helicopter are suggested.

NACA Rept. 1208

A COMPARISON OF THE SPANWISE LOADING CALCULATED BY VARIOUS METHODS WITH EXPERIMENTAL LOADINGS OBTAINED ON A 45° SWEPTBACK WING OF ASPECT RATIO 8.02 AT A REYNOLDS NUMBER OF 4.0×10^6. William C. Schneider. 1954. ii, 11p. diagrs., tab. (NACA Rept. 1208. Supersedes RM L51G30)

Experimental force and moment data obtained by pressure measurements on a wing of aspect ratio 8.02, 45° sweepback of the quarter-chord line, taper ratio of 0.45, and NACA 63_1A012 airfoil sections parallel to the plane of symmetry have been compared with the calculated loadings obtained by the standard methods proposed by Weissinger, Falkner, and Multhopp, as well as by variations thereof. On the basis of the present calculations, the Weissinger solution, when the number of control points was increased from 7 (the number suggested by Weissinger) to 15, or the Multhopp solution when using at least 15 control points, resulted in a good compromise between lift-curve slope and load shape, although all of the calculations underestimated the lift-curve slope.

NACA RM 55I30

STATIC SHEAR STRENGTH OF 2117-T4 (A17S-T4) ALUMINUM-ALLOY RIVETS AT ELEVATED TEMPERATURES. W. J. Dewalt and K. O. Bogardus, Aluminum Company of America. January 1956. 12p. diagrs., photo., tabs. (NACA RM 55I30)

Static single shear tests were made of 3/16-inch-diameter 2117-T4 (A17S-T4) aluminum-alloy rivets at elevated temperatures. The maximum test temperature employed was 800° F, and the time at temperature prior to testing ranged from 1/2 hour to 720 hours.

NACA RM E55I28

EFFECT OF DISSOLVED OXYGEN ON THE FILTERABILITY OF JET FUELS FOR TEMPERATURES BETWEEN 300° AND 400° F. Anderson B. McKeown and Robert R. Hibbard. December 1955. 22p. diagrs., photos., tabs. (NACA RM E55I28)

The effect of dissolved oxygen on the filter-clogging characteristics of three JP-4 and two JP-5 fuels was studied at 300° to 400° F in a bench-scale rig, employing filter paper as the filter medium. The residence time of the fuel at the high temperature was approximately 6 seconds. For these conditions, the clogging characteristics of the fuels increased with both increasing temperature and increasing concentration of dissolved oxygen. The amount of insoluble material formed at high temperatures necessary to produce clogging of filters was very small, of the order of 1 milligram per gallon of fuel.

NACA RM E55J04

PRELIMINARY INVESTIGATION OF SEVERAL ROOT DESIGNS FOR CERMET TURBINE BLADES IN TURBOJET ENGINE. III - CURVED-ROOT DESIGN. Benjamin Pinkel, George C. Deutsch, and William C. Morgan. December 1955. 17p. diagr., photos., tabs. (NACA RM E55J04)

Stresses in the root fastenings of turbine blades were appreciably reduced by redesign of the root. The redesign consisted in curving the root to approximately conform to the camber of the airfoil and elimination of the blade platform. Full-scale jet-engine tests at rated speed using cermet blades of the design confirmed the improvement.

NACA TN 3529

THE TRANSONIC CHARACTERISTICS OF 36 SYMMETRICAL WINGS OF VARYING TAPER, ASPECT RATIO, AND THICKNESS AS DETERMINED BY THE TRANSONIC-BUMP TECHNIQUE. Warren H. Nelson, Edwin C. Allen, and Walter J. Krumm. December 1955. 131p. diagrs., photo. (NACA TN 3529. Supersedes RM A53I29)

An investigation was made in the Ames 16-foot high-speed wind tunnel, utilizing the transonic-bump technique to determine the effects of plan-form taper on a series of wings having aspect ratios of 4, 3, and 2, and NACA 63A00X sections with thickness-to-chord ratios of 8, 6, 4, and 2 percent. The Mach number range was 0.6 to 1.1 with a corresponding Reynolds number range of about 1.4 million to 2.0 million. The results indicate that increasing the taper ratio caused only small increases in lift-curve slope except for the wings of highest aspect ratio and thinnest sections. Increasing taper ratio generally increased the overall center-of-pressure travel in going from subsonic to supersonic speeds.

NACA TN 3549

FLIGHT INVESTIGATION AT MACH NUMBERS FROM 0.8 TO 1.5 TO DETERMINE THE EFFECTS OF NOSE BLUNTNESS ON THE TOTAL DRAG OF TWO FIN-STABILIZED BODIES OF REVOLUTION. Roger G. Hart. December 1955. 11p. diagrs., photos., tabs. (NACA TN 3549. Supersedes RM L50I08a)

Values of total-drag coefficient were measured for two fin-stabilized, blunt-nose bodies of revolution in free flight at Mach numbers from 0.8 to 1.5. The blunt-nose bodies were designed by rounding off the sharp noses of bodies, having nose fineness ratios of about 3-1/2, to radii equal to about one-fourth the maximum radii. No increase in the drag of either body was found.

NACA TN 3551

EXPERIMENTAL INVESTIGATION AT LOW SPEED OF EFFECTS OF FUSELAGE CROSS SECTION ON STATIC LONGITUDINAL AND LATERAL STABILITY CHARACTERISTICS OF MODELS HAVING 0° AND 45° SWEPTBACK SURFACES. William Letko and James L. Williams. December 1955. 45p. diagrs., tabs. (NACA TN 3551)

An experimental investigation was made at low speed to determine the effects of fuselage cross section on the static longitudinal and lateral stability characteristics of airplane models having 0° and 45° sweptback surfaces. The results indicate that the shallow-fuselage configurations are the least stable longitudinally, and the deep-fuselage configurations are the least stable directionally.

NACA TN 3556

GRAIN-BOUNDARY BEHAVIOR IN CREEP OF ALUMINUM BICRYSTALS. F. N. Rhines, W. E. Bond, and M. A. Kissel, Carnegie Institute of Technology. December 1955. 56p. diagrs., photos., tabs. (NACA TN 3556)

The gliding of one metal crystal with respect to another parallel to their mutual grain boundary has been studied in pure aluminum bicrystals during isothermal creep at temperatures ranging from 200° to 650° C under static stresses of 10 to 1,600 psi. The motion is spasmodic and begins with an induction period. The mechanism of grain-boundary gliding is described as a coordinated alternation of slip and recovery in a chain of subgrains along the creep boundary. This concept is employed to account both for the rate of primary creep and for the transition from primary to steady-state creep.

NACA TN 3559

LAMINAR SEPARATION OVER A TRANSPIRATION-COOLED SURFACE IN COMPRESSIBLE FLOW. Morris Morduchow, Polytechnic Institute of Brooklyn. December 1955. 32p. diagrs. (NACA TN 3559)

A theoretical analysis of laminar separation in compressible flow over a transpiration-cooled surface maintained at a uniform wall temperature is made. A simple method of calculating the separation point over such a surface for a given adverse pressure gradient, Mach number, wall temperature, and uniform coolant temperature is developed. A numerical example shows the effects of these parameters on the separation point.

NACA TN 3584

FREE-CONVECTION EFFECTS ON HEAT TRANSFER FOR TURBULENT FLOW THROUGH A VERTICAL TUBE. E. R. G. Eckert, Anthony J. Diaguila, and John N. B. Livingood. December 1955. 24p. diagrs. (NACA TN 3584)

Experimental heat-transfer data for the turbulent flow of fluids through stationary vertical tubes with both small and large length-to-diameter ratios (to 40) are compared. The limits of the different flow regions, originally established for a tube with small length-to-diameter ratio, apply on the basis of existing data for a tube with large length-to-diameter ratio.

NACA TN 3588

SUMMARY OF LAMINAR-BOUNDARY-LAYER SOLUTIONS FOR WEDGE-TYPE FLOW OVER CONVECTION- AND TRANSPIRATION-COOLED SURFACES. John N. B. Livingood and Patrick L. Donoughe. December 1955. 33p. diagrs., tabs. (NACA TN 3588)

The solutions presented were determined for conditions prevailing over cooled turbine blades. The principal results are restricted to a Prandtl number at the wall of 0.7 and are presented for large temperature changes through the boundary layer adjacent to a constant-temperature wall and for small temperature changes through the boundary layer adjacent to a wall of either a constant or a variable temperature. Results from the literature for Prandtl numbers up to 5.0 are discussed for a flat porous plate.

NACA TN 3599

TURBULENT HEAT-TRANSFER MEASUREMENTS AT A MACH NUMBER OF 0.87. Maurice J. Brevoort and Bernard Rashis. December 1955. 13p. diagrs. (NACA TN 3599)

An axially symmetric annular nozzle was used to obtain essentially flat-plate data on turbulent-heat-transfer coefficients and temperature-recovery factors for a Mach number of 0.87 and for a Reynolds number range from 9.88×10^6 to 2.09×10^8. The heat-transfer coefficients are slightly higher than theoretical results for a Mach number of 1.0, and they agree with theoretical results for incompressible flow. The temperature-recovery factors decreased from 0.899 at a Reynolds number of 9.88×10^6 to 0.876 at a Reynolds number of 2.09×10^8.

NACA TN 3601

PRESSURE RISE ASSOCIATED WITH SHOCK-INDUCED BOUNDARY-LAYER SEPARATION. Eugene S. Love. December 1955. 32p. diagrs. (NACA TN 3601)

Some recent contributions to the problem of shock-induced separation of the boundary layer are examined, and additional analytical and experimental results are presented. The probable ranges of pressure rises and flow deflections associated with separation are indicated. Consideration is given to the effects of Mach number, adverse pressure gradient, and Reynolds number for laminar boundary layers and to the effects of Mach number, Reynolds number, and ratio of specific heats for turbulent boundary layers.

NACA TN 3602

LABORATORY INVESTIGATION OF AN AUTOPILOT UTILIZING A MECHANICAL LINKAGE WITH A DEAD SPOT TO OBTAIN AN EFFECTIVE RATE SIGNAL. Ernest C. Seaberg. December 1955. 27p. diagrs., photos., tab. (NACA TN 3602. Supersedes RM L9F15a)

The results of a laboratory investigation of a frontlash autopilot are presented in this analysis. The operation of this autopilot is based on the nonlinear principle of utilizing a dead spot in the servomotor feedback linkage to the gyroscope base reference as a means of obtaining a leading control signal. The investigation consists of oscillating-table tests in order to determine the effect of frontlash on the amplitude and phase responses of the system. Roll-simulator tests were also conducted in order to confirm the possibility of stabilization of pilotless aircraft with this type of automatic pilot, and an attempt to bracket the usable range of this autopilot was made by plotting the degree of stability as a function of the aerodynamic roll parameters.

NACA TN 3605

THEORETICAL SPAN LOAD DISTRIBUTIONS AND ROLLING MOMENTS FOR SIDESLIPPING WINGS OF ARBITRARY PLAN FORM IN INCOMPRESSIBLE FLOW. M. J. Queijo. December 1955. 45p. diagrs. (NACA TN 3605)

A method is presented for determining the span load distribution and rolling moment due to sideslip for wings of arbitrary plan form in incompressible flow. The method was used to prepare charts from which the rolling moment due to sideslip can be obtained for wings having a large variety of aspect ratio, sweep, and taper ratio. Calculated values of span loads and rolling moments are compared with those of other theories and with experimental results.

NACA TN 3613

THE PROBLEM OF REDUCING THE SPEED OF A JET TRANSPORT IN FLIGHT. Don D. Davis, Jr. December 1955. 22p. diagrs. (NACA TN 3613)

The distance required to decelerate a high-speed jet transport from the normal operating speed to the design speed for maximum gust intensity (rough-air speed) has been calculated for the case of level flight with the engines idling. This distance was found to be much greater for a jet transport than for a typical piston-engine transport at the same altitude, and the distance was found to increase with altitude up to the altitude for maximum true airspeed. The use of aerodynamic brakes, thrust reversal, or a climbing maneuver is shown to be effective in reducing the distance required to reach the rough-air speed.

Department of Supply (Australian)
TURBULENT BOUNDARY LAYER CONTROL BY RAMPS OR WEDGES. A. V. Stephens and G. A. Collins. May 1955. 19p. diagrs., photos. (Department of Supply. ACA-55)

Part I describes preliminary experiments of a new device for the delay or elimination of turbulent separation. The device redistributes the total pressure in a boundary layer by means of wedge-shaped excrescences on the surface. Part II deals with the continuation of these experiments. The operation of boundary-layer wedges for controlling turbulent separation was investigated in an adverse pressure gradient on the upper surface of a wing. A new type of wedge in the form of a flat ramp was developed. These were applied to various wings and flaps with significant improvements in the lift characteristics. In most of the applications tried, the drag due to the wedges or ramps themselves detracted a large portion from the reduction in drag brought about by the delay of turbulent separation from the flap or wing.

CALCULATION OF THE EFFECT OF CAMBER AND TWIST ON THE PRESSURE DISTRIBUTION AND DRAG ON SOME CURVED PLATES AT SUPERSONIC SPEEDS. G. M. Roper. 1955. 68p. diagrs. (ARC R & M 2794; ARC 13,755. Supersedes RAE Aero 2386)

The shapes of two groups of curved wings are found, such that the thrust loading on the leading edges, particularly near the wing tips, is removed or modified. It is also shown how the shapes of wings of one of the groups can be determined to satisfy certain requirements with respect to camber and twist, or the magnitude of aerodynamic characteristics. The lift, induced drag, and pitching-moment coefficients for some wings of triangular plan form have been calculated, and the results are shown graphically.

WIND-TUNNEL TESTS ON THE NPL 434 NOSE-SLOT SUCTION AEROFOIL. J. Williams, R. C. Bankhurst, and Edna M. Love. 1955. 10p. diagrs., tab. (ARC R & M 2876. Supersedes ARC 14,713; Perf. 897; FM 1690)

Stalling tests were made on the 8-percent-thick section NPL 434, which has been specially designed for nose-slot suction. At the higher suction quantities, the maximum lift of the airfoil was considerably greater than for the Lighthill and Glauert sections previously tested when due allowance was made for the difference in camber. At low suction quantities, there was no improvement. Tests with various slot widths showed that the velocity into the slot as well as the suction quantity was important in relation to high maximum lift, and that the values of $C_{L_{max}}$ achieved with suction were determined more nearly uniquely by the momentum coefficient rather than by the quantity coefficient. Static-pressure measurements made in the slot and ducting indicated that the suction head required at the stall was high, being at least equal to the dynamic head in the slot throat, but that some reduction could be expected from improvements in the slot entry shape.

HIGH-SPEED WIND-TUNNEL TESTS ON SIX WINGS OF 40° SWEEPBACK, WITH VARIOUS SECTION SHAPES. L. N. Holmes and A. B. Haines. 1955. 39p. diagrs., photos., tabs. (ARC R & M 2930; ARC 14,687. Supersedes RAE Aero 2452)

Tests have been made in the Royal Aircraft Establishment high-speed wind tunnel on six wings, all of the same plan form (aspect ratio 3.5, taper ratio 0.4, quarter-chord sweep 40°) and thickness/chord ratio (10 percent) but of different section shapes. Four of the wings had symmetrical sections, one was cambered, and one was twisted with camber varying from root to tip. Of the symmetrical wings, the one with RAE 101 section had a much better performance than the other three (RAE 104, NACA 66A-010, and HSA 1). The steep drag rise with Mach number occurred at a Mach number about 0.02 higher on the RAE 101 wing than on the next best wing. The RAE 101 wing also had a higher lift-curve slope and more regular pitching-moment characteristics.

MEASUREMENTS OF TWO-DIMENSIONAL DERIVATIVES ON A WING-AILERON-TAB SYSTEM WITH A 1541 SECTION AEROFOIL. PART I - DIRECT AILERON DERIVATIVES. K. C. Wight. 1955. 18p. diagrs., tabs. (ARC R & M 2934. Supersedes ARC 15,292; ARC 0.1017; ARC S & C 2694)

This report presents results obtained for the direct aileron derivatives with the 1541 section, showing the effects of the following variables: frequency parameter, Reynolds number, amplitude of oscillation, position of transition on the wing, and mean aileron angle. Corrections arising from the apparatus are discussed and reference is made to an attempt to measure the direct tab derivatives. Comparison with vortex-sheet theory shows that measured values of stiffness and damping derivatives are approximately 0.6 of the theoretical values.

SUPERSONIC FLOW PAST SLENDER BODIES OF ELLIPTIC CROSS-SECTION. L. E. Graenkel. 1955. 27p. diagrs. (ARC R & M 2954; ARC 15,166. Supersedes RAE Aero 2466)

The theories of supersonic flow past slender, smooth, pointed bodies of arbitrary cross-sectional shape, due to Ward, and of the flow past slender bodies of revolution with discontinuities in profile slope, due to Lighthill, are applied and extended to calculate first approximations for the aerodynamic forces on bodies of elliptic cross section with discontinuities in profile slope. Open-nose bodies are included in this class, but only the external forces are considered. The investigation is restricted to bodies the major axes of whose cross sections are coplanar and whose cross sections have constant eccentricity. General expressions are deduced for the wave drag, lift, induced drag, and pitching moments of such bodies.

PRESSURE DISTRIBUTIONS ILLUSTRATING FLOW REATTACHMENT BEHIND A FORWARD MOUNTED FLAP. E. C. Maskell. 1955. 22p. diagrs., tab. (ARC CP 211)

Pressure distributions, for M = 0.3, at midspan of a 5-percent chord split flap mounted on an NACA 0015 airfoil are presented from results previously obtained by Clarke in 1946. Two basic types of pressure distribution are identified. These are associated with fully detached flow behind the flap and with reattachment of the flow to the wing surface. An intermediate type, corresponding to reattachment in the neighborhood of the wing trailing edge, is also identified. The physical nature of the flow behind a flap is considered, and some ideas on the mechanism of reattachment are suggested.

INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS - HYDRODYNAMIC STABILITY. PART 2 - THE EFFECT OF CHANGES IN THE MASS, MOMENT OF INERTIA AND RADIUS OF GYRATION ON LONGITUDINAL STABILITY LIMITS. J. K. Friswell, A. G. Kurn, and D. M. Ridland. 1955. 34p. diagrs., photos., tab. (ARC CP 202)

Effects of varying load, moment of inertia, and radius of gyration on the stability limits of a high length-to-beam-ratio dynamic model have been ascertained. A theoretical analysis has been compared with experimental results. The effects on the limits of a change from a velocity to a draught base have also been considered. It has been found that the load is the most critical factor, and that provided the load is kept constant increasing the moment of inertia has little effect on the limits. There was good agreement between theory and experiment.

INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS - HYDRODYNAMIC STABILITY. PART 6 - THE EFFECT OF FOREBODY WARP ON STABILITY AND SPRAY CHARACTERISTICS. D. M. Ridland. 1955. 34p. diagrs., photos., tabs. (ARC CP 203)

The effects of forebody warp on stability, spray, and elevator effectiveness are deduced from the results of tests on three models of length-beam ratio 11, which were alike in every respect except that of forebody warp, the angle of dead rise being increased at the rate of 0°, 4°, and 8° per beam, respectively. It was found that forebody warp considerably improved longitudinal stability and spray characteristics, impaired directional stability slightly, and increased elevator effectiveness. The best configuration was that with 8° of forebody warp per beam.

SOME NOTES ON THE CALCULATION OF PRESSURE PICK-UP SENSITIVITY AND THE CONDITIONS FOR MAXIMUM SENSITIVITY AND THE DEVELOPMENT OF A MINIATURE PRESSURE PICK-UP. J. K. Friswell. 1955. 46p. diagrs., photos. (ARC CP 199)

A theoretical analysis is made of the sensitivity of a pressure pickup of the strain-gaged cantilever type and of the conditions for maximum sensitivity. Two different configurations are treated and the effect of tension in the diaphragm is also considered. An account is given of experiments carried out in order to verify the analysis and to observe the behavior outside the range of validity of the theory. Suggestions are made for practical pickup design based on both theory and experiment and details are given of the construction of a miniature pressure pickup of the type considered in the theoretical treatment.

FURTHER EXPERIMENTS WITH A SLOTTED-WALL TEST SECTION. Friedrich Vandrey. 1955. 16p. diagrs. (ARC CP 207)

As shown previously, a slotted-wall test section is especially suitable for a water tunnel intended for the testing of long models. The present report deals with the transition from this type of test section to the diffuser. The main results are: The optimum diameter of the diffuser entry is 10 percent greater than the diameter of the nozzle (for 30 percent losses in the test section, less for smaller losses). A gap should be left between the end of the slotted wall and the diffuser entry. A model in the test section has very little influence on the pressure in the diffuser entry. Experiments both in air and water are in good agreement.

Aeronautical Research Council (Gt. Brit.)
INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS - HYDRODYNAMIC STABILITY. PART 10 - THE EFFECT OF AFTERBODY LENGTH ON STABILITY AND SPRAY CHARACTERISTICS. D. M. Ridland. 1955. 35p. diagrs., photos., tabs. (ARC CP 204)

The effects of afterbody length on stability, spray, and elevator effectiveness are deduced from the results of tests on four models of the series which were alike in every major respect except that of afterbody length. The models had afterbody lengths of 4, 5, 7, and 9 beams, respectively. Increasing afterbody length improved the disturbed stability characteristics considerably, made no effective overall change in the undisturbed qualities, and reduced trim generally; it impaired spray characteristics and directional stability and reduced elevator effectiveness.

CORROSION AND PROTECTION OF MAGNESIUM ALLOYS CONTAINING ZIRCONIUM. H. G. Cole. June 1955. 17p. photos., tabs. (RAE Tech. Note Met. 222)

Seawater spray corrosion tests showed that magnesium zirconium type alloys had a corrosion resistance similar to that of ordinary purity magnesium aluminum alloys. Chromate treatment alone was less effective on magnesium zirconium alloys, but chromating followed by paint was as effective as on magnesium aluminum alloys; this result emphasizes the importance of durable paint. Substantial dark brown films deposited by the M. E. L. chrome-manganese bath gave approximately the same results as films formed in bath iii of D. T. D. 911A. High corrosion resistance was again shown by high purity magnesium aluminum alloys in both cast and sheet form.

THE CALCULATION OF THE PRESSURE DISTRIBUTION ON THE SURFACE OF THICK CAMBERED WINGS AND THE DESIGN OF WINGS WITH GIVEN PRESSURE DISTRIBUTIONS. J. Weber. June 1955. 104p. diagrs., tabs. (RAE Aero 2548)

This report is a further contribution toward solving the problem of calculating the pressure distribution over the surface of swept wings of any section shape in inviscid incompressible flow. Wings with symmetrical airfoil sections and cambered wings with a special type of camberline have already been dealt with in references 1 to 7. This report deals with thick cambered wings of any section shape and also with the inverse problem of designing airfoils which have prescribed velocity distributions. As the general method is so organized that particular solutions are built up of a few basic solutions, so also in the present case only the basic cases of the two-dimensional airfoil and the center section of swept wings need be treated in detail. A simple calculation method, suitable for practical application, is derived by approximating to the integral expressions for the unknown quantities (velocity increment or section ordinate or the slope of the section) by finite sums over the given section ordinates or velocity increments and tabulating the required coefficients. For the two-dimensional airfoil, a comparison is made with exact results, which shows that the accuracy is sufficient for practical purposes.

VARIATIONS IN THE STRENGTH OF ALUMINIUM ALLOY SHEET. D. T. Jones. July 1955. 11p. diagrs. (RAE Tech. Note Structures 171)

In the design of aircraft structures allowance is made for variation in the material strength of sheet but the thickness of the sheet is usually assumed to be constant at the nominal value for the gage used. Thickness variation may appreciably affect the tensile strength of nominally identical pieces of sheet, especially when the tolerance range in thickness is wide. A method is given in this note for calculating the distribution of strength when the mean and scatter of material strength and the mean and scatter of thickness of pieces are known. Expressions are given for the mean and scatter in strength of pieces and, for those cases where the distribution of the strength can be taken as normal, design values can readily be deduced from the expressions.

A SAFETY DEVICE FOR DOUBLE LEVER TYPE CREEP TESTING MACHINES. T. Thorley. September 1955. 8p. diagrs. (NGTE Memo. M. 194)

The device described in this memorandum has been designed in order to protect double lever creep testing machines and test specimens from damage in the event of furnace failure or power shutdown. This danger arises from the contraction of the pull rod/specimen assembly consequent upon the reduction of temperature resulting from furnace failure. Due to the double lever system, a small amount of movement of the pull rod end of the lower lever results in a large movement of the free end of the upper lever. As the travel of the upper lever is limited by a stop, only a small contraction of the pull rod/specimen assembly can occur before the lever contacts the stop. Once this occurs, any further contraction results in forces of considerable magnitude which may damage either the machine or test piece.

EXPERIMENTS ON A SLOTTED-WALL WORKING SECTION IN A WIND TUNNEL. F. Vandrey and K. Wieghardt. 1955. 17p. diagrs. (ARC CP 206)

The present investigation was undertaken in order to develop a test section for a planned water tunnel with the correction properties of a free jet, but with a considerably greater length than a conventional open working section. The experiments were carried out in air (V = 96 fps) with a jet of 5-inch diameter and 30-inch length, enclosed in a cage of 16 longitudinal rods with an opening ratio of 18 percent of the total boundary. The cage was surrounded by a rigid cylinder of 12-1/2 inch diameter representing the outer boundary of the water tunnel. The main results were: The velocity distributions of the jet in the cage are about the same as in a free jet at half the distance from the nozzle. The static pressure in the cage is constant. Pressure distributions of models in the cage are the same as in a free jet. Even considerable alterations of the design and deformations of the cage have practically no influence on the results.

Aeronautical Research Council (Gt. Brit.)
OPTICAL CHARACTERISTICS OF LAMINATED CAMERA WINDOWS. A. C. Marchant and B. M. Mathieson. 1955. 22p. diagrs., photos., tabs. (ARC CP 210)

Tests were made on windows of both plane and spherical form. Photographic tests of their effect upon the resolving power of an associated camera system have been carried out. The wedge angle of the windows has been measured, and the surface flatness and internal homogeneity of the plane windows tested; while the effects of the curved windows, upon the correction of the camera lens associated with them, have been assessed visually. It is concluded that the laminating process does not, in itself, introduce deleterious effects on optical performance. Plane windows may introduce a focal shift which will reduce resolving power. Curved windows are shown to reduce overall resolution through the introduction of astigmatism and field curvature.

FULL SCALE MEASUREMENTS OF IMPACT LOADS ON A LARGE FLYING BOAT (SUNDERLAND MK. 5) PART II - RESULTS FOR IMPACTS ON MAIN STEP. J. A. Hamilton. 1955. 53p. diagrs., tabs. (ARC CP 205)

Full-scale measurements of landing impact forces and pressures have been made on the hull of a Sunderland Mk. 5 flying boat (weight 50,000 lb) in order to provide basic information on the agreement between experiment and the latest available impact theories. The experiments were arranged to give impact conditions as near as possible to those assumed in theory. The results revealed a marked discrepancy between the form of the total impact-time curve predicted by the theory, and that measured on the aircraft. In particular, the measurement of time to reach maximum impact force was about twice that indicated by theory. The magnitudes of the theoretical and measured maximum impact forces were in reasonable agreement.

AN ANALYSIS OF AERODYNAMIC DATA ON BLOWING OVER TRAILING EDGE FLAPS FOR INCREASING LIFT. J. Williams. 1955. 33p. diagrs., tab. (ARC CP 209)

Results on blowing over trailing-edge flaps are discussed and the force measurements from wind-tunnel tests are correlated in terms of the blowing-moment coefficient. Simple methods are tentatively suggested for the practical prediction of the lift increment (at constant α) attainable on finite wings, and the associated increase in pitching moment. Theoretical curves, relating to compressible isentropic flow through the blowing slot, are presented for the determination of the various blowing coefficients in terms of the blowing-pressure ratio. For sweptback wings in particular, more experiments are needed to establish a satisfactory method of prediction and to determine the optimum blowing configuration. The change in wing stalling angle due to blowing over trailing-edge flaps also warrants further investigation.

TURBULENCE ENCOUNTERED BY COMET 1 AIRCRAFT. J. R. Heath-Smith. May 1955. 32p. diagrs., tabs. (RAE Structures 179)

Acceleration records have been obtained of the turbulence encountered by B.O.A.C. Comet aircraft in 680,000 miles of operational flying on routes connecting London with South Africa and the Far East. It is shown that turbulence decreases with increasing altitude. Of all gusts greater than 10 ft/sec E.A.S. 91 percent were encountered below 27,500. Above 27,500 feet, about 75 percent of gusts greater than 10 ft/sec E.A.S. occur in cumuliform cloud. In flight sectors where conditions favor the formation of cumuliform cloud, gusts may be several times more numerous on average than over widespread routes.

WEIGHT PREDICTION FOR WINGS OF BOX CONSTRUCTION. M. E. Burt. August 1955. 66p. diagrs., tabs. (RAE Structures 186)

The need for thin wings of high torsional stiffness leads to the use of box construction, in which both bending strength and torsional stiffness are provided by a single structural box. This report gives a method by which the wing weight for four types of box construction can be predicted from data available in the project stage of a new design. The equations are derived mainly on a theoretical basis, supported as far as possible by analysis of actual structures, and are evaluated for aluminum alloy at "room" temperature.

THE BUCKLING UNDER LONGITUDINAL COMPRESSION OF A SIMPLY SUPPORTED PANEL THAT CHANGES IN THICKNESS ACROSS THE WIDTH. E. C. Capey. August 1955. 27p. diagrs. (RAE Tech. Note Structures 174)

An exact solution is obtained for the buckling under longitudinal compression of a simply supported panel made up of three strips in which the central strip differs in thickness from the outer strips. The critical buckling stress is calculated numerically for a number of different ratios between thicknesses and widths of the central and outer strips. Some comparative results are given for the case when the longitudinal edges are clamped.

THE FOULING OF TURBINE BLADING BY THE PRODUCTS OF COMBUSTION OF PULVERISED FUEL. PART III. SIMULATION OF THE FOULING, USING AN INERT MINERAL. R. I. Hodge. October 1955. 36p. diagrs., photos., tabs. (NGTE Memo. M. 237)

Pulverized feldspar was substituted for combustion products in tests under similar conditions. It was found that the erosion rates were of the same order. A similar transition from erosion to deposition of the impacting material at gas temperatures several hundred degrees centigrade below the impacting material fusion point was observed, but only when the dust loading contained submicron sizes. This throws some light on the nature of the deposition mechanism.

FATIGUE OF AIRCRAFT PRESSURE CABINS. Percy B. Walker. (Presented at Anglo-American Conference in Los Angeles, June 1955). September 1955. 33p. diagrs., photos. (RAE Structures 188)

The stress pattern in a pressure cabin is first discussed, mainly with respect to cabin-pressure loading. The various other aircraft loading actions contributing to fatigue are then considered and attention is drawn to those which appear most important. The report is concluded by a study of a technique of fatigue testing complete aircraft under cabin-pressure and wing-loading cycles, and examples are given of typical failures of the pressure cabin. RAE test apparatus is described and problems of technique are discussed. The paper concludes with a description of some of the modes of failure that have been produced on a Comet fuselage now available for research purposes.

WIND TUNNEL TESTS ON A 6 FT DIAMETER HELICOPTER ROTOR. T. B. Owen, R. Fail, and R. C. W. Eyre. 1955. 33p. diagrs., tabs. (ARC CP 216)

Thrust, torque, and flapping angle have been measured on a 6-foot diameter rotor over a range of blade angle, shaft inclination, and tip speed ratio for comparison with the 12-foot diameter rotor previously tested in the 24-foot tunnel. In addition to the tests in the 24-foot tunnel, the 6-foot diameter rotor was also tested in the No. 2 11-1/2 foot tunnel to investigate tunnel constraint. Brief investigations were made of support interference and blade twisting. Blade stalling has larger effects on the 6-foot diameter rotor but owing to the progressive nature of the phenomenon it is not possible to define any precise limits to the ranges of validity of the results on the two rotors.

STRESS CONSIDERATIONS IN THE DESIGN OF PRESSURISED SHELLS. E. H. Mansfield. 1955. 27p. tab. (ARC CP 217)

This report considers the stresses developed under internal pressure in thin-walled shells of spherical, cylindrical, or conical form. Formulas are presented for predicting the maximum stresses in a spherical shell with a reinforced circular opening, with a cap of greater thickness; and a cylindrical shell with stringers and closely spaced frames, stringers and widely spaced frames, and end caps of various forms. The feasibility of neutral holes in shells which have a developable surface has been ascertained and investigated in detail for the cylindrical and conical shells. A simple formula is given to allow for the reduced efficiency of reinforcement on one side only of the shell wall.

THE EFFECT OF TIGHT CLAMPING ON THE FATIGUE STRENGTH OF JOINTS. W. A. P. Fisher and W. J. Winkworth. 1955. 10p. diagrs., photos. (ARC R & M 2873; ARC 14,919. Supersedes RAE Structures 121)

The effect of clamping on the fatigue strength of joints in aluminum alloy is investigated experimentally. Tests on Z-section stringers connected to long, slotted cleats give an endurance for tightly clamped joints about nine times that for unclamped joints. Tests of bolted joints in aluminum alloy sheet material show still greater improvement for very tight clamping. In both series of tests, the clamping tends to cancel the weakness in fatigue of a loaded hole. Tight clamping is considered to have many applications in design of aircraft joints from the standpoint of fatigue strength.

N-40512*

Aeronautical Research Council (Gt. Brit.) CALCULATION OF THE PRESSURE DISTRIBUTION OVER A WING AT SONIC SPEEDS. K. W. Mangler. 1955. 55p. diagrs., tab. (ARC R & M 2888; ARC 14,642. Supersedes RAE Aero 2439)

A method is developed for the calculation of the pressure distribution and the aerodynamic forces and moments acting on a wing at angle of attack, a wing in (steady) roll, and a wing in (steady) pitch. The calculation is based on the assumption of an inviscid potential flow and is restricted to small α and thickness ratio, so that the quadratic terms in the perturbation velocities are neglected. The results are valid either for any Mach number for wings of small aspect ratio, or for any aspect ratio for sonic speeds. The aerodynamic coefficients and stability derivatives for a wing family are given in charts. It is indicated that the plan form of the wing is of similar importance as regards the pressure distribution at sonic speeds as the chordwise section of a wing of larger aspect ratio at subsonic speeds.

Marine Aircraft Experimental Establishment (Gt. Brit.) IMPACT MEASUREMENTS ON A LARGE MODEL OF A REPRESENTATIVE LAND-PLANE FUSELAGE ON WATER. J. E. Allen. October 1954. 69p. diagrs., photos., tabs. (MAEE F/Res/264)

An experimental investigation has been made into splash-up, impact pressures, and impact forces occurring during controlled alightings on smooth water of a landplane fuselage of elliptical cross-section. Pressure distributions are presented for several landings over a range of initial attitudes and at flight-path angles down to 1.5. The acceleration results are of limited usefulness due to imperfections in the apparatus. Photographs are included of the external spray formation. Results are not generally applicable to design cases for ditching until a rational theory of impact of fuselage shapes be made available.

NACA RM A50L07

CHARACTERISTICS OF FLOW OVER INCLINED BODIES OF REVOLUTION. H. Julian Allen and Edward W. Perkins. March 5, 1951. 47p. diagrs., photos. (NACA RM A50L07)

Experimental force, moment, and center-of-pressure variations for a large number of bodies of revolution have been compared with the theoretical results based on NACA RM A9I26, 1949. It is shown that the lift and drag characteristics are fairly accurately predicted by the theory, but that the actual center of pressure is more rearward than the theory indicates. Visual flow studies and pressure distributions have shown that the development of the cross flow with distance along an inclined body of revolution is somewhat similar to the development with time of the flow about a circular cylinder impulsively set in motion from rest.

NACA RM A51L03

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF AN AIRPLANE CONFIGURATION WITH AN ASPECT RATIO 2 TRIANGULAR WING AND AN ALL-MOVABLE HORIZONTAL TAIL - LATERAL CHARACTERISTICS. David Graham and David G. Koenig. February 1952. 38p. diagrs., 2 tabs. (NACA RM A51L03)

An investigation has been made to determine the low-speed lateral characteristics of a triangular-wing airplane model. The model consisted of an aspect ratio 2 triangular wing in combination with a fuselage of fineness ratio 12.5; a thin, triangular, vertical tail with a constant-chord rudder; and a thin, unswept, all-movable horizontal tail. The wing had an NACA 0005 modified section and was equipped with partial-span, slotted, trailing-edge flaps. Tests were made with the wing alone, wing-fuselage, and wing-fuselage-vertical-tail configurations in addition to the tests of the complete model. The Reynolds number, based on the wing mean aerodynamic chord, was approximately 14.6×10^6 and the Mach number was 0.13. The results of the tests are presented without analysis.

NACA RM A51L17

DOWNWASH AND SIDEWASH FIELDS BEHIND CRUCIFORM WINGS. John R. Spreiter. January 1952. 18p. photos., diagrs. (NACA RM A51L17)

A brief account is presented of the results of theoretical and experimental investigations of the flow fields behind lifting plane and cruciform wings. Particular attention is focussed on wings of low aspect ratio. It is shown that the deformation of the vortex sheet behind a plane wing consists essentially of a rolling up at the edges. For banked cruciform wings, however, it is shown that, in addition to this effect, the vortices from the upper wing tips pass downward between those from the lower tips. Certain anomalous behaviors of the pitching-moment characteristics of a typical missile configuration are shown to be explainable on the basis of these results.

NACA RM A52L15

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF AN AIRPLANE CONFIGURATION WITH AN ASPECT RATIO 3 TRIANGULAR WING AND AN ALL-MOVABLE HORIZONTAL TAIL - LONGITUDINAL AND LATERAL CHARACTERISTICS. David G. Koenig. April 1953. 61p. diagrs., photos., 4 tabs. (NACA RM A52L15)

Force tests were made with an aspect-ratio-3 triangular wing fuselage-tail configuration with and without horizontal tail. Characteristics at zero sideslip were obtained with the tail located at three vertical positions above the extended wing-chord plane (0, 0.21, and 0.41 wing semispan) for one longitudinal distance aft of the wing. Sideslip data were obtained with the horizontal tail in the extended wing-chord plane. The use of partial-span, slotted, trailing-edge wing flaps or the horizontal tail as a lateral control was investigated. The Reynolds number based on the wing mean aerodynamic chord was 12.8×10^6 and the Mach number was 0.13. The results of the tests are presented without analysis.

NACA RM A52L16

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF TWO AIRPLANE MODELS HAVING ASPECT RATIO 2 TRAPEZOIDAL WINGS OF TAPER RATIOS 0.33 AND 0.20. Ralph W. Franks. February 1953. 56p. diagrs., photos., 3 tabs. (NACA RM A52L16)

Tests were made of two trapezoidal-wing airplane models. Each model consisted of a trapezoidal wing in combination with a fuselage of fineness ratio 12.5, a thin, triangular, vertical tail with a constant chord rudder, and a thin, unswept, all-movable horizontal tail. Tests were made with the horizontal tail at each of three vertical positions with respect to the extended wing-chord plane, and with the horizontal tail removed. The wings had an NACA 0005 modified section and were equipped with slotted, trailing-edge flaps. For both models, the flaps were tested as high-lift devices and as lateral controls; the horizontal tail was tested as a lateral control on one of the models. The Reynolds number for the tests was approximately 12 million and the Mach number approximately 0.13.

NACA RM A52L16a

A FLIGHT INVESTIGATION OF THE EFFECT OF LEADING-EDGE CAMBER ON THE AERODYNAMIC CHARACTERISTICS OF A SWEPT-WING AIRPLANE. Seth B. Anderson, Frederick H. Matteson, and Rudolph D. Van Dyke, Jr. February 1953. 23p. diagrs., photos., tab. (NACA RM A52L16a)

Flight measurements were made on a swept-wing aircraft with a wing modified to have forward camber and increased leading-edge radius. Maximum lift at low speed, stalling characteristics, drag and longitudinal stability were measured.

NACA RM A53A30a

THE EFFECTS OF COMPRESSIBILITY ON THE UPWASH AT THE PROPELLER PLANES OF A FOUR-ENGINE TRACTOR AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. Armando E. Lopez and Jerald K. Dickson. April 1953. 38p. diagrs., photos., tab. (NACA RM A53A30a)

The upflow angles at the horizontal center lines of the propeller planes were measured at Mach numbers up to 0.92 on a wing-fuselage-nacelle combination and on an isolated nacelle. A comparison is made between the experimental and theoretical values of the variation of the upwash angle with angle of attack.

NACA RM A53H18a

THEORY OF WING-BODY DRAG AT SUPERSONIC SPEEDS. Robert T. Jones. September 1953. 11p. diagrs. (NACA RM A53H18a)

The relation of Whitcomb's "area rule" to the linear formulas for wave drag at slightly supersonic speeds is discussed. By adopting an approximate relation between the source strength and the geometry of a wing-body combination, the wave-drag theory is expressed in terms involving the areas intercepted by oblique planes or Mach planes. The resulting formulas are checked by comparison with the drag measurements obtained in wind-tunnel experiments and in experiments with falling models in free air. Finally, a theory for determining wing-body shapes of minimum drag at supersonic Mach numbers is discussed and some preliminary experiments are reported.

NACA RM A53J23

THE EFFECTS OF OPERATING PROPELLERS ON THE LONGITUDINAL CHARACTERISTICS AT HIGH SUBSONIC SPEEDS OF A FOUR-ENGINE TRACTOR AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. Fred B. Sutton and Fred A. Demele. January 1954. 106p. diagrs., photo., 11 tabs. (NACA RM A53J23)

Wing-tunnel tests were conducted in the Ames 12-foot pressure wind tunnel through ranges of angles of attack and model thrust coefficients at Mach numbers from 0.60 to 0.90 at Reynolds numbers of 1,000,000 and 2,000,000. The effects of varying propeller blade angle and of varying the vertical height of the horizontal tail were determined. The overall effects of operating propellers on the longitudinal characteristics were small. Propeller normal-force effects were predicted with good accuracy.

NACA RM A53L03

WIND-TUNNEL INVESTIGATION OF THE EFFECT OF CLIPPING THE TIPS OF TRIANGULAR WINGS OF DIFFERENT THICKNESS, CAMBER, AND ASPECT RATIO - TRANSONIC BUMP METHOD. Horace F. Emerson. February 1954. 183p. diagrs., photo., 2 tabs. (NACA RM A53L03)

Transonic aerodynamic characteristics are presented for four basic triangular wings having aspect ratios of 2.0, 2.5, 3.0, and 4.0, and for these wings when their tips were progressively clipped to provide taper ratios of 0.1, 0.2, 0.3, 0.4, and in some cases 0.5. The NACA 63A00X profile was used with thickness-to-chord ratios of 0.02, 0.04, and 0.06. In addition, a wing with the NACA 63A(1.5)04 section was tested for each aspect ratio investigated. The Mach number range extended from 0.60 to 1.10, corresponding to a test Reynolds number range from 1.85 million to 2.90 million. Lift, drag, and pitching-moment coefficients are presented for each of the wings.

NACA RM A53L17

THE TRANSONIC CHARACTERISTICS OF UNSWEPT WINGS HAVING ASPECT RATIOS OF 4, SPANWISE VARIATIONS IN THICKNESS RATIO, AND VARIATIONS IN PLAN-FORM TAPER - TRANSONIC-BUMP TECHNIQUE. Warren H. Nelson. March 1954. 29p. diagrs., photo. (NACA RM A53L17)

Lift, drag, and pitching-moment data are presented for three unswept wings having aspect ratios of 4, taper ratios of 1.0, 0.5, and 0.2, NACA 63A006 sections at the root, and NACA 63A002 sections at the tip. The Mach number range of the tests was from 0.6 to 1.1, corresponding to a Reynolds number range from 1.4 million to 1.9 million. The results indicate that near a Mach number of 1.0, the drag can be correlated effectively in terms of thickness ratio with the drag of wings having a constant thickness ratio if a weighted thickness ratio is used.

NACA RM A53L29

EFFECTS OF OPERATING PROPELLERS ON THE WING-SURFACE PRESSURES OF A FOUR-ENGINE TRACTOR AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK. Carl D. Kolbe and Frederick W. Boltz. April 1954. 133p. diagrs., photo., 19 tabs. (NACA RM A53L29)

Measurements have been made to evaluate the effects of operating propellers and of nacelles on the wing-surface pressures on a semispan model of a four-engine tractor airplane configuration in the Ames 12-foot pressure wind tunnel. Tabulated pressure data for nine spanwise stations on the wing are presented for the model with the propellers operating and with the propellers removed. Section normal-force coefficients, section pitching-moment coefficients, and the spanwise distribution of loading are presented for selected conditions. Comparative plots of the overall force data are also presented. The tests were conducted through a range of angles of attack and a range of thrust coefficients (up to 0.8 per propeller) at Mach numbers from 0.082 to 0.90 for Reynolds numbers ranging from 1,000,000 to 8,000,000.

NACA RM A53L29a

EFFECTS OF TWO SPINNER SHAPES ON THE PRESSURE RECOVERY IN AN NACA 1-SERIES D-TYPE COWL BEHIND A THREE-BLADE PROPELLER AT MACH NUMBERS UP TO 0.80. Ashley J. Molk and Robert M. Reynolds. March 1954. 34p. diagrs., photo., tab. (NACA RM A53L29a)

The cowl and propeller were tested with an NACA 1-series spinner and a more nearly conical spinner to determine the effects of spinner shape on the pressure recovery in the cowl at Mach numbers from 0.20 to 0.80 and inlet velocity ratios from 0.29 to 1.37. Tests were made with the propeller removed and with the propeller operating at blade angles from 33° to 58.5° and advance ratios from 0.79 to 4.60. Tests were conducted at an angle of attack of 0° and at a Reynolds number of 1.17 million based on the maximum diameter of the cowl. Recoveries obtained with the more nearly conical spinner were higher than with the NACA 1-series spinner for all test conditions.

NACA RM A54F14

ANALYSIS OF WIND-TUNNEL TESTS AT LOW SPEEDS OF A FOUR-ENGINE PROPELLER-DRIVEN AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK. George G. Edwards and Donald A. Buell. October 1954. 137p. diagrs., photos., 2 tabs. (NACA RM A54F14)

Experimental data published in NACA RM A53I28 are analyzed. The effects of operating propellers on the longitudinal characteristics of the model are separated into various components to illustrate the origin, nature, and intensity of each. The analysis indicates certain configuration changes which would reduce the adverse effects of propellers on the longitudinal stability.

NACA RM A54J19

APPLICATION OF WING-BODY THEORY TO DRAG REDUCTION AT LOW SUPERSONIC SPEEDS. Barrett S. Baldwin, Jr., and Robert R. Dickey. January 1955. 42p. (NACA RM A54J19)

A method for extending to higher Mach numbers the region of low drag attainable for wing-body combinations by use of the transonic area rule is developed and examined experimentally. It is found that the drag depends upon the longitudinal distributions of area and moments of area about the body axis.

NACA RM A55A06a

A COMPARISON OF TWO METHODS FOR COMPUTING THE WAVE DRAG OF WING-BODY COMBINATIONS. Alberta Alksne. April 1955. 32p. diagrs. (NACA RM A55A06a)

Computations of wave drag based on linearized theory have been performed for four wing-body combinations and the results are compared with experimental data. Two computational techniques for evaluating the integrals in the theoretical expressions for wave drag are discussed. Advantages and disadvantages of each are pointed out.

NACA RM A55A18

THE WAVE DRAG OF ARBITRARY CONFIGURATIONS IN LINEARIZED FLOW AS DETERMINED BY AREAS AND FORCES IN OBLIQUE PLANES. Harvard Lomax. March 1955. 16p. (NACA RM A55A18)

The wave drag of any object in a steady (linearized) supersonic flow is shown to be identical to the average wave drag of a series of equivalent bodies of revolution, the streamwise gradient of normal cross-sectional areas of which are given by the streamwise gradients of oblique cross-sectional areas of the object plus terms proportional to the resultant force on the object measured in the same (oblique) planes.

NACA RM A55B07

GENERAL THEORY OF WAVE-DRAG REDUCTION FOR COMBINATIONS EMPLOYING QUASI-CYLINDRICAL BODIES WITH AN APPLICATION TO SWEPT-WING AND BODY COMBINATIONS. Jack N. Nielsen. June 1955. 74p. diagrs. (NACA RM A55B07)

An analysis is made of wave-drag reduction for wing and quasi-cylindrical body combinations produced by changes in cross-sectional shape and in area distribution. The theory, applicable at all supersonic speeds, has been applied to a swept-wing and body combination with sonic leading and trailing edges. A reduction of 22 percent of the wave drag of the winged part of the undistorted combination was achieved by utilizing the optimum axially symmetric indentation, and a further reduction of 42 percent was achieved by distortion of cross-sectional shape.

NACA RM A55B16

A SPECIAL METHOD FOR FINDING BODY DISTORTIONS THAT REDUCE THE WAVE DRAG OF WING AND BODY COMBINATIONS AT SUPERSONIC SPEEDS. Harvard Lomax and Max. A. Heaslet. May 1955. 113p. diagrs., tab. (NACA RM A55B16)

For a given wing and supersonic Mach number, the problem of shaping an adjoining fuselage so that the combination will have a low wave drag is considered. Only fuselages that can be simulated by singularities (multipoles) distributed along the body axis are studied. However, the optimum variations of such singularities are completely specified in terms of the wing geometry.

NACA RM E51L13

ANALYSIS OF COOLANT-FLOW REQUIREMENTS FOR AN IMPROVED, INTERNAL-STRUT-SUPPORTED, AIR-COOLED TURBINE-ROTOR BLADE. Wilson B. Schramm and Alfred J. Nachtigall. February 1952. 26p. diagrs., photo. (NACA RM E51L13)

An analytical evaluation of a new type of air-cooled turbine-rotor-blade design, based on the principle of submerging the load-carrying element in cooling air within a thin high-temperature shell, indicates that this principle of blade design permits the load-carrying element to be operated at considerably lower temperature than that of the enveloping shell. Comparison with an air-cooled shell-supported blade showed that the internal-strut-supported air-cooled blade has greater potentiality to withstand increased stresses that can be anticipated in future engines.

NACA RM E51L19

INVESTIGATION AT MACH NUMBER 1.91 OF SPREADING CHARACTERISTICS OF JET EXPANDING FROM CHOKED NOZZLES. Morris D. Rousso and L. Eugene Baughman. February 1952. 27p. photos., diagrs. (NACA RM E51L19)

The gross spreading characteristics of jets expanding from convergent and convergent-divergent nozzles in the base of a body of revolution with various boattail configurations at a Mach number of 1.91 are presented. It is demonstrated that the temperature profiles of jets expanding into a supersonic stream are considerably smaller than the temperature profiles of jets expanding into quiescent air. The effect on the wake of varying afterbody geometry is shown to be small.

NACA RM E51L26

SOME OBSERVATIONS OF SHOCK-INDUCED TURBULENT SEPARATION ON SUPERSONIC DIFFUSERS. T. J. Nussdorfer. May 1954. 14p. diagrs., photos. (NACA RM E51L26)

A survey of experimental data at supersonic speed indicated that shock-induced separation of a turbulent boundary layer will result for Mach numbers of approximately 1.33 or greater when a theoretical stream static-pressure-rise ratio of approximately 1.89 occurs across a shock interacting with the boundary layer. The significance of this tentative criterion for turbulent boundary-layer separation is discussed with respect to the design of supersonic diffusers.

#NACA RM E53L30a

NACA RM L6J18a

LOW-SPEED WIND-TUNNEL TESTS OF A PILOTLESS AIRCRAFT HAVING HORIZONTAL AND VERTICAL WINGS AND CRUCIFORM TAIL. N. Mastrocola and A. Assadourian. August 19, 1947. 100p. diagrs., photos., tab. (NACA RM L6J18a)

Low-speed tests of a pilotless aircraft were conducted in the Langley propeller-research tunnel to provide information for the estimation of the longitudinal stability and control, to measure the aileron effectiveness, and to calibrate the radome and the Machmeter pitot-static orifices.

NACA RM L7L01

ADDITIONAL RESULTS IN A FREE-FLIGHT INVESTIGATION OF CONTROL EFFECTIVENESS OF FULL-SPAN, 0.2-CHORD PLAIN AILERONS AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS TO DETERMINE SOME EFFECTS OF WING SWEEPBACK, ASPECT RATIO, TAPER, AND SECTION THICKNESS RATIO. Carl A. Sandahl and H. Kurt Strass. April 23, 1948. 31p. diagrs., photos. (NACA RM L7L01)

An aerodynamic-control-effectiveness investigation using free-flight, rocket-propelled test vehicles is being conducted by the Pilotless Aircraft Research Division of the Langley Aeronautical Laboratory. Additional results have been obtained recently which indicate some effects of wing sweepback, aspect ratio, taper ratio, and section thickness ratio on the rolling effectiveness of plain full-span, 0.2-chord, sealed ailerons.

NACA RM L7L22

EFFECT OF A PILOT'S CANOPY ON THE DRAG OF AN NACA RM-2 DRAG RESEARCH MODEL IN FLIGHT AT TRANSONIC AND SUPERSONIC SPEEDS. Paul E. Purser. April 20, 1948. 7p. diagrs., photos. (NACA RM L7L22)

Results of flight tests of an NACA RM-2 drag research model equipped with a pilot's canopy are presented for the Mach number range from 0.85 to 1.4. The canopy added an almost constant increment in drag coefficient of approximately 0.08 (based on the frontal area of the basic body, 0.1364 sq ft) in the Mach number range from 1.0 to 1.4. When the drag coefficients of the canopy-equipped model are based on the frontal area of that model (0.1511 sq ft), they are 5 to 9 percent higher than for the basic model.

NACA RM L8L30

PRELIMINARY WIND-TUNNEL TESTS OF TRIANGULAR AND RECTANGULAR WINGS IN STEADY ROLL AT MACH NUMBERS OF 1.62 AND 1.92. Clinton E. Brown and Harry S. Heinke, Jr. February 17, 1949. 39p. diagrs., photo., tabs. (NACA RM L8L30)

Damping-in-roll coefficients for a series of triangular plan-form wings and two rectangular plan-form wings have been obtained from supersonic tunnel tests. The wings were mounted on a body of revolution and tested at Mach numbers of 1.62 and 1.92.

NACA RM L50L12

INVESTIGATION OF THE EFFECTS OF GEOMETRIC CHANGES IN AN UNDERWING PYLON-SUSPENDED EXTERNAL-STORE INSTALLATION ON THE AERODYNAMIC CHARACTERISTICS OF A 45° SWEPTBACK WING AT HIGH SUBSONIC SPEEDS. Kenneth P. Spreemann and William J. Alford, Jr. March 5, 1951. 91p. diagrs., photos., tabs. (NACA RM L50L12)

An investigation was conducted in the Langley high-speed 7- by 10-foot tunnel through a Mach number range of 0.41 to 0.97 to determine the effects of external-store fineness ratio, store shape, store chordwise position, pylon thickness, pylon length, and pylon sweep angle on the aerodynamic characteristics of a number of underwing pylon-suspended external stores in combination with a 45° sweptback semispan wing and fuselage. The store profiles corresponded to NACA 65A-series bodies of revolution, the pylons were NACA 64A-series airfoil sections, and the wing was an NACA 65A006 airfoil section parallel to the free stream.

NACA RM L51D06

COMPARISON OF ZERO-LIFT DRAGS DETERMINED BY FLIGHT TESTS AT TRANSONIC SPEEDS OF SYMMETRICALLY MOUNTED NACELLES IN VARIOUS SPANWISE POSITIONS ON A 45° SWEPTBACK WING AND BODY COMBINATION. William B. Pepper, Jr., and Sherwood Hoffman. May 23, 1951. 29p. diagrs., photos., tabs. (NACA RM L51D06)

Rocket-powered models were flown at transonic speeds to determine the effect of spanwise nacelle location on the zero-lift drag. Solid nacelles were mounted in symmetrical positions and varied spanwise along a 45° sweptback tapered wing. From these tests, it is apparent that the drag increment associated with adding nacelles to a wing-body combination is largely dependent upon the nacelle location.

NACA RM L51F15

THE EFFECT ON ZERO-LIFT DRAG OF AN INDENTED FUSELAGE OR A THICKENED WING-ROOT MODIFICATION TO A 45° SWEPTBACK WING-BODY CONFIGURATION AS DETERMINED BY FLIGHT TESTS AT TRANSONIC SPEEDS. William B. Pepper. September 1951. 20p. diagrs., photos., 2 tabs. (NACA RM L51F15)

Rocket-powered models were flown at transonic speeds to determine the effect of a thickened wing-root and an indented fuselage modification on the zero-lift drag. The basic configuration consisted of a 45° sweptback wing 9 percent thick and of aspect ratio 6.0 mounted on a fuselage of fineness ratio 10.0. Significant drag variations due to these modifications were noted.

NACA RM L51L07a

PRESSURE MEASUREMENTS ON A BODY OF REVOLUTION IN THE LANGLEY 16-FOOT TRANSONIC TUNNEL AND A COMPARISON WITH FREE-FALL DATA. Joseph M. Hallissy, Jr. March 1952. 19p. diagrs. (NACA RM L51L07a)

Pressure distributions have been obtained on a 10-foot-long body of revolution in the Langley 16-foot transonic tunnel and the results are compared with pressure data obtained by the free-fall method on an identical body. For Mach numbers from 0.74 to 1.00, the data curves show generally good agreement in shape but a small displacement in overall level. For Mach numbers from 1.02 to 1.09 there are increased differences, due to wind-tunnel wall interference.

NACA RM L52D07

SOME EFFECTS OF BODY CROSS-SECTIONAL SHAPE, INCLUDING A SUNKEN-CANOPY DESIGN, ON DRAG AS SHOWN BY ROCKET-POWERED-MODEL TESTS AT MACH NUMBERS FROM 0.8 TO 1.5. William E. Stoney, Jr., and Leonard W. Putland. July 1952. 15p. diagrs., photos. (NACA RM L52D07)

Flight tests were made with two pairs of rocket-propelled bodies of fineness ratio 8.91 to determine the effect of changes in body cross-sectional shape on drag. At supersonic speeds the small differences in drag between the models with the same cross-sectional-area distributions substantiate the predictions of linearized theory that, to the first order, drag is independent of cross-sectional shape.

NACA RM L52G08a

INVESTIGATION OF THE LOW-SPEED AERODYNAMIC CHARACTERISTICS OF A VARIABLE-SWEEP AIRPLANE MODEL WITH A WING HAVING PARTIAL-SPAN CAMBERED-LEADING-EDGE MODIFICATIONS. Robert E. Becht and Andrew L. Byrnes, Jr. September 1952. 47p. diagrs., photos. (NACA RM L52G08a)

An investigation was made to determine the aerodynamic characteristics at low speed of a variable-sweep airplane model with a wing having two interchangeable partial-span leading-edge-camber modifications. A comparison is made with data obtained on the same model incorporating a wing of symmetrical sections and also a fully cambered and twisted wing. Included in the investigation is the effect of partial-span split flaps at the minimum sweep angle of 20°.

NACA RM L52I23

THE EFFECTS OF SWEEPBACK ON LONGITUDINAL CHARACTERISTICS OF A 1/30-SCALE SEMISPAN MODEL OF THE BELL X-5 AIRPLANE AS DETERMINED FROM NACA WING-FLOW TESTS AT TRANSONIC SPEEDS. Joseph J. Kolnick and Robert M. Kennedy. November 1952. 48p. diagrs., photos., tab. (NACA RM L52I23)

Tests were made by the NACA wing-flow method to determine the effect of sweepback angle on the longitudinal characteristics of a 1/30-scale semispan model of the Bell X-5 variable-sweep airplane within the transonic speed range (Mach numbers from 0.70 to 1.05). Lift, drag, and pitching-moment results are presented with wings in the 20°, 30°, 40°, 50°, and 60° positions. A test was also made with the fuselage alone. The Reynolds number was about 1.3×10^6.

NACA RM L52K12

LONGITUDINAL-CONTROL EFFECTIVENESS AND DOWNWASH CHARACTERISTICS AT TRANSONIC SPEEDS OF A 1/30-SCALE SEMISPAN MODEL OF THE BELL X-5 AIRPLANE AS DETERMINED BY THE NACA WING-FLOW METHOD. Norman S. Silsby and Garland J. Morris. January 1953. 48p. diagrs., photos., 2 tabs. (NACA RM L52K12)

An investigation was made at transonic speeds by the NACA wing-flow method to determine the longitudinal control effectiveness and downwash characteristics of a 1/30-scale semispan model of the Bell X-5 airplane with the wings of the model swept back 60°, 40°, and 20°. Lift, drag, and pitching moments were obtained for various angles of attack for several horizontal tail incidences and with tail off for each angle of sweep of the wing. The Reynolds number was about 1.0×10^6.

NACA RM L52L11b

LOW-SPEED LONGITUDINAL CHARACTERISTICS OF AN UNSWEPT HEXAGONAL WING WITH AND WITHOUT A FUSELAGE AND A HORIZONTAL TAIL LOCATED AT VARIOUS POSITIONS AT REYNOLDS NUMBERS FROM 2.8×10^6 TO 7.6×10^6. Gerald V. Foster, Ernst F. Mollenberg, and Robert L. Woods. February 26, 1953. 63p. diagrs., photos., 3 tabs. (NACA RM L52L11b)

An investigation was made in the Langley 19-foot pressure tunnel to determine the low-speed longitudinal characteristics of an unswept wing having hexagonal airfoil sections and aspect ratio of 2.5. This paper includes the results concerning the effect of leading- and trailing-edge flaps on the aerodynamic characteristics of the wing with and without a fuselage. The effects of wing-tip cross-sectional shape and wing trailing-edge thickness and the effect of a horizontal tail located at various vertical and horizontal positions on the longitudinal characteristics of the wing are also shown.

NACA RM L52L18

WIND-TUNNEL INVESTIGATION OF THE STATIC LATERAL STABILITY CHARACTERISTICS OF WING-FUSELAGE COMBINATIONS AT HIGH SUBSONIC SPEEDS. ASPECT-RATIO SERIES. Paul G. Fournier and Andrew L. Byrnes, Jr. February 1953. 26p. diagrs., photos. (NACA RM L52L18)

This report presents the aerodynamic characteristics in sideslip of wing-fuselage combinations having wings of 45° sweepback, a taper ratio of 0.6, aspect ratios of 2, 4, and 6, and an NACA 65A006 airfoil section. The tests covered a Mach number range from 0.4 to 0.95, a Reynolds number range from 1.5×10^6 to 5×10^6, depending upon the wing and Mach number, and an angle-of-attack range from -3° to 24°.

NACA RM L52L24

PRELIMINARY THEORETICAL INVESTIGATION OF SEVERAL METHODS FOR STABILIZING THE LATERAL MOTION OF A HIGH-SPEED FIGHTER AIRPLANE TOWED BY A SINGLE CABLE. Albert A. Schy and Carroll H. Woodling. March 1953. 46p. diagrs., 2 tabs. (NACA RM L52L24)

A theoretical investigation of the lateral stability of a high-speed fighter airplane towed by a long cable indicates several possible methods of stabilization. Calculated motions and characteristic modes show that an automatic control that provides a rolling moment proportional to angle of bank or deflection of a rudder-type surface proportional to a linear combination of transverse acceleration and velocity would give satisfactory lateral stability. Other possible methods of stabilization are also suggested.

NACA RM L52L29

AN EXPERIMENTAL INVESTIGATION OF BOUNDARY INTERFERENCE ON FORCE AND MOMENT CHARACTERISTICS OF LIFTING MODELS IN THE LANGLEY 16- AND 8-FOOT TRANSONIC TUNNELS. Charles F. Whitcomb and Robert S. Osborne. February 1953. 31p. photos., diagrs., tab. (NACA RM L52L29)

Tests of a fuselage-alone and of wing-fuselage configurations having model-to-tunnel cross-sectional-area ratios from 0.0003 to 0.0038 have been conducted in the slotted test sections of the Langley 16-foot and 8-foot transonic tunnels in order to obtain experimental information concerning the effects of boundary interference on force and moment characteristics of typical models at lifting attitudes for Mach numbers from 0.60 to 1.07. The agreement of the test results indicated that boundary-interference effects on the force and moment characteristics of these models were small.

NACA RM L52L29a

THE EFFECTS OF FUSELAGE SIZE ON THE LOW-SPEED LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF A THIN 60° DELTA WING WITH AND WITHOUT A DOUBLE SLOTTED FLAP. John M. Riebe. February 1953. 24p. diagrs., photo., tab. (NACA RM L52L29a)

Results and discussion are presented of a wind-tunnel investigation to determine the effects of fuselage size on the low-speed longitudinal aerodynamic characteristics of a thin delta wing with and without a double slotted flap. Increased fuselage diameter from 0.094 to 0.292 wing span reduced the maximum lift coefficient from 1.40 to 1.01 for the flap-retracted condition and from 1.71 to 1.16 with the flap at 54° deflection and resulted in about a 0.4 reduction in increment of lift at 0° angle of attack for the flap-deflected condition.

NACA RM L53I18b

SOME EFFECTS OF AEROELASTICITY AND SWEEPBACK ON THE ROLLING EFFECTIVENESS AND DRAG OF A 1/11-SCALE MODEL OF THE BELL X-5 AIRPLANE WING AT MACH NUMBERS FROM 0.6 TO 1.5. Roland D. English. November 1953. 21p. diagrs., photos. (NACA RM L53I18b)

An investigation has been made to determine some effects of aeroelasticity and sweepback on the rolling effectiveness and drag of a 1/11-scale model of the variable-sweep Bell X-5 airplane wing. Rolling effectiveness and drag data are presented at Mach numbers from 0.6 to 1.5. Results of the investigation indicate that the Bell X-5 airplane with present wing construction is subject to severe rolling effectiveness losses due to flexibility. Increasing the angle of wing sweepback increases the rolling effectiveness in the Mach number range above 0.65. Increasing the angle of sweepback also decreases the subsonic drag coefficient and increases the Mach number at which transonic drag rise occurs. No effects of flexibility on drag were found.

NACA RM L53L14

STABILITY CHARACTERISTICS AT LOW SPEED OF A VARIABLE-SWEEP AIRPLANE MODEL HAVING A PARTIALLY CAMBERED WING WITH SEVERAL CHORD-EXTENSION CONFIGURATIONS. Robert E. Becht. February 1954. 37p. diagrs., photos. (NACA RM L53L14)

An investigation was made to determine the aerodynamic characteristics at low speed of a model representative of a variable-sweep airplane having a partially cambered wing and chord-extensions of several designs. Included in the investigation is the effect of drooped chord-extensions in conjunction with split flaps on the wing at 20° sweep. In addition, a comparison is made of the stability characteristics of the model with either a partially cambered wing and chord-extensions or a symmetrical wing and slats.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1202

CHARTS RELATING THE COMPRESSIVE BUCKLING STRESS OF LONGITUDINALLY SUPPORTED PLATES TO THE EFFECTIVE DEFLECTIONAL AND ROTATIONAL STIFFNESS OF THE SUPPORTS. Roger A. Anderson and Joseph W. Semonian. 1954. ii, 19p. diagrs., tabs. (NACA Rept. 1202. Supersedes TN 2987)

The stability of a plate under edge compressive stress is analyzed in terms of the deflectional and rotational stiffnesses of one or more longitudinal lines of support between the plate side edges. The results are presented in the form of charts which make possible the determination of the compressive buckling stress of plates supported by members whose stiffness may or may not be defined by elementary beam bending and twisting theory but yet whose effective restraint is amenable to evaluation. The deflectional and rotational restraint provided by longitudinal stiffeners and full-depth webs is discussed, and numerical examples illustrate the application of the charts to the design of wing structures.

NACA Rept. 1204

APPLICATION OF SEVERAL METHODS FOR DETERMINING TRANSFER FUNCTIONS AND FREQUENCY RESPONSE OF AIRCRAFT FROM FLIGHT DATA. John M. Eggleston and Charles W. Mathews. 1954. ii, 24p. diagrs., tabs. (NACA Rept. 1204. Supersedes TN 2997)

A study is presented of several methods for determining the transfer functions and frequency response of aircraft from flight tests. Results obtained from experience in the use of these methods are compared as to time required for application, comparative accuracy, and means for facilitating their use. The studies cover three categories of methods: sinusoidal response, Fourier analysis of transients, and curve-fitting analysis of transients. Three general types of aircraft are used to illustrate the application of these methods.

NACA Rept. 1205

A WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF THRUST-AXIS INCLINATION ON PROPELLER FIRST-ORDER VIBRATION. W. H. Gray, J. M. Hallissy, Jr., and A. R. Heath, Jr. 1954. ii, 37p. diagrs., photo., tab. (NACA Rept. 1205. Supersedes RM L50D13)

Data are presented on aerodynamic excitation of propeller vibration with the thrust axis at two angles of inclination to the airstream. Aerodynamic excitation is calculated and compared with measured values for several conditions. Measured and calculated blade vibratory stresses for several excitation values are presented. The calculated values of exciting force compared well with the measured values at low rotational speeds but not so well at high rotational speeds.

NACA RM E55I29

PERFORMANCE CHARACTERISTICS OF CYLINDRICAL TARGET-TYPE THRUST REVERSERS. Fred W. Steffen and Jack G. McArdle. January 1956. 40p. diagrs., photo. (NACA RM E55I29)

From tests on cylindrical target-type thrust reversers, it was found that the reverser frontal area, lip angle, end-plate angle, and end-plate depth had important effects on reverse-thrust performance. Frontal area, reverser depth, lip angle, and end-plate angle had important effects on the spacing required for unrestricted nozzle flow. For reverse-thrust ratios greater than 64 percent, the reversed flow attached to the 7° cowl in quiescent air. Swept-type cylindrical reversers were generally unstable. The thrust-modulation characteristics of a cylindrical target-type thrust reverser were found to be satisfactory.

NACA TM 1401

DIRECTIONAL STABILITY OF TOWED AIRPLANES. (Die Seitenstabilität eines geschleppten Flugzeuges). W. Söhne. January 1956. 53p. diagrs., tab. (NACA TM 1401. Trans. from Ingenieur-Archiv, v. 21, no. 4, 1953, p. 245-265)

A theoretical investigation of the lateral dynamic stability of an airplane towed by a single towline is presented, and the equations of motion are derived. The effects of variations of towline length, attachment point, lift coefficient, model mass, and angle of climb are examined. In addition, the effects of changes in dihedral, tail area, and damping in roll are studied.

NACA TN 3490

EXPERIMENTAL AND CALCULATED TEMPERATURE AND MASS HISTORIES OF VAPORIZING FUEL DROPS. M. M. El Wakil, R. J. Priem, H. J. Brikowski, P. S. Myers, and O. A. Uyehara, Wisconsin University. January 1956. 82p. diagrs., photos., tab. (NACA TN 3490)

Experimental and calculated mass and temperature histories of drops vaporizing with a constant velocity relative to the air velocity are compared herein, and it is confirmed that, under many conditions, the unsteady state or time required for the drop to reach the wet-bulb temperature is an appreciable portion of the total vaporization time. Work was done to verify or disprove the assumptions used in the computations. Data are presented to show that the assumption of infinite thermal conductivity is valid primarily because of circulation inside the drop.

NACA TN 3534

INSTRUMENTATION FOR MEASUREMENT OF FREE-SPACE SOUND PRESSURE IN THE IMMEDIATE VICINITY OF A PROPELLER IN FLIGHT. William D. Mace, Francis J. Haney, and Edmund A. Brummer. January 1956. 16p. diagrs., photo. (NACA TN 3534)

Instrumentation suitable for the measuring, recording, and subsequent harmonic analysis of the free-space sound pressures in the immediate vicinity of an airplane propeller at flight Mach numbers up to 0.72 is described. The dynamic range of the equipment is 150 to 113 decibels (re 0.0002 dyne/cm^2) and the system frequency response is flat within $\pm$1 decibel from 80 to 1,000 cps. Maximum second-harmonic distortion is less than 3 percent for a sound level of 140 decibels, and the overall accuracy is $\pm$2 decibels.

NACA TN 3545

INVESTIGATION OF THE EFFECT OF SHORT FIXED DIFFUSERS ON STARTING BLOWDOWN JETS IN THE MACH NUMBER RANGE FROM 2.7 TO 4.5. John A. Moore. January 1956. 32p. diagrs., photos. (NACA TN 3545)

An investigation was made at Mach numbers of 2.7, 3.0, 3.5, 4.0, and 4.5 to determine the effect of short fixed convergent-divergent wedge diffusers on the starting characteristics of blowdown jets exhausting to the atmosphere. Wedge diffusers that were extensions of the nozzle contours reduced the overall pressure ratios required for starting to less than one-half the values obtained without a diffuser. The minimum overall pressure ratio required for starting at each Mach number was about twice the value predicted by one-dimensional theory. Central-body diffusers were not so effective in reducing the overall pressure ratio for starting as were the wedge extensions of the nozzle, except at the higher values of diffuser minimum area.

NACA TN 3552

INVESTIGATION OF THE COMPRESSIVE STRENGTH AND CREEP LIFETIME OF 2024-T3 ALUMINUM-ALLOY PLATES AT ELEVATED TEMPERATURES. Eldon E. Mathauser and William D. Deveikis. January 1956. 40p. diagrs., photos., tabs. (NACA TN 3552. Supersedes RM L55E11b)

The results of elevated-temperature compressive-strength and creep tests of 2024-T3 (formerly 24S-T3) aluminum-alloy plates supported in V-grooves are presented. The strength-test results indicate that a relation previously developed for predicting plate compressive strength at room temperature is satisfactory for determining elevated-temperature strength. Creep-lifetime results are presented for the plates in the form of master creep-lifetime curves by using a time-temperature parameter that is convenient for summarizing tensile creep-rupture data. The use of time-dependent stress-strain curves obtained from plate-creep curves for predicting plate-creep failure stresses is investigated.

NACA TN 3553

COMPRESSIVE CRIPPLING OF STRUCTURAL SECTIONS. Melvin S. Anderson. January 1956. 31p. diagrs., tabs. (NACA TN 3553)

A method is presented for calculating crippling stresses of structural sections as a function of material properties and the proportions of the section. The presence of formed or anisotropic material is accounted for by the use of an effective stress-strain curve. The method of analysis applies to many sections for which a procedure for calculating crippling was not previously available.

NACA TN 3560

SPONTANEOUS IGNITION STUDIES RELATING TO LUBRICANTS OF REDUCED FLAMMABILITY. Kenneth T. Mecklenborg, Cincinnati University. January 1956. 17p. diagrs., tabs. (NACA TN 3560)

Increased interest in the use of diesters as lubricants has suggested a study of the influence of the structure of the alcohol moiety on the spontaneous ignition temperature of a series of dialkyl azelates. The determination of spontaneous ignition temperatures has been extended to a number of representative organic phosphorous esters with predominantly aliphatic structures. Determination of the change in spontaneous ignition temperature with composition has been carried out with hydrogenated polyisobutylene in combination with a siloxane and with a phosphonate. The synthesis of polyisobutylene in the lubricant molecular weight range has been improved in yield.

NACA TN 3571

LIFT HYSTERESIS AT STALL AS AN UNSTEADY BOUNDARY-LAYER PHENOMENON. Franklin K. Moore. November 1955. 32p. diagrs., tab. (NACA TN 3571)

With the problem of rotating compressor stall in view, an unsteady boundary-layer calculation is made to find the unsteady increment of lift of a stalled elliptic airfoil in a flow of time-dependent incidence. The analysis indicates a counterclockwise hysteresis loop of the lift curve, the various forms of which are discussed.

NACA TN 3581

EXPERIMENTAL INVESTIGATION OF BLADE FLUTTER IN AN ANNULAR CASCADE. J. R. Rowe and A. Mendelson. November 1955. 24p. diagrs., photos. (NACA TN 3581)

Compressor-type annular cascades of airfoils were investigated to determine effects on flutter characteristics of varying angle of attack, blade chord and spacing, number of blades, and air velocity. Strain-gage, pressure-probe, and hot-wire-anemometer instrumentation was used. Large-amplitude sporadic vibrations in the stall region were encountered and are reported. No rotating stall was observed.

NACA TN 3582

EFFECT OF CLIMB TECHNIQUE ON JET-TRANSPORT NOISE. Warren J. North. January 1956. 19p. diagrs. (NACA TN 3582)

A theoretical investigation of jet-transport climb technique was made to determine the effect of variations in engine thrust and airspeed on sound-pressure levels heard by a ground observer. Reduced noise levels will be obtained when climbing on the steepest flight path consistent with minimum safe airspeed. Additional noise reduction may be obtained by throttling the engine; however, the additional benefit accompanying permissible thrust reduction is small.

NACA TN 3587

IMPINGEMENT OF WATER DROPLETS ON A SPHERE. Robert G. Dorsch, Paul G. Saper, and Charles F. Kadow. November 1955. 29p. diagrs., tab. (NACA TN 3587)

Droplet trajectories about a sphere in ideal fluid flow were calculated. From the calculated droplet trajectories, the droplet-impingement characteristics of the sphere were determined. Impingement data and equations for determining the collection efficiency, the area, and the distribution of impingement are presented in terms of dimensionless parameters. The range of flight and atmospheric conditions covered in the calculations was extended considerably beyond the range covered by previously reported calculations for the sphere.

NACA TN 3590

INVESTIGATION OF FAR NOISE FIELD OF JETS. I - EFFECT OF NOZZLE SHAPE. Edmund E. Callaghan and Willard D. Coles. January 1956. 44p. diagrs., photos. (NACA TN 3590)

The noise generation of jets discharging from convergent (circular, square, rectangular, and elliptical), plug, and convergent-divergent nozzles was investigated. At low jet pressure ratios (less than 2.2) all the nozzles had approximately the same sound field. At high pressure ratios, all the nozzles produced noise having discrete-frequency peaks. Only the convergent-divergent nozzle showed a reduction in both amplitude of the discrete-frequency noise and in total sound power radiated as compared with ordinary convergent nozzles.

NACA TN 3591

INVESTIGATION OF FAR NOISE FIELD OF JETS. II - COMPARISON OF AIR JETS AND JET ENGINES. Willard D. Coles and Edmund E. Callaghan. January 1956. 19p. diagrs., photos. (NACA TN 3591)

A comparison of the noise generation of air jets and turbojet engines was made from data obtained from similar free-field surveys. At jet pressure ratios below or only slightly above that for choked flow, the overall sound power was well represented by the Lighthill parameter, but the sound-power results obtained during afterburner operation were somewhat low. Directional patterns for overall sound pressures were similar for the engines and air jets. Air-jet and engine spectral data were dissimilar because of a dip in the engine-noise spectrum.

NACA TN 3592

AN OIL-STREAM PHOTOMICROGRAPHIC AEROSCOPE FOR OBTAINING CLOUD LIQUID-WATER CONTENT AND DROPLET SIZE DISTRIBUTIONS IN FLIGHT. Paul T. Hacker. January 1956. 36p. diagrs., photos., tabs. (NACA TN 3592)

An airborne cloud aeroscope by which droplet size, size distribution, and liquid-water content of icing and nonicing clouds can be determined has been developed and tested in flight and in wind tunnels with water sprays. The cloud droplets are continuously captured in a stream of oil, which is then photographed. In most cases, droplet size distribution can be obtained from a single photograph. With the droplet size distribution known, the liquid-water content of the cloud can be calculated from the geometry of the aeroscope, the airspeed, and the oil flow rate. The aeroscope is described in detail, and some droplet size distributions and liquid-water contents obtained during tests are presented.

Aeronautical Research Council (Gt. Brit.)
THEORY OF THE BROAD-BLADED PROPELLER. G. I. Ginzel. 1955. 28p. diagrs., tabs. (ARC CP 208)

The standard propeller theory is that of the lifting line and therefore valid for narrow blades only. The present first step towards a theory of the propeller blade as a lifting surface considers, beside the downwash which induces an inclination of flow, the downwash derivative and the corresponding induced camber of the streamlines in the special case of shock free entry of flow at the leading edge. The result is given in the form of a correction factor to be applied to the camber ratio of the section derived by the lifting line theory. The theory of Ludweig and Ginzel is presented with a modified derivation. The influence on the camber correction factor of blade shape, of number of blades, and of circulation distribution over the radius is shown.

Aeronautical Research Council (Gt. Brit.)
THE MANOEUVRABILITY OF AIRCRAFT IN CIRCLING FLIGHT. H. L. Price. 1955. 32p. diagrs. (ARC R & M 2838; ARC 8, 367)

The entry into and recovery from a true banked horizontal turn executed without sideslip or loss of height is investigated. The proper continuous coordination of aileron, rudder, and elevator is deduced for all stages of the maneuver. It is shown that the rolling motion is practically unaffected by the other modes of motion, enabling the kinematics of the rolling mode to be solved in terms solely of the applied aileron movement or stick force. The aileron is regarded as the prime initiator of the turn, operated in some prechosen manner, and the elevator and rudder loads are expressed as functions of the determinable rolling velocity and acceleration. The loads to trim in the final steady turn are found as a particular case. Mathematical analysis is included.

Forest Products Research Lab. (Gt. Brit.)
INVESTIGATIONS INTO GLUES AND GLUING. PROGRESS REPORT EIGHTY-SEVEN - AUGUST 1955. THE COMPARATIVE DURABILITY OF PLYWOOD GLUES IN ENGLAND AND IN NIGERIA (SERIES IV). FIFTH YEAR AND FINAL REPORT. J. F. S. Carruthers and R. W. Hudson. 9p. tabs. (Forest Products Research Lab.)

Beech and gaboon plywood made with phenol-, resorcinol-, melamine-, and fortified and normal urea-formaldehyde types of adhesives has been exposed for five years in two English and two Nigerian environments. The deterioration of all glues is without practical significance for a normally heated workshop. In exposed or outdoor sites the melamine- and fortified and normal urea-formaldehyde adhesives have either failed or show significant deterioration.

COMPOSITE WOOD SECTION. TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. PILLARWOOD - CASSIPOUREA ELLIOTII - TANGANYIKA. (48 POUNDS PER CUBIC FOOT AT 15 PER CENT MOISTURE CONTENT). (PROGRESS REPORT THIRTY-TWO) October 1955. 7p. tabs. (Forest Products Research Lab.)

After processing trials this timber was classed as being unsuitable for British mills due to its small diameter, heaviness, variable color, and poor gluing characteristics. Technically the timber is sound and might be of value in its country of origin.

N-40684*

Forest Products Research Lab. (Gt. Brit.)
COMPOSITE WOOD SECTION. TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. RED MERANTI - SHOREA PARVIFOLIA - BRITISH NORTH BORNEO. (28 POUNDS PER CUBIC FOOT AT 15 PER CENT MOISTURE CONTENT). (PROGRESS REPORT THIRTY-ONE) October 1955. 7p. tabs. (Forest Products Research Lab.)

As a result of drying, gluing, and compression tests, this timber is believed to be suitable for use in British mills for plywood manufacture. Special handling will be required since the veneer is fragile.

N-40685*

Forest Products Research Lab. (Gt. Brit.)
COMPOSITE WOOD SECTION. TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. MUHUHU - BRACHYLAENA HUTCHINISII - TANGANYIKA. (61 POUNDS PER CUBIC FOOT AT 15 PER CENT MOISTURE CONTENT). (PROGRESS REPORT THIRTY) October 1955. 5p. tab. (Forest Products Research Lab.)

After processing trials this species was considered unsuitable for plywood making because of its weight and the difficulty of conversion to veneer.

N-40686*

Forest Products Research Lab. (Gt. Brit.)
COMPOSITE WOOD SECTION. TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. SCOTS PINE - PINUS SYLVESTRIS L. - HOME GROWN. (33 POUNDS PER CUBIC FOOT AT 15 PER CENT MOISTURE CONTENT). DOUGLAS FIR - PSEUDOTSUGA TAXIFOLIA - HOME GROWN. (31 POUNDS PER CUBIC FOOT AT 15 PER CENT MOISTURE CONTENT). (PROGRESS REPORT TWENTY-NINE) July 1955. 24p. tabs. (Forest Products Research Lab.)

Scots pine was found unsatisfactory as plywood due to its poor gluing characteristics and blistering. The Douglas fir was classed unsuitable for plywood making because of knots and the high compression accompanying the pressure needed to obtain an acceptable bond.

N-40687*

Forest Products Research Lab. (Gt. Brit.)
MOISTURE RELATIONS OF COMPOSITE WOOD PRODUCTS. PROGRESS REPORT TWENTY-EIGHT - OCTOBER 1955. THE SUPERFICIAL MOVEMENT OF PLYWOOD. R. A. G. Knight and R. J. Newall. 13p. tabs. (Forest Products Research Lab.)

The superficial movements of plywood of three-ply construction with moisture change have been measured for 69 species. For the two environment changes, the mean averages of the along- and across-grain movements for the 69 species were 1/5 percent and 1/4 percent, respectively. The movement of plywood across the grain was 1/25 that of veneer or solid wood.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1203

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF THE EFFECTS OF CHORDWISE WING FENCES AND HORIZONTAL-TAIL POSITION ON THE STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF AN AIRPLANE MODEL WITH A 35° SWEPTBACK WING. M. J. Queijo, Byron M. Jaquet, and Walter D. Wolhart. 1954. ii, 29p. diagrs., photos., tab. (NACA Rept. 1203. Supersedes RM L50K07; RM L51H17)

Low-speed tests of a model with a wing swept back 35° at the 0.33-chord line and a horizontal tail located well above the extended wing-chord plane indicated static longitudinal instability at moderate angles of attack for all configurations tested. The present investigation was made to determine whether the longitudinal stability could be improved by use of chordwise fences, by lowering the horizontal tail, or by a combination of both.

NACA Rept. 1210

ANALYSIS OF TURBULENT HEAT TRANSFER, MASS TRANSFER, AND FRICTION IN SMOOTH TUBES AT HIGH PRANDTL AND SCHMIDT NUMBERS. Robert G. Deissler. 1955. ii, 14p. diagrs. (NACA Rept. 1210. Supersedes TN 3145)

The expression for eddy diffusivity from a previous analysis was modified in order to account for the effect of kinematic viscosity in reducing the turbulence in the region close to a wall. By using the modified expression, good agreement was obtained between predicted and experimental results for heat and mass transfer at Prandtl and Schmidt numbers between 0.5 and 3000. The effects of length-to-diameter ratio and of variable viscosity were also investigated for a wide range of Prandtl numbers.

NACA Rept. 1212

ANALOG STUDY OF INTERACTING AND NON-INTERACTING MULTIPLE-LOOP CONTROL SYSTEMS FOR TURBULENT ENGINES. George J. Pack and W. E. Phillips, Jr. 1955. ii, 13p. diagrs. (NACA Rept. 1212. Supersedes TN 3112)

An analog investigation of several turbojet control configurations was made. Both proportional and proportional-plus-integral controllers were studied, and compensating terms for engine interaction were added to the control system. Data were taken on the stability limits and the transient responses of these various configurations. Analytical expressions in terms of the component transfer functions were developed for the configurations studied and the optimum form for the compensation terms was determined. It was found that the addition of the integral term, while making the system slower and more oscillatory, was desirable in that it made the final values of the system parameters independent of source of disturbance and also eliminated droop in these parameters. Definite improvement in system characteristics results from the use of proper compensation terms. At comparable gain points the compensated system is faster and more stable. Complete compensation eliminates engine interaction permitting each loop to be developed to an optimum point independently.

NACA TM 1386

REMARK ON THE THEORY OF LIFTING SURFACES. (Sulla teoria delle superfici portanti). Aldo Muggia. January 1956. 11p. diagrs. (NACA TM 1386. Trans. from Atti della Accademia delle Scienze di Torino, v. 87, 1952-1953)

First, the Weissinger method, as it applies to a rectangular wing, is discussed. By building on this framework it is shown how to treat the lift problem for any thin wing of arbitrary plan form.

NACA TN 3414

INFLUENCE OF TEMPERATURE ON CREEP, STRESS-RUPTURE, AND STATIC PROPERTIES OF MELAMINE-RESIN AND SILICONE-RESIN GLASS-FABRIC LAMINATES. William N. Findley, Harlan W. Peithman, and Will J. Worley, University of Illinois. January 1956. 71p. diagrs., photos., tabs. (NACA TN 3414)

Results are reported of static-tension, static-compression, tension-creep, and time-to-fracture tests of melamine-resin and silicone-resin glass-fabric laminates at temperatures up to 400° and 600° F, respectively. The mechanical properties of both laminates decreased with increase in temperature, as a rule. The creep data supply additional evidence that the percent increase in strain from one given time to another given time is independent of stress. An equation which describes the effect of stress, time, and temperature and is based on the activation-energy theory and a power function of time represents an analysis of the creep data.

NACA TN 3527

A SECOND-ORDER SHOCK-EXPANSION METHOD APPLICABLE TO BODIES OF REVOLUTION NEAR ZERO LIFT. Clarence A. Syvertson and David H. Dennis. January 1956. 57p. diagrs., tabs. (NACA TN 3527)

A second-order shock-expansion method applicable to bodies of revolution is developed by the use of the predictions of the generalized shock-expansion method in combination with characteristics theory. Equations defining the zero-lift pressure distributions and the normal-force and pitching-moment derivatives are derived. Comparisons with experimental results show that the method is applicable at values of the similarity parameter, the ratio of free-stream Mach number to nose fineness ratio, from about 0.4 to 2.

NACA TN 3554

A PRELIMINARY INVESTIGATION OF THE EFFECTS OF FREQUENCY AND AMPLITUDE ON THE ROLLING DERIVATIVES OF AN UNSWEPT-WING MODEL OSCILLATING IN ROLL. Lewis R. Fisher, Jacob H. Lichtenstein, and Katherine D. Williams. January 1956. 29p. diagrs., photos. (NACA TN 3554)

The low-speed yawing moment due to rolling and the damping-in-roll derivatives were obtained from forced oscillation-in-roll tests. These data are presented chiefly for an angle of attack of 0° for a complete model and its various components through a range of frequencies and amplitudes of the rolling oscillation. Comparisons between the oscillation results and steady-state results from conventional rolling-flow tests are made.

NACA TN 3589

DESIGN CRITERIA FOR AXISYMMETRIC AND TWO-DIMENSIONAL SUPERSONIC INLETS AND EXITS. James F. Connors and Rudolph C. Meyer. January 1956. 42p. diagrs., tabs. (NACA TN 3589)

Design charts for single- and double-oblique shock inlets and for a systematic family of isentropic axisymmetric and two-dimensional surfaces, suitable for either inlet or exit applications, are presented for Mach numbers up to 4.0. For isentropic inlets having a mass-flow ratio of unity and focused compression at the cowl-lip, compression limits based either on shock-structure or cowl-shock-attachment requirements are analyzed and evaluated. At Mach number 4.0, an all-external-compression isentropic inlet is limited to a theoretical total-pressure recovery of 0.685 based solely on shock losses.

NACA TN 3593

CLOUD-DROPLET INGESTION IN ENGINE INLETS WITH INLET VELOCITY RATIOS OF 1.0 AND 0.7. Rinaldo J. Brun. January 1956. 52p. diagrs., tab. (NACA TN 3593)

The paths of cloud droplets into two engine inlets are calculated. The amount of water in droplet form ingested by the inlets and the amount and distribution of water impinging on the inlet walls are obtained from these droplet-trajectory calculations. In both types of inlet a prolate ellipsoid of revolution (10 percent thick) represents either part or all of the forebody at the center of an annular inlet to an engine. The configurations can also represent a fuselage of an airplane with side ram-scoop inlets. The principal difference between the two inlets studied is that the inlet air velocity of one is 0.7 that of the other.

NACA TN 3596

ON THE PERMEABILITY OF POROUS MATERIALS. E. Carson Yates, Jr. January 1956. 31p. diagrs. (NACA TN 3596)

The effects on porous-material permeability characteristics of absolute pressure level (and associated scale effects), choking of the flow, bending the material, and other factors have been investigated. Samples of 30- by 250-mesh rolled Monel metal cloth and 1/16-inch-thick sintered bronze were calibrated with constant upstream pressures of 1 atmosphere and 2-1/3 atmospheres (varying downstream pressure) and with constant downstream pressure of 1 atmosphere (varying upstream pressure). Experiments showed permeability to be appreciably affected by absolute pressure level, flow choking, and thickness of the material. Moderate bending of the material caused no noticeable change in the permeability. Simple calculation and correlation procedures were developed for determining permeability with reasonable accuracy when experimental data are limited.

NACA TN 3598

METHOD AND TABLES FOR DETERMINING THE TIME RESPONSE TO A UNIT IMPULSE FROM FREQUENCY-RESPONSE DATA AND FOR DETERMINING THE FOURIER TRANSFORM OF A FUNCTION OF TIME. Carl R. Huss and James J. Donegan. January 1956. 38p. diagrs., tabs. (NACA TN 3598)

Methods are presented for rapidly determining the time response to a unit impulse from frequency-response data and for obtaining the Fourier transform of a function of time. Tables are presented which facilitate the necessary computations of the methods.

NACA TN 3600

CORRELATION OF CRIPPLING STRENGTH OF PLATE STRUCTURES WITH MATERIAL PROPERTIES. Roger A. Anderson and Melvin S. Anderson. January 1956. 50p. diagrs., tabs. (NACA TN 3600)

A correlation approach to the crippling-strength analysis of multiplate-element structures in new materials and at elevated temperatures is presented. Appropriately defined crippling-strength moduli and correlation procedures are given for predicting the effect of a change in material properties on the strength of a structure. The accuracy of the approach is illustrated with available experimental data obtained in various materials and under different temperature conditions.

NACA TN 3608

HYDRODYNAMIC IMPACT LOADS IN SMOOTH WATER FOR A PRISMATIC FLOAT HAVING AN ANGLE OF DEAD RISE OF 10°. Philip M. Edge, Jr. January 1956. 20p. diagrs., tab. (NACA TN 3608)

Hydrodynamic-loads data obtained at the Langley impact basin from tests of a prismatic float with an angle of dead rise of 10° are presented. Tests were made at fixed trims of 3°, 12°, 20°, and 30° and a range of flight-path angles from 2° to 23°. The data are presented as dimensionless coefficients and experimental values of dead-rise function and aspect-ratio factor are obtained.

NACA TN 3614

FLOW STUDIES ON DROOPED-LEADING-EDGE DELTA WINGS AT SUPERSONIC SPEED. William H. Michael, Jr. January 1956. 29p. diagrs., photos. (NACA TN 3614)

An experimental investigation of the flow over flat delta wings has been extended to include studies on delta wings with drooped leading edges. Vapor-screen, pressure-distribution, and ink-flow tests were made on a series of semispan delta wings with semiapex angles of 15°, 22.5°, and 31.75° and with 10 percent and 20 percent of the semispans drooped 15° in streamwise sections. The tests were made at a Mach number of 1.9.

NACA TN 3625

INVESTIGATION OF THE PROPULSIVE CHARACTERISTICS OF A HELICOPTER-TYPE PULSE-JET ENGINE OVER A RANGE OF MACH NUMBERS AND ANGLE OF YAW. Paul J. Carpenter, James P. Shivers, and Edwin E. Lee, Jr. January 1956. 24p. diagrs., photos. (NACA TN 3625)

The nonwhirling propulsive characteristics of a helicopter-type pulse-jet engine mounted on a simulated rotor blade have been determined in the Langley 16-foot transonic tunnel. A propulsive thrust of about 1 lb/sq in. of engine frontal area at Mach numbers from 0.25 to 0.45 was obtained. Propulsive thrust at Mach number 0.6 decreased to about 0.73 lb/sq in. frontal area. Yaw angles of 0° to 20° had no significant effect on engine thrust at Mach numbers below 0.5 and only small effects at higher speeds. Specific fuel consumption reached a minimum of 5.3 lb of fuel per hr per hp between Mach numbers of 0.4 and 0.5. Comparison of whirling and nonwhirling data indicates significant performance losses due to whirling above centrifugal accelerations of about 200g.

NACA TN 3652

EXPERIMENTAL INVESTIGATION OF AIR-FLOW UNIFORMITY AND PRESSURE LEVEL ON WIRE CLOTH FOR TRANSPIRATION-COOLING APPLICATIONS. Patrick L. Donoughe and Roy A. McKinnon. January 1956. 28p. diagrs., photos., tab. (NACA TN 3652. *Supersedes RM E52E16*)

An experimental investigation was conducted to obtain information on air-flow uniformity and pressure-level effects for various meshes of stainless-steel corduroy wire cloth, and permeability and strength data for a 20x200 mesh stainless-steel wire cloth. It was found that close control of the wire cloth thickness yielded sufficiently uniform air flow and that available methods may be used to predict the effect of pressure level. Permeability and strengths of the 20x200 mesh wire cloth were similar to those already available from other meshes. The reduced tensile strength of the 20x200 mesh wire cloth in the direction of the primary stresses is one and a half to three times as great as the strength of the best porous sintered materials presently available.

Aeronautical Research Council (Gt. Brit.)
THE SIMPLE HARMONIC MOTION OF A HELICOPTER ROTOR WITH HINGED BLADES. J. K. Zbrozek. 1955. 12p. diagrs. (ARC R & M 2813; ARC 12, 466. Supersedes RAE Aero 2319)

In simple harmonic oscillation of the helicopter with hinged blades, the tip path plane is tilted with respect to the shaft in the plane of oscillation and in the plane perpendicular to it. The angles of tilt are functions of angular velocity and acceleration. The influence of the acceleration term on the dynamic stability of the helicopter is small and depends mainly on the inertia number of the blade. The expressions for angles of tilt due to angular velocity can be simplified to the expressions obtained in previous work under assumptions of quasi-static conditions.

Aeronautical Research Council (Gt. Brit.)
A HIGH-SPEED CAMERA FOR THE PHOTOGRAPHY OF SHOCK-WAVE OSCILLATIONS IN A WIND TUNNEL. D. W. Holder, R. J. North, W. G. Standring, and J. S. T. Looms. 1955. 15p. diagrs., photos. (ARC R & M 2901; ARC 12,543)

A camera has been developed which enables oscillations of shock-waves and of other quasi-stationary phenomena in a wind tunnel to be photographed by either the schlieren method or the shadowgraph method at speeds up to 2000 frames per second, and with exposures of the order of 1 microsecond. Photographs of an oscillation which occurs when the critical Mach number is exceeded at low Reynolds number on an EC 1250 airfoil are included as examples.

Aeronautical Research Council (Gt. Brit.)
TESTS ON A TYPICAL WHITTLE COMPRESSOR. A. Simons and C. K. Roberts. 1955. 10p. diagrs. (ARC R & M 2913; ARC 15,145. Supersedes NGTE R. 121)

Tests have been carried out to determine the performance of a typical Whittle compressor (produced in 1944) as used in the W2/700 series of engines. At 1500 ft/sec tip speed the overall pressure ratio (total head) was 4.27 and the adiabatic efficiency was 75.6 percent at a mass flow of 36.3 lb/sec. The overall efficiency falls rapidly from 79.6 percent at 1400 ft/sec to 75.6 percent at 1500 ft/sec due to choking of the outer half of the impeller eye. The maximum diffuser efficiency is approximately 80 percent at a tip speed of 1500 ft/sec.

N-40734*

Aeronautical Research Council (Gt. Brit.)
MODEL TESTING TECHNIQUE EMPLOYED IN THE R. A. E. SEAPLANE TANK. T. B. Owen, A. G. Kurn, and A. G. Smith. 1955. 59p. diagrs., photos., tab. (ARC R & M 2976; ARC 16,464. Supersedes RAE Aero 2505)

A description is given of the various techniques evolved in recent years to provide model data as a basis for predicting the full-scale behavior of a seaplane. The seaplane tank and associated equipment are described in detail, together with the routine methods of operation. The factors affecting the choice of model scale are discussed and the methods of model construction described. A description is given of a typical test program on a new design to determine the longitudinal and lateral stability on the water, spray and rough water behavior, and water drag. The design factors affecting the longitudinal stability and spray formation are discussed in appendices.

RIGOROUS DETERMINATION OF PERMANENT WAVES OF FINITE AMPLITUDE. (Determination Rigoureuse des Ondes Permanentes D'ampleur Finie). T. Levi-Civita. December 1955. 73p. diagrs. (Trans. from Mathematische Annalen, v. 93, 1925, p. 264-314)

Details of concept and calculation are developed which permit a clear characterization of periodic irrotational permanent waves, that is, waves capable of being propagated without alteration of shape, at the surface of a liquid of infinite depth.

N-41218*

SHOCK WAVES IN A RELAXATION MEDIUM. (Udarnye volny v relaksiruyushchei srede). S. P. D'yakov. (1955). 9p. diagrs. (Trans. from Zhurnal Eksperimental'noi i Teoretisheskoi Fiziki, v. 27, no. 6, p. 728-734)

A general discussion of possible types of shock wave is attempted. In particular, the author asserts, without proof, the existence of a type of strong shock wave in which the pressure decreases as equilibrium is approached downstream from the initial compression shock. The major portion of the paper is concerned with an analytical discussion of weak shock waves in a medium in which relaxation processes can occur. No reference is made to pertinent American papers.

SHOCK WAVES IN AXIALLY SYMMETRIC SUPERSONIC JETS. Ryuma Kawamura. (1955). 19p. diagrs., photos. (Trans. from Tokyo University, Institute of Science and Technology, Reports, v. 6, no. 3, June 1952, p. 141-148)

A study is made of a jet of air issuing from a sonic orifice at low jet pressure ratios with special attention being devoted to the so-called triple point of the shock structure.

THEORY OF NONLINEAR SERVOMECHANISMS. (Théorie Des Servo-Mécanismes Non Linéaires). J. R. Dutilh. January 1956. 20p. diagrs. (Trans. from La Radio Francaise, May 1950, p. 1-7)

General aspects of servomechanisms; steady-state oscillation conditions for sustainment (servomechanisms with "on or off" operation without threshold, conditions for the sustainment of the oscillations, real linear servomechanisms, and relay servomechanisms with threshold); imperfection of the relays (hysteresis and delay introduced by relays); and improvement of the relay servomechanism are discussed. It is shown that nonlinear servomechanisms can be studied by means of methods very close to those which have been applied in the technique of linear servomechanisms.

DECLASSIFIED NACA RESEARCH REPORTS

This is authority for those possessing copies of the following research reports to declassify them from Confidential. Items marked (#) are UNAVAILABLE since they contain obsolete or proprietary information. Effective date of declassification January 11, 1956.

NACA RM A51A09

PRELIMINARY DATA ON THE EFFECT OF BODY-NOSE BLUNTNESS ON THE DRAG AND PRESSURE RECOVERY OF A SIDE-INLET-BODY COMBINATION AT MACH NUMBERS OF 1.4 AND 1.7. John F. Stroud and Warren E. Anderson. April 25, 1951. 13p. diagrs., photos. (NACA RM A51A09)

The pressure recovery, mass flow, and drag of a twin-scoop, side-inlet-body combination were measured at Mach numbers of 1.4 and 1.7. Tests were made with the original body and with three different nose shapes obtained by shortening the body and increasing the nose bluntness. The nose bluntness affected all the characteristics of the side-inlet-body combination, the major effect being a large increase in total external drag.

NACA RM A52A17

WIND-TUNNEL INVESTIGATION AT LOW SPEED OF A TWISTED AND CAMBERED WING SWEPT BACK 63° WITH VORTEX GENERATORS AND FENCES. James A. Weiberg and George B. McCullough. March 1952. 45p. diagrs., photos., 3 tabs. (NACA RM A52A17)

Force, pressure-distribution, and boundary-layer measurements at low speed showed that boundary-layer-control fences or vortex-generating devices can alleviate considerably the large variations in longitudinal stability with lift coefficient of a twisted and cambered 63° sweptback wing.

NACA RM A53A06

A FLIGHT COMPARISON OF A SUBMERGED INLET AND A SCOOP INLET AT TRANSONIC SPEEDS. L. Stewart Rolls. March 1953. 41p. diagrs., photo., tab. (NACA RM A53A06)

Flight tests were performed on a YF-93 airplane to evaluate the characteristics of a scoop inlet and a submerged divergent-wall inlet. The comparison between the two inlets was made on the basis of induction-system efficiency (ram-recovery ratio at the inlet and at the compressor, diffuser loss, and engine power output), the overall airplane drag coefficient, and computed factor of relative effectiveness. Although the tests indicated that the submerged inlet had higher drag coefficients and higher inlet recoveries than the scoop inlet, the overall performance with either configuration was about the same.

NACA RM A54A07

EFFECTS OF BASE BLEED ON THE BASE PRESSURE OF BLUNT-TRAILING-EDGE AIRFOILS AT SUPERSONIC SPEEDS. William R. Wimbrow. March 1954. 33p. diagrs., photos. (NACA RM A54A07)

The effect on base pressure of bleeding air to the semidead-air region at the trailing edge of two-dimensional blunt-trailing-edge airfoils has been investigated at Mach numbers of 1.5 and 2.0. The effects of varying the base-bleed rate, the cross-sectional area of the bleed nozzles, and the geometry of the nozzles were determined for two airfoil profiles with both laminar and turbulent boundary layers approaching the trailing edge. Reductions in base drag of the order of 50 percent were obtained.

NACA RM A54A22

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF A BODY-CONTOURING METHOD FOR ALLEVIATING THE ADVERSE INTERFERENCE AT THE ROOT OF A SWEPTBACK WING. John B. McDevitt and William M. Haire. April 1954. 38p. diagrs., photos. (NACA RM A54A22)

An experimental investigation was made of a body-contouring method for alleviating at subsonic speeds the adverse interference at the root of a 35° sweptback wing in combination with various bodies. Modifying the body shape did not significantly affect the aerodynamic characteristics at subcritical speeds. At Mach numbers above the critical, improved aerodynamic characteristics were evidenced by large reductions of drag, an increase in lift-curve slope, and a reduced change of pitching-moment-curve slope with increasing Mach number.

NACA RM A54H23

COMPARISON OF EXPERIMENTAL AND THEORETICAL NORMAL-FORCE DISTRIBUTIONS (INCLUDING REYNOLDS NUMBER EFFECTS) ON AN OGIVE-CYLINDER BODY AT MACH NUMBER 1.98. Edward W. Perkins and Leland H. Jorgensen. November 1954. 50p. diagrs., tab. (NACA RM A54H23)

Effects of Reynolds number and angle of attack on the pressure distribution and normal-force characteristics of a body of revolution consisting of a fineness ratio 3 ogival nose tangent to a cylindrical afterbody 7 diameters long have been determined. The test Mach number was 1.98 and the angle-of-attack range from 0° to 20°. The Reynolds numbers, based on body diameter, were 0.15×10^6 and 0.45×10^6. The experimental results are compared with theory.

NACA RM E8L10a
NACA RM E9A31

NACA RM E50F15

PRELIMINARY CORRELATION OF EFFICIENCY OF AIRCRAFT GAS-TURBINE COMBUSTORS FOR DIFFERENT OPERATING CONDITIONS. J. Howard Childs. September 21, 1950. 40p. diagrs., tab. (NACA RM E50F15)

An empirical correlation is presented of the combustion efficiency data previously obtained in experimental investigations with 14 aircraft gas-turbine combustors. A theoretical analysis of the combustion process is also presented. The theoretical analysis yields equations that predict the shape of the curves obtained by plotting the experimental data.

NACA RM E51A08

FLAME VELOCITIES OF FOUR ALKYLSILANES. Melvin Gerstein, Edgar L. Wong, and Oscar Levine. March 9, 1951. 14p. diagrs., tab. (NACA RM E51A08)

The rates of flame propagation of four alkylsilanes have been determined by a tube method. The maximum fundamental rate of flame propagation increases in the order tetramethylsilane < trimethylsilane < diethylsilane < monoethylsilane. The alkylsilanes have considerably higher flame velocities than the hydrocarbons that would result if the silicon were replaced by carbon, whereas the physical properties of the alkylsilanes resemble those of the corresponding hydrocarbons. When diethylsilane is blended with n-pentane, no marked increase in flame velocity occurs until the concentration of diethylsilane is greater than 20 percent.

NACA RM E51A26

PRELIMINARY INVESTIGATION OF EFFECTIVENESS OF BASE BLEED IN REDUCING DRAG OF BLUNT-BASE BODIES IN SUPERSONIC STREAM. Edgar M. Cortright, Jr., and Albert H. Schroeder. March 9, 1951. 23p. diagrs., photos. (NACA RM E51A26)

Experimental results are presented that evaluate the drag-reducing effectiveness of bleeding air to the base region of blunt-base bodies in a supersonic stream. Both pressure and force measurements on bodies of revolution at a Mach number of 1.91 are included. In the case of a body of revolution with cylindrical afterbody, reductions in base-pressure drag coefficient of 0.04 were obtained of which 0.03 was realized as a net gain when bleed air intake was obtained through holes in the afterbody.

NACA RM E51J18

EFFECT OF SPARK REPETITION RATE ON THE IGNITION LIMITS OF A SINGLE TUBULAR COMBUSTOR. Hampton H. Foster. December 1951. 12p. diagrs., tab. (NACA RM E51J18)

The effect of spark repetition rate on the altitude ignition limits of a single tubular (turbojet engine) combustor was investigated. An increase in sparking rate from 3 to 140 sparks per second reduced the ignition limiting combustor-inlet pressure about 2 to 4 inches of mercury for air-flow rates of 1.87 and 2.80 pounds per second per square foot. At 3.75 pounds per second per square foot, the corresponding reduction was about 4 to 12 inches of mercury. The trend was similar for both low- and high-volatility fuels and for two spark-energy levels.

NACA RM E52F13

EFFECT OF OXYGEN CONCENTRATION OF THE INLET OXYGEN-NITROGEN MIXTURE ON THE COMBUSTION EFFICIENCY OF A SINGLE J33 TURBOJET COMBUSTOR. Charles C. Graves. August 1952 45p. diagrs., 2 tabs. (NACA RM E52F13)

An investigation was conducted to determine the importance of molecular-scale processes in the overall turbojet combustion process. The effect of oxygen concentration of the inlet oxygen-nitrogen mixture on the combustion efficiency of a single J33 combustor was determined for a range of combustor-inlet pressures, and fuel-flow rates at constant combustor inlet temperature and weight-flow rate. Attempts were made to correlate combustion efficiency with selected fundamental combustion properties and with a simplified reaction-kinetics equation. At a given fuel-flow rate, combustion efficiency decreased at an increasing rate with reduction in oxygen concentration. For the pressures and oxygen concentrations tested, combustion efficiency decreased with a decrease in fuel-flow rate. At a given fuel-flow rate, combustion efficiency correlated with minimum spark-ignition energy, flame speed, and a simplified reaction-kinetics equation. A greater range of combustor-inlet conditions or other types of combustor test will be required to distinguish the most significant correlation.

NACA RM E53A27

EFFECT OF INLET OXYGEN CONCENTRATION ON COMBUSTION EFFICIENCY OF J33 SINGLE COMBUSTOR OPERATING WITH GASEOUS PROPANE. Charles C. Graves. March 1953. 22p. diagrs., tab. (NACA RM E53A27)

The effect of oxygen concentration of the inlet oxygen nitrogen mixture on the combustion efficiency of a J33 single combustor operating with propane was determined. Combustion efficiency data were obtained at combustor-inlet total pressures from 10.0 to 30.0 inches of mercury absolute, fuel flow rates from 0.008 to 0.016 pound per second, and inlet oxygen concentrations from 14 to 46 percent by volume. The combustor-inlet temperature and weight flow rate of the inlet oxygen-nitrogen mixture were held constant at 40° F and 1.0 pound per second, respectively. At a given fuel flow rate, combustion efficiency increased with oxygen concentration. The rate of increase was appreciably greater at the lower oxygen concentrations and combustion efficiencies. Change in fuel flow rate had a small effect on combustion efficiency over the major portion of the conditions investigated. At a given fuel flow rate, satisfactory correlations were obtained between combustion efficiency and parameters based on (a) a simplified reaction kinetics equation and (b) a flame speed mechanism. No satisfactory correlation was obtained between combustion efficiency and minimum spark ignition energy. In a previous investigation using liquid iso-octane fuel, satisfactory correlations were obtained with all parameters. Combustion efficiencies obtained with propane were appreciably higher than those obtained with iso-octane. However, the relative effects of inlet pressure and oxygen concentration on combustion efficiency were approximately the same for both fuels.

NACA RM E54G23

RELATION OF TURBINE-ENGINE COMBUSTION EFFICIENCY TO SECOND-ORDER REACTION KINETICS AND FUNDAMENTAL FLAME SPEED. J. Howard Childs and Charles C. Graves. August 1954. 37p. diagrs. (NACA RM E54G23)

Previous theoretical studies of the turbojet combustion process are summarized, and the resulting equations are applied to experimental data obtained from previous combustor tests. The parameter $P_i T_i / V_r$, based on the assumption that chemical reaction kinetics control combustion efficiency, provided adequate correlation of the combustion efficiency at low pressures. At higher operating pressures, the data were correlated better by the parameter $\frac{P_i^{1/3} T_i^{1.1}}{V_r}$, derived from the assumption that flame spreading controls combustion efficiency.

NACA RM L8A28c

EFFECTS OF SWEEP ON CONTROLS. John G. Lowry, John A. Axelson, and Harold I. Johnson. June 3, 1948. 29p diagrs. (NACA RM L8A28c)

An analysis of the principal results of recent control-surface research pertinent to transonic flight has been made. An indication of the nature of the changes in control-surface characteristics above the critical speed of the wing and a preliminary design procedure for estimating the effectiveness of flap-type controls on swept wings are presented.

NACA RM L9A04

NACA RM L9A18a

INVESTIGATION AT A MACH NUMBER OF 1.9 AND A REYNOLDS NUMBER OF 2.2 x 10^6 OF SEVERAL FLAP-TYPE LATERAL-CONTROL DEVICES ON A WING HAVING 42.7° SWEEPBACK OF THE LEADING EDGE. Kennith L. Goin. March 11, 1949. 28p. diagrs., photos., tabs. (NACA RM L9A18a)

Tests of a 42.7° sweptback wing with several aileron and nose-flap configurations were made in the Langley 9- by 12-inch supersonic blowdown tunnel at a Mach number of 1.90 and a Reynolds number of 2.2 x 10^6. The wing had an aspect ratio of 4, a taper ratio of 0.5, and an 8-percent-thick biconvex airfoil section in the streamwise direction. The changes in aileron configuration were made by varying the aileron contour, chord, and span and changes in nose-flap configurations were made by varying the span.

NACA RM L9L07

AERODYNAMIC CHARACTERISTICS AND FLYING QUALITIES OF A TAILLESS TRIANGULAR-WING AIRPLANE CONFIGURATION AS OBTAINED FROM FLIGHTS OF ROCKET-PROPELLED MODELS AT TRANSONIC AND LOW SUPERSONIC SPEEDS. Grady L. Mitcham, Joseph E. Stevens, and Harry P. Norris. February 9, 1950. 67p. diagrs., photos., tabs. (NACA RM L9L07)

A flight investigation of rocket-powered models of a tailless, triangular-wing airplane configuration was made at the NACA Pilotless Aircraft Research Station through the transonic and low supersonic speed range. An analysis of the aerodynamic coefficients, stability derivatives, and flying qualities based on the results obtained from the successful flight tests of three models is presented.

NACA RM L50A19

EFFECT OF WING-TANK LOCATION ON THE DRAG AND TRIM OF A SWEPT-WING MODEL AS MEASURED IN FLIGHT AT TRANSONIC SPEEDS. Clement J. Welsh and John D. Morrow. April 4, 1950. 18p. diagrs., photos. (NACA RM L50A19)

Results of an exploratory free-flight investigation at zero lift of several rocket-powered drag research models equipped with wing tanks are presented for a Mach number range from about 0.50 to 1.15. The tanks, which were slender bodies of revolution, were mounted on 34° sweptback, nontapered wings of 2.7 aspect ratio. The tanks were directly attached to the wings such that their center lines were positioned on and vertically displaced from the wing-chord plane for tip and inboard spanwise locations. The tanks positioned on the chord plane were also located more forward than were the vertically displaced tanks.

NACA RM L50A27

THE EFFECT OF SPANWISE AILERON LOCATION ON THE ROLLING EFFECTIVENESS OF WINGS WITH 0° AND 45° SWEEP AT SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS. H. Kurt Strass. April 25, 1950. 28p. diagrs., photo. (NACA RM L50A27)

An experimental free-flight investigation at subsonic, transonic, and supersonic speeds has been made of the rolling effectiveness of 0.2-chord plain faired inboard half-span, outer half-span, and full-span ailerons on wings employing the NACA 65A009 airfoil section at 0° and 45° sweepback. In addition a shielded horn balance was added to the outer half-span controls and the effect measured. Drag values were also obtained.

NACA RM L51A02

A TRANSONIC-WING INVESTIGATION IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL AT HIGH SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. WING-FUSELAGE CONFIGURATION HAVING A WING OF 0° SWEEPBACK, ASPECT RATIO 4.0, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. Maurice S. Cahn and Carroll R. Bryan. March 6, 1951. 37p. diagrs., photos. (NACA RM L51A02)

Force, moment, and wake characteristics were investigated at high subsonic Mach numbers and at a Mach number of 1.2 for a wing-fuselage configuration employing a wing with unswept quarter-chord line, aspect ratio 4, taper ratio 0.6, and an NACA 65A006 airfoil section.

NACA RM L51A11

SOME EXPERIMENTS ON THE FLUTTER OF SWEPTBACK CANTILEVER WING MODELS AT MACH NUMBER 1.3. W. J. Tuovila. March 15, 1951. 10p. diagrs., tab. (NACA RM L51A11)

Flutter tests of sweptback cantilever wing models have been made in a small intermittent two-dimensional supersonic tunnel where the testing technique involved changing the structural parameters so that the models would flutter at the tunnel design Mach number of 1.3. Data for 21 models covering sweep angles from 30° to 60° and with varying parameters are included. No attempt is made to correlate the data with analytical developments. However, reference values of flutter speed, obtained with a swept-wing flutter analysis based on two-dimensional incompressible flow, are compared with the experimental flutter speed in order to unify the results.

NACA RM L51A15

LARGE-SCALE FLIGHT MEASUREMENTS OF ZERO-LIFT DRAG AT MACH NUMBERS FROM 0.8 TO 1.6 OF A WING-BODY COMBINATION HAVING AN UNSWEPT 4.5-PERCENT-THICK WING WITH MODIFIED HEXAGONAL SECTIONS. Eugene D. Schult. March 23, 1951. 14p. diagrs., photos., tab. (NACA RM L51A15)

Measurements of zero-lift drag were made at high Reynolds numbers and from Mach numbers of 0.8 to 1.6 of a wing-body combination having a tapered, essentially unswept, 4.5-percent-thick wing of aspect ratio 3.04 mounted on a parabolic-arc body of fineness ratio 10.

NACA RM L51A29

FLIGHT INVESTIGATION AT MACH NUMBERS FROM 0.8 TO 1.5 OF THE DRAG OF A CANOPY LOCATED AT TWO POSITIONS ON A PARABOLIC BODY OF REVOLUTION. Clement J. Welsh and John D. Morrow. March 15, 1951. 15p. diagrs., photos., tabs. (NACA RM L51A29)

Results of an exploratory free-flight investigation of two rocket-powered drag research models equipped with canopies are presented for a Mach number range of 0.8 to 1.5. The models were different only in that one had the leading edge of its canopy located at the 15-percent fuselage station and the other had its canopy located at the 25-percent station. The drag of the two models was measured and compared with that of a model having no canopy.

NACA RM L51A30

NOTES ON LOW-LIFT BUFFETING AND WING DROPPING AT MACH NUMBERS NEAR 1. Paul E. Purser. March 16, 1951. 22p. diagrs., tab. (NACA RM L51A30)

A brief study of the available transonic Mach number data on low-lift buffeting and wing dropping is presented. Study indicates that there are combinations of airfoil-thickness ratio, aspect ratio, and sweep which may allow flight through the transonic speed range without experiencing buffet or wing drop at low lift.

NACA RM L52A07

PERFORMANCE OF AIR INLETS AT TRANSONIC AND LOW SUPERSONIC SPEEDS. Mark R. Nichols and Robert E. Pendley. February 1952. 22p. diagrs. (NACA RM L52A07)

A general discussion of the air-inlet problem is presented. Recently obtained drag and pressure-recovery data for transonic-type nose, scoop, and wing-root inlets are summarized. Preliminary results concerning the performance of the sharp-edged supersonic-type inlets at transonic and subsonic speeds also are given.

NACA RM L52A24

EXPERIMENTAL INVESTIGATION OF INTERNAL-FLOW CHARACTERISTICS OF FORWARD UNDERSLUNG FUSELAGE SCOOPS WITH UNSWEPT AND SWEPTBACK ENTRANCE AT MACH NUMBERS OF 1.41 TO 1.96. Robert W. Boswinkle, Jr., and Meade H. Mitchell, Jr. March 1952. 34p. photos., diagrs. (NACA RM L52A24)

Two versions of a type of forward underslung scoop mounted on a pointed fuselage were investigated principally at a Mach number of 1.41 in the Langley 9- by 12-inch supersonic blowdown tunnel. The scoop entrances were in the shape of a 60° sector of an annulus; the sides of one scoop were unswept and the sides of the other were sweptback. Total-pressure recoveries, surface-pressure distributions, and shadowgraphs were obtained over wide ranges of angle of attack and mass-flow ratio. A few tests at Mach numbers of 1.62 and 1.96 were also made. From a total-pressure-recovery standpoint the unswept scoop appears to be a satisfactory configuration at a Mach number of 1.41.

NACA RM L52A29

WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS IN PITCH OF WING-FUSELAGE COMBINATIONS AT HIGH SUBSONIC SPEEDS. ASPECT-RATIO SERIES. Richard E. Kuhn and James W. Wiggins. April 1952. 42p. diagrs., photos., tab. (NACA RM L52A29)

This paper presents the aerodynamic characteristics in pitch of wing-fuselage combinations with wings having a taper ratio of 0.6, sweep angle of 45° at the quarter-chord line, and aspect ratios of 2, 4, and 6. The tests covered a Mach number range from approximately 0.4 to 0.95 and an angle-of-attack range of -2° to 25°. The test Reynolds number varied from 1,500,000 to 6,000,000, depending upon the wing and Mach number. Fuselage-alone data also are included.

NACA RM L52A30

SOME FACTORS AFFECTING AUTOMATIC CONTROL OF AIRPLANES. Charles W. Mathews. February 1952. 15p. diagrs. (NACA RM L52A30)

Contains discussions of the determination of airplane transfer functions from measured responses to control transients, the factors affecting airplane transfer functions, and the implications of these factors with respect to autopilot design. Initial discussion is concerned with longitudinal control while later discussion is concerned with lateral and directional control.

NACA RM L53A13

INVESTIGATIONS OF THE DAMPING IN ROLL OF SWEPT AND TAPERED WINGS AT SUPERSONIC SPEEDS. Russell W. McDearmon and Harry S. Heinke, Jr. March 1953. 35p. diagrs., photos., tab. (NACA RM L53A13)

Damping-in-roll derivatives for a series of 33 swept and tapered wings have been obtained from supersonic wind-tunnel tests. The wings were mounted on a small cylindrical sting and tested at Mach numbers of 1.62, 1.93, and 2.41. Comparisons were made with the values of damping in roll from linear theory.

NACA RM L54A14

AERODYNAMIC CHARACTERISTICS OF A CIRCULAR CYLINDER AT MACH NUMBER 6.86 AND ANGLES OF ATTACK UP TO 90°. Jim A. Penland. March 1954. 30p. diagrs., photos. (NACA RM L54A14)

Pressure-distribution and force tests of a circular cylinder have been made in the Langley 11-inch hypersonic tunnel at a Mach number of 6.86, a Reynolds number of 129,000, and angles of attack up to 90°. The results are compared with the hypersonic approximation of Grimminger, Williams, and Young and a simple modification of the Newtonian flow theory. An evaluation of the crossflow theory is made through comparison of present results with available crossflow Mach number drag coefficients.

NACA RM L54A19

EXPERIMENTAL AND CALCULATED STATIC CHARACTERISTICS OF A TWO-BLADE NACA 10-(3)(062)-045 PROPELLER. John M. Swihart. March 1954. 20p. diagrs., photos., tab. (NACA RM L54A19)

This paper presents the static characteristics of a two-blade NACA 10-(3)(062)-045 propeller over a blade angle range from -5° to 40° measured at the 0.75 radial station at tip Mach numbers up to 1.0. Comparisons of experimental data with thrust and power coefficients calculated by strip theory show good agreement where adequate airfoil data are available. At any given blade angle the static thrust figure of merit increases with increasing tip Mach number for values of tip Mach number up to 1.0.

NACA RM L54A22

CHORDWISE PRESSURES AND SECTION FORCE AND MOMENT COEFFICIENTS AT HIGH SUBSONIC SPEEDS NEAR MIDSPAN OF A TAPERED 35° SWEPTBACK WING WITH A FLAP-TYPE CONTROL AND AN ATTACHED TAB. Alexander D. Hammond and Barbara M. Keffer. March 1954. 57p. diagrs., 35 tabs. (NACA RM L54A22)

This paper presents the effect of the deflection of a flap-type control with an attached tab on the chordwise pressures and on the section force and moment coefficients at the 46-percent-semispan station of a tapered 35° sweptback wing of aspect ratio 4 with an NACA 65A006 airfoil section. The tests were made at angles of attack from 0° to 20° and at Mach numbers from 0.60 to 0.93 for aileron deflections from -30° to 30° and tab deflections from -20° to 20°.

NACA RM L54A28a

THE FLOW PAST A STRAIGHT- AND A SWEPT-WING—BODY COMBINATION AND THEIR EQUIVALENT BODIES OF REVOLUTION AT MACH NUMBERS NEAR 1.0. Walter F. Lindsey. April 1954. 18p. diagrs., photos. (NACA RM L54A28a)

The complete flow fields past a straight and a swept wing-body combination and their equivalent bodies of revolution at Mach numbers around 1.0 have been observed by means of motion-picture schlieren photography. The results of these observations indicate that the shock growth and positions on the wing-body combinations are closely reproduced in the flow past their respective equivalent bodies.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1192

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF MUFFLERS WITH COMMENTS ON ENGINE-EXHAUST MUFFLER DESIGN. Don D. Davis, Jr., George M. Stokes, Dewey Moore, and George L. Stevens, Jr. 1954. iv, 47p. diagrs., photos., tabs. (NACA Rept. 1192. Supersedes TN 2893; TN 2943)

Equations are presented for the attenuation characteristics of several types of mufflers. Experimental curves of attenuation plotted against frequency are presented for 77 different mufflers with reflection-free tailpipe terminations and for four different mufflers with finite tailpipes. The results are compared with theory. The experiments were made at room temperature without flow; the sound source was a loud-speaker. The application of the theory to the design of engine-exhaust mufflers is discussed, and charts have been included for the assistance of the designer. Finally, the results of tests of four muffler-tailpipe combinations on a helicopter are presented.

NACA Rept. 1214

STATISTICAL MEASUREMENTS OF CONTACT CONDITIONS OF 478 TRANSPORT-AIRPLANE LANDINGS DURING ROUTINE DAYTIME OPERATIONS. Norman S. Silsby. 1955. ii, 17p. diagrs., photos., tabs. (NACA Rept. 1214. Supersedes TN 3194)

Statistical measurements have been obtained from photographs taken with a specially built motion-picture camera of 478 landings of present-day transport airplanes during routine daylight operations in clear air at the Washington National Airport. From these measurements, sinking speeds, bank angles, rolling velocities, and horizontal speeds have been evaluated and a limited statistical analysis of the results has been made. An attempt was made to determine the effect of various parameters such as gusty-wind conditions, wing loading, and size of airplane (number of engines) which influence the landing contact conditions.

NACA RM E55L14a

VISUAL STUDY OF FREE CONVECTION IN A NARROW VERTICAL ENCLOSURE. Ephraim M. Sparrow and Samuel J. Kaufman. February 1956. 14p. diagr., photos. (NACA RM E55L14a)

The free-convection flow of water in a narrow vertical enclosure, cooled at the top through a copper surface and open at the bottom to a heated reservoir, has been studied by means of a shadowgraph. It was found that there is no flow pattern which is steady with time, that is, no region of the enclosure is permanently a region of upflow or of downflow. Because of variations in the size of the various upflow and downflow regions arranged along the length of the enclosure at a given time, and because of changes with time, neither upflow nor downflow regions could be characterized by a definite size. The number of upflow and downflow regions varied with time.

NACA TM 1399

ACOUSTICS OF A NONHOMOGENEOUS MOVING MEDIUM. (Akustika Neodnorodnoi Dvizhushcheisya Sredy). D. I. Blokhintsev. February 1956. 194p. diagrs., photos. (NACA TM 1399. Trans. of Russian Book, 1946)

Theoretical basis of the acoustics of a moving nonhomogeneous medium is considered in this report. Experiments that illustrate or confirm some of the theoretical explanation or derivation of these acoustics are also included.

NACA TM 1415

LAMINAR FLOW ABOUT A ROTATING BODY OF REVOLUTION IN AN AXIAL AIRSTREAM. (Die laminare Strömung um einen axial angeströmten rotierreden Drehkörper). H. Schlichting. (Abstract of paper presented at the Eighth International Mechanics Congress, Istanbul, August 27, 1952). February 1956. 43p. diagrs., photo. (NACA TM 1415. Trans. from Ingenieur-Archiv, v. 21, no. 4, 1953, p. 227-244)

A method is given for calculating the incompressible laminar boundary layer on a rotating body of revolution at zero angle of attack in an airstream. The method is based on two boundary-layer momentum equations, one for the meridional direction and one for the circumferential direction. A simultaneous solution of both momentum equations yields the boundary-layer parameters, the friction drag, and the torque. The boundary-layer flow about a rotating sphere, about a body with a blunt base, and about two streamline bodies is calculated. The separation point is found to be affected by the spin.

NACA TN 3530

MINIMUM WAVE DRAG FOR ARBITRARY ARRANGEMENTS OF WINGS AND BODIES. Robert T. Jones. February 1956. 11p. diagrs. (NACA TN 3530)

Studies of various arrangements of wings and bodies designed to provide favorable wave interference at supersonic speeds lead to the problem of determining the minimum possible value of the wave resistance obtainable by any disposition of the elements of an aircraft within given dimensions defined by a region. Under the assumptions that the total lift and the total volume of the aircraft are given, conditions that must be satisfied if the drag is to be a minimum are found. For arbitrary regions the minimum value can be estimated by a simple formula giving a lower bound.

NACA TN 3564

EFFECT OF PNEUMATIC DE-ICERS AND ICE FORMATIONS ON AERODYNAMIC CHARACTERISTICS OF AN AIRFOIL. Dean T. Bowden. February 1956. 59p. diagrs., photos. (NACA TN 3564)

Measurements of drag, lift, and pitching moment of an NACA 0011 airfoil were made in icing conditions using pneumatic de-icers having either spanwise or chordwise inflatable tubes. Lift and drag penalties due to de-icer inflation and to ice remaining after de-icer inflation are presented. Inflation of the spanwise-tube de-icer caused a much greater increase in drag than inflation of the chordwise-tube de-icer. The two de-icers were equally effective in removing ice. Lift and drag penalties resulting from ice formed with the de-icer inoperative are also presented, as well as spoiler data for analyzing drag increases due to ice formations.

NACA TN 3594

EFFECT OF TRANSVERSE BODY FORCE ON CHANNEL FLOW WITH SMALL HEAT ADDITION. Simon Ostrach and Franklin K. Moore. February 1956. 31p. diagrs. (NACA TN 3594)

As a channel flow traverses a plane normal to the flow axis over which heat sources are uniformly distributed, analysis shows the flow to be displaced in the direction of the body force, becoming a shear flow far downstream. If heat sources are distributed nonuniformly, vortices are produced by the action of the body forces. The cases of small Mach number and, separately, large Froude number are considered. The flow in a rotor-tip combustor of a helicopter ram jet is considered as an example.

NACA TN 3595

WEAR OF TYPICAL CARBON-BASE SLIDING SEAL MATERIALS AT TEMPERATURES TO 700° F. Robert L. Johnson, Max A. Swikert, and John M. Bailey. February 1956. 22p. diagrs., photos., tab. (NACA TN 3595)

Wear and friction studies were made with carbon-type seal materials sliding against tool steel, stainless steel, and chromium-plated steel at temperatures to 700° F and a sliding velocity of 10,000 feet per minute. Wear was several times greater at 500° F and above than with no heat added for all carbon materials. The mating material had more effect on wear and surface failure than did the use of various impregnants in the carbon. Chromium plate gave less wear than the other mating materials under all conditions of the experiment.

NACA TN 3610

COMPARISON OF LANDING-IMPACT VELOCITIES OF FIRST AND SECOND WHEEL TO CONTACT FROM STATISTICAL MEASUREMENTS OF TRANSPORT AIRPLANE LANDINGS. Eziaslav N. Harrin. February 1956. 22p. diagrs., photo., tabs. (NACA TN 3610)

A statistical analysis of vertical velocities at second wheel to touch was made from motion pictures of 353 landings of transport-type airplanes at Washington National Airport. The effects of gusts, rolling direction, and number of engines are presented. Comparisons are made with vertical velocities of the first wheel to touch from NACA TN 3194.

NACA TN 3621

GUST-LOAD AND AIRSPEED DATA FROM ONE TYPE OF TWO-ENGINE AIRPLANE ON SIX CIVIL AIRLINE ROUTES FROM 1947 TO 1955. Walter G. Walker. February 1956. 25p. diagrs., tabs. (NACA TN 3621)

V-G data covering 70,000 hours were obtained from six different operations of a two-engine civil transport airplane and are analyzed to determine the severity and frequency of occurrence of the airspeeds, gust loads, and gusts. The results show sizable variations in the gusts, gust loads, and operating speeds among the present operations but, in general, these results are similar to those from past operations of the same type of airplane.

NACA TN 3651

CROSS FLOWS IN LAMINAR INCOMPRESSIBLE BOUNDARY LAYERS. Arthur G. Hansen and Howard Z. Herzig. February 1956. 50p. diagrs., photos., tabs. (NACA TN 3651)

An analysis is derived for the three-dimensional boundary-layer flow over a flat surface with a leading edge under main-flow streamlines which are translates and representable by polynomial expressions. The boundary layers are laminar and incompressible, and the profiles of their velocity components have similarity with respect to rectangular coordinates. Solutions are obtained for main-flow streamlines presentable by polynomials up to the 11th order. Flow-visualization experimental checks for the theory are provided for several flow configurations and for comparisons of the behavior of thick and thin boundary layers.

NACA TN 3658

IMPINGEMENT OF WATER DROPLETS ON A RECTANGULAR HALF BODY IN A TWO-DIMENSIONAL INCOMPRESSIBLE FLOW FIELD. William Lewis and Rinaldo J. Brun. February 1956. 27p. diagrs., tabs. (NACA TN 3658)

Trajectories of water droplets moving in the ideal two-dimensional flow field ahead of a body of rectangular cross section and infinite extent in the downstream direction have been calculated by means of a differential analyzer. Data on collection efficiency and distribtuion of water impingement are presented.

NACA TN 3666

BODIES OF REVOLUTION HAVING MINIMUM DRAG AT HIGH SUPERSONIC AIRSPEEDS. A. J. Eggers, Jr., Meyer M. Resnikoff, and David H. Dennis. February 1956. 38p. diagrs., photos. (NACA TN 3666. Supersedes RM A51K27; A52D24)

Newtonian impact theory is used to determine body shapes of minimum drag under various combinations of the conditions of given body length, base diameter, surface area, and volume. In addition an estimate is made of centrifugal forces, and their effect on the minimum-drag shapes is considered. An experimental investigation carried out in the Ames 10- by 14-inch supersonic wind tunnel on a family of bodies, including two of the minimum-drag shapes, is found to provide a substantiation of the analysis.

NACA TN 3667

WING-BODY COMBINATIONS WITH CERTAIN GEOMETRIC RESTRAINTS HAVING LOW ZERO-LIFT WAVE DRAG AT LOW SUPERSONIC MACH NUMBERS. Harvard Lomax. February 1956. 32p. diagrs. (NACA TN 3667)

Several variational problems involving optimum wing and body combinations having minimum wave drags for different kinds of geometrical restraints are analyzed. Particular attention is paid to the effect on the wave drag of shortening the fuselage and, for slender axially symmetric bodies, the effect of fixing the fuselage diameter at several points or even of fixing whole portions of its shape.

NACA RM A9B16

WIND-TUNNEL INVESTIGATION OF A TAILLESS TRIANGULAR-WING FIGHTER AIRCRAFT AT MACH NUMBERS FROM 0.5 TO 1.5. Leslie F. Lawrence and James L. Summers. June 24, 1949. 56p. diagrs., photos., tab. (NACA RM A9B16)

The aerodynamic characteristics of a tailless fighter aircraft employing a triangular wing of aspect ratio 2.31 are presented for Mach numbers from 0.5 to 1.52. The variation with Mach number of the static longitudinal stability, the drag, and the effectiveness of constant-chord control surfaces are determined for the airplane with an external compression type of air entry and an open nose type of air entry.

NACA RM A52A04

FLIGHT CALIBRATION OF ANGLE-OF-ATTACK AND SIDESLIP DETECTORS ON THE FUSELAGE OF A 35° SWEPT-WING FIGHTER AIRPLANE. Norman M. McFadden, George A. Rathert, Jr., and Richard S. Bray. February 1952. 26p. diagrs., photos. (NACA RM A52A04)

The position errors of angle-of-attack and sideslip detectors located on the fuselage of a 35° swept-wing fighter airplane were measured in flight over a Mach number range of 0.50 to 0.92 and at normal-force coefficients up to the buffet boundary. The angle of attack can be computed to ±0.2° on 90 percent of the data points using a linear equation in terms of indicated angle of attack and the ratio of impact pressure to static pressure. The variation of indicated angle of attack with sideslip was linear and small. Indicated sideslip varied linearly with true sideslip and was independent of Mach number.

NACA RM A52B20

THE EFFECTS OF REYNOLDS NUMBER AT MACH NUMBERS UP TO 0.94 ON THE LOADING ON A 35° SWEPTBACK WING HAVING NACA 65_1A012 STREAMWISE SECTIONS. Bruce E. Tinling and Armando E. Lopez. June 1952. 115p. diagrs., photos., tabs. (NACA RM A52B20)

Forces, moments, and surface-pressure data are presented for a range of Reynolds numbers from 2,000,000 to 10,000,000 at a Mach number of 0.25, and from 2,000,000 to approximately 4,500,000 at Mach numbers from 0.60 to 0.94. The surface pressures have been integrated to obtain section normal-force and pitching-moment coefficients for sections at 10, 20, 40, 60, 80, 90, and 95 percent of the semispan.

NACA RM A53A15

COMPARISON OF MEASURED AND PREDICTED INDICATED ANGLES OF ATTACK NEAR THE FUSELAGES OF A TRIANGULAR-WING WIND-TUNNEL MODEL AND A SWEPT-WING FIGHTER AIRPLANE IN FLIGHT. Norman M. McFadden, John L. McCloud, III, and Harry A. James. March 1953. 13p. diagrs. (NACA RM A53A15)

Comparisons are presented of predicted values of flow angles and those measured using detectors close to the surface of the forward portion of fuselages of a large-scale, triangular-wing, wind-tunnel model at low speeds and a 35° swept-wing fighter airplane in flight. Effects of flap deflection on the upwash of the triangular-wing model are included.

NACA RM A53B06

AN INVESTIGATION OF A FOUR-BLADE SINGLE-ROTATION PROPELLER IN COMBINATION WITH AN NACA 1-SERIES D-TYPE COWLING AT MACH NUMBERS UP TO 0.83. Robert M. Reynolds, Robert I. Sammonds, and George C. Kenyon. April 1953. 71p. diagrs., photos. (NACA RM A53B06)

Propeller thrust coefficients, power coefficients, efficiency, and pressures on the cowling surfaces were determined. Tests were conducted at Mach numbers from 0.20 to 0.83 for propeller blade angles of 40°, 50°, and 60°; for propeller advance-diameter ratios from 1.3 to 4.5; for cowling inlet-velocity ratios from 0.26 to 1.33; and for ideal and platform types of propeller-spinner junctures. All tests were made with the propeller-spinner-cowling combination at an angle of attack of 0° and at a Reynolds number of 1.5 million per foot.

NACA RM A54B18

THE TRANSONIC AERODYNAMIC CHARACTERISTICS OF STRUCTURALLY RELATED WINGS OF LOW ASPECT RATIO HAVING A SPANWISE VARIATION IN THICKNESS RATIO - TRANSONIC BUMP TECHNIQUE. Joseph W. Cleary. April 1954. 28p. diagrs., photo. (NACA RM A54B18)

Wings having aspect ratios of 4, 3, and 2 and equal plan-form taper and thickness-ratio taper were investigated to determine their transonic longitudinal characteristics and the effects of tapering thickness ratio. The wings were structurally related to give approximately the same bending stress for a given percent span and a given lift coefficient. The results are compared with data for other wings having the same plan form but constant thickness ratio.

NACA RM A54B18a

INVESTIGATION OF A THREE-BLADE PROPELLER IN COMBINATION WITH TWO DIFFERENT SPINNERS AND AN NACA D-TYPE COWL AT MACH NUMBERS UP TO 0.80. George C. Kenyon and Robert M. Reynolds. April 1954. 62p. diagrs., photos., tab. (NACA RM A54B18a)

This report presents the aerodynamic characteristics of a three-blade propeller (designated NACA 3.638-(675)(057)-0572) at Mach numbers up to 0.80. Tests were made at positive thrust for the propeller with a 1-series spinner and a modified conical spinner operating in the presence of an NACA 1-series D-type cowl. Tests were also conducted for the isolated propeller-spinner combination operating at positive thrust, negative thrust, and at near static conditions. Included are the results of airstream surveys of the local velocities in the plane of the propeller.

NACA RM A54B26

FLIGHT INVESTIGATION OF THE EFFECTS OF A PARTIAL-SPAN LEADING-EDGE CHORD EXTENSION OF THE AERODYNAMIC CHARACTERISTICS OF A 35° SWEPT-WING FIGHTER AIRPLANE. Frederick H. Matteson and Rudolph D. Van Dyke, Jr. April 1954. 34p. diagrs., photos., tabs. (NACA RM A54B26)

Flight measurements were made of the effects of a 15-percent-chord, partial-span, leading-edge extension on the longitudinal stability and drag of the F-86A airplane. Wing-fuselage pitching moments were determined from balancing tail load measurements, and complete airplane stability was determined from trim elevator angle measurements. Two fence configurations were tested in conjunction with the extended leading edge. Tuft studies and pilot opinions were obtained and compared with stability data.

NACA RM E8A30

THEORETICAL PERFORMANCE OF SOME ROCKET PROPELLANTS CONTAINING HYDROGEN, NITROGEN, AND OXYGEN. Riley O. Miller and Paul M. Ordin. May 26, 1948. 53p. diagrs., tabs. (NACA RM E8A30)

Theoretical performance data including nozzle-exit temperature, specific impulse, volume specific impulse and composition, temperature, and mean molecular weight of reaction products based on frozen equilibrium and isentropic expansion are presented for 13 propellant combinations at reaction pressure of 300 pounds per square inch absolute and expansion ratio of 20.4. On basis of maximum specific impulse alone, five fuels had the following order for any given oxidant: liquid hydrogen, hydrazine, liquid ammonia, and either hydrazine hydrate or hydroxylamine. Three oxidants with a given fuel had the following order: liquid ozone, liquid oxygen, and 100-percent hydrogen peroxide.

NACA RM E52A18

EFFECT OF INLET-AIR AND FUEL PARAMETERS ON SMOKING CHARACTERISTICS OF A SINGLE TUBULAR TURBOJET-ENGINE COMBUSTOR. Helmut F. Butze. April 1952. 26p. diagrs., photos., tabs. (NACA RM E52A18)

The effect of systematic variations in inlet-air and fuel parameters on the smoking characteristics of a single tubular turbojet-engine combustor was investigated. In addition a series of tests were conducted with a full-scale engine operating at static sea-level conditions over a range of engine speeds. In the single combustor increases in pressure effected large increases in smoke density while increases in velocity reduced smoke density. As fuel-air ratio was increased, smoke density increased, passed through a maximum, and finally decreased. Increases in fuel temperature increased smoke density slightly while inlet-air temperature and fuel volatility had little effect on smoke. In the full-scale engine smoke density increased with increasing engine speed and with decreasing exhaust-nozzle area.

NACA RM E54B05

EVALUATION OF A SILICONE-DIESTER LUBRICANT IN BENCH STUDIES AND IN A TURBOPROPELLER ENGINE. Robert L. Johnson, S. F. Murray, and Edmond E. Bisson. Appendix D: COPY OF REPORT BY SILICONE PRODUCTS DEPARTMENT OF GENERAL ELECTRIC ON NACA SD-17 FLUID. N. G. Holdstock, General Electric Company. May 1954. 32p. diagrs., photos., tabs. (NACA RM E54B05)

A silicone-diester blend (SD-17) was investigated in various bench studies and in a turbopropeller engine to determine its suitability as a lubricant for aircraft engines. The performance of the fluid was

satisfactory during more than 17 hours of operation in a T-38 engine with power levels from 1745 to 2400 horsepower. The fluid has better viscometric properties than currently used lubricants and could eliminate low-temperature starting and pumpability problems for turbopropeller engines. The fluid has good boundary lubrication and other lubricant properties as measured with most bench devices. Especially good gear lubrication characteristics were established in bench studies and in the engine test.

NACA RM H55A11

WING-LOAD MEASUREMENTS OF THE BELL X-5 RESEARCH AIRPLANE AT A SWEEP ANGLE OF 58.7°. Richard D. Banner, Robert D. Reed, and William L. Marcy. April 1955. 22p. diagrs., photo., tab. (NACA RM H55A11)

Flight measurements of the aerodynamic wing-panel loads have been made on the Bell X-5 research airplane from which the wing-panel normal-force-curve slope, the chordwise center of pressure, and the spanwise center of pressure have been determined from a Mach number of 0.61 to 0.97. A comparison of the loads calculated by theory was made at one Mach number.

NACA RM H55C07

FLIGHT DETERMINATION OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF THE BELL X-5 RESEARCH AIRPLANE AT 58.7° SWEEPBACK. Thomas W. Finch. May 1955. 30p. diagrs., photo., tab. (NACA RM H55C07)

Flight tests were performed with the Bell X-5 research airplane at 58.7° sweepback to measure the longitudinal stability and control characteristics from elevator and stabilizer maneuvers at 40,000 feet and elevator maneuvers at 25,000 feet and 15,000 feet. Results are presented for Mach numbers up to 1.0 and include trim characteristics, apparent stability parameters, relative control effectiveness, stick-force gradient, normal-force-curve slope, and effect of dynamic pressure and engine power. Comparison is made with wind-tunnel data.

NACA RM H55E20a

FLIGHT MEASUREMENTS OF HORIZONTAL-TAIL LOADS ON THE BELL X-5 RESEARCH AIRPLANE AT A SWEEP ANGLE OF 58.7°. Robert D. Reed. July 1955. 19p. diagrs., photo., tab. (NACA RM H55E20a)

Flight measurements of the horizontal tail loads on the Bell X-5 research airplane have been made in accelerated maneuvers at Mach numbers from 0.61 to 1.00 at an altitude of 40,000 feet. At this altitude the aerodynamic and balancing tail loads were determined at all normal-force coefficients up to near maximum lift. Comparisons were made with flight and wind-tunnel data obtained at 25,000 feet and 15,000 feet over a limited lift range.

NACA RM H55H10

FLIGHT MEASUREMENTS OF THE DYNAMIC LATERAL AND LONGITUDINAL STABILITY OF THE BELL X-5 RESEARCH AIRPLANE AT 58.7° SWEEPBACK. Edward N. Videan. October 1955. 68p. diagrs., photo., tabs. (NACA RM H55H10)

Longitudinal and lateral dynamic-response characteristics to elevator and rudder pulse deflections have been measured on the Bell X-5 research airplane at 58.7° sweepback. Flight records were obtained at altitudes of 40,000 feet and 25,000 feet. Period and damping, including nonlinear damping effects, are presented and comparison is made with U. S. military lateral dynamic stability criteria. Engine gyroscopic coupling effects are discussed and frequency-response calculations are presented.

NACA RM L9B11

EFFECTS OF HIGH-LIFT AND STALL-CONTROL DEVICES, FUSELAGE, AND HORIZONTAL TAIL ON A WING SWEPT BACK 42° AT THE LEADING EDGE AND HAVING SYMMETRICAL CIRCULAR-ARC AIRFOIL SECTIONS AT A REYNOLDS NUMBER OF 6.9×10^6. Robert L. Woods and Stanley H. Spooner. April 20, 1949. 42p. diagrs., photos., tabs. (NACA RM L9B11)

The effects of high-lift and stall-control devices and fuselage and horizontal tail vertical positions on a wing swept back 42° at the leading edge and having symmetrical circular-arc airfoil sections are presented. The devices included drooped-nose flaps, extensible leading-edge flaps, split flaps, and upper-surface fences. The Reynolds number and Mach number of the investigation were 6.9×10^6 and 0.15, respectively.

NACA RM L50B08

FREE-FLIGHT INVESTIGATION AT TRANSONIC AND SUPERSONIC SPEEDS OF THE ROLLING EFFECTIVENESS OF A PARTIAL-SPAN AILERON ON AN INVERSELY TAPERED SWEPTBACK WING. H. Kurt Strass, E. M. Fields, and E. D. Schult. May 1, 1950. 17p. diagrs., photo., tabs. (NACA RM L50B08)

The rolling effectiveness of an inversely tapered sweptback wing having a 10-percent-thick cambered airfoil section and outboard partial-span controls has been measured in free flight by means of rocket-propelled test vehicles.

NACA RM L50B14

AN NACA TRANSONIC TEST SECTION WITH TAPERED SLOTS TESTED AT MACH NUMBERS TO 1.26. Vernon G. Ward, Charles F. Whitcomb, and Merwin D. Pearson. March 30, 1950. 19p. diagrs., photos., tab. (NACA RM L50B14)

Satisfactorily uniform and continuously variable supersonic flows up to a Mach number of 1.26 have been attained in an NACA transonic test section employing pointed 1-1/2 jet-diameter linear-divergent slots. The favorable characteristics of reduction of interference due to solid blockage and the elimination of choking are obtainable in this configuration on a relatively large nonlifting body of revolution through the Mach number range up to 1.08.

NACA RM L51B16

WIND-TUNNEL INVESTIGATION AT SUBSONIC AND LOW TRANSONIC SPEEDS OF THE EFFECTS OF AILERON SPAN AND SPANWISE LOCATION ON THE ROLLING CHARACTERISTICS OF A TEST VEHICLE WITH THREE UNTAPERED 45° SWEPTBACK WINGS. Harold S. Johnson. April 6, 1951. 26p. diagrs., photo., tab. (NACA RM L51B16)

A wind-tunnel investigation through a 0.30 to 0.94 Mach number range was made to determine the rolling characteristics of a free-flight rocket-propelled type of test vehicle having untapered 45° sweptback wings of aspect ratio 3.7 equipped with 0.20-chord ailerons having various spans and spanwise locations. The data are compared to theory and also to results obtained by other testing techniques.

NACA RM L51C16

INVESTIGATION OF THE EFFECTS OF TWIST AND CAMBER ON THE AERODYNAMIC CHARACTERISTICS OF A 50° 38' SWEPTBACK WING OF ASPECT RATIO 2.98. TRANSONIC-BUMP METHOD. Kenneth P. Spreemann and William J. Alford, Jr. August 1951. 33p. diagrs., photos., tab. (NACA RM L51C16)

An investigation of two semispan wings swept back 50° 38' was conducted in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.68 to 1.15 by use of the transonic-bump technique. This paper presents the results of the investigation of wing-alone and wing-fuselage configurations of the two wings; one was an untwisted uncambered wing and the other was the same wing but incorporated twist and camber designed to give uniform load at a lift coefficient of 0.25 at a Mach number of 1.10. The semispan wings had their quarter-chord lines swept back 50° 38', aspect ratios 2.98, taper ratios 0 45, and modified NACA 64A-series airfoil sections tapered in thickness. Lift, pitching moment, drag, and bending moment were obtained for these configurations.

NACA RM L51E02a

REVIEW OF SOME RECENT DATA ON BUFFET BOUNDARIES. Paul E. Purser and John A. Wyss. May 23, 1951. 11p. diagrs. (NACA RM L51E02a)

A study has been made of a large amount of data pertaining to high-speed buffet boundaries of various airplane configurations. The data indicate a strong influence of wing configuration on buffet boundaries. Based on the comparisons available, reasonably accurate estimates of the buffet boundary can probably be made for unswept wings with thickness ratios above 8 to 10 percent. Accurate estimates cannot yet be made for swept wings. Decreases in aspect ratio and thickness ratio and increases in sweepback tend to alleviate high-speed buffeting.

NACA RM L52B01

AN APPROXIMATION TO THE EFFECT OF GEOMETRIC DIHEDRAL ON THE ROLLING MOMENT DUE TO SIDESLIP FOR WINGS AT TRANSONIC AND SUPERSONIC SPEEDS. Paul E. Purser. April 1952. 10p. diagrs. (NACA RM L52B01)

A simple geometric relation is proposed by which the effect of geometric dihedral on the rolling moment due to sideslip at transonic and supersonic speeds may be estimated for wings if either the damping in roll or the rolling moment due to differential wing incidence is known.

NACA RM L52B12

TRANSONIC DRAG CHARACTERISTICS AND PRESSURE DISTRIBUTION ON THE BODY OF A WING-BODY COMBINATION CONSISTING OF A BODY OF REVOLUTION OF FINENESS RATIO 12 AND A WING HAVING SWEEPBACK OF 45°, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTIONS. Max C. Kurbjun and Jim Rogers Thompson. April 1952. 28p. diagrs., photo., tabs. (NACA RM L52B12)

The drag and body pressure distribution were measured near zero lift for a representative wing-body combination at Mach numbers between 0.75 and 1.16 by the free-fall method. Analysis showed that the mechanism of the drag rise was similar to that for a body without wings except that the drag rise occurred at a lower Mach number because of the lower critical Mach number of the combination. The results were in generally satisfactory agreement with results for similar configurations obtained by different test techniques. An unfavorable interference effect on the body drag due to the presence of the wing occurred at transonic speeds.

NACA RM L52B14a

A PRELIMINARY WIND-TUNNEL INVESTIGATION OF FLUTTER CHARACTERISTICS OF DELTA WINGS. Robert W. Herr. April 1952. 35p. diagrs., tabs. (NACA RM L52B14a)

Results of 90 experimental wind-tunnel flutter tests performed on three delta-wing models are presented. The tests covered a range of tunnel pressures corresponding to altitudes from sea level to 78,000 feet. The natural vibration modes of these models were found experimentally by using a photographic technique.

NACA RM L52B15

LOW-SPEED LATERAL-CONTROL CHARACTERISTICS OF AN UNSWEPT WING WITH HEXAGONAL AIRFOIL SECTIONS AND ASPECT RATIO 2.5 EQUIPPED WITH SPOILERS AND WITH SHARP- AND THICKENED-TRAILING-EDGE FLAP-TYPE AILERONS AT A REYNOLDS NUMBER OF 7.6×10^6 James E. Fitzpatrick and Robert L. Woods. April 1952. 58p. photos., diagrs., tab. (NACA RM L52B15)

The lateral-control characteristics of two spans of spoilers and sharp- and thickened-trailing-edge ailerons on an unswept wing of aspect ratio 2.5 and hexagonal airfoil sections are presented. The tests were conducted at a Reynolds number of 7.6×10^6 and a Mach number of 0.15 and included measurements of rolling moments, yawing moments, aileron hinge moments, normal forces, and balance-chamber pressures for various configurations of wing and fuselage, droop-nose flap, and plain flaps. Measurements of the instantaneous pressure differential at several points on the aileron were also made.

NACA RM L52G14

PRELIMINARY RESULTS OF HORIZONTAL-TAIL LOAD MEASUREMENTS OF THE BELL X-5 RESEARCH AIRPLANE. John T. Rogers and Angel H. Dunn. August 15, 1952. 22p. diagrs., photos., tabs. (NACA RM L52G14)

Horizontal-tail load measurements were made during the Bell acceptance tests of a transonic speed research airplane having wings variable in flight between 20° and 60° sweepback. Load measurements were made during sweep changes in level flight from Mach numbers of 0.5 to 0.85, and during pull-ups at a Mach number of 0.83 at sweep angles of 20°, 45°, and 59°.

NACA RM L52K13b

FLIGHT MEASUREMENTS OF THE STABILITY CHARACTERISTICS OF THE BELL X-5 RESEARCH AIRPLANE IN SIDESLIPS AT 59° SWEEPBACK. Joan M. Childs. February 1953. 23p. diagrs., photos., tab. (NACA RM L52K13b)

Flight measurements of the stability characteristics of the Bell X-5 research airplane were made in steady sideslips at 59° sweepback at Mach numbers from 0.62 to 0.97 at altitudes varying from 35,000 to 40,000 feet.

NACA RM L52K18b

PRELIMINARY RESULTS OF STABILITY AND CONTROL INVESTIGATION OF THE BELL X-5 RESEARCH AIRPLANE. Thomas W. Finch and Donald W. Briggs. February 1953. 35p. diagrs., photos., tabs. (NACA RM L52K18b)

Results obtained during the acceptance tests of the X-5 airplane are presented. Information on the stalling characteristics, static longitudinal stability characteristics, and lateral control characteristics at various sweep angles is included.

NACA RM L53A09b

FLIGHT DETERMINATION OF THE STATIC LONGITUDINAL STABILITY BOUNDARIES OF THE BELL X-5 RESEARCH AIRPLANE WITH 59° SWEEPBACK. Thomas W. Finch and Joseph A. Walker. February 1953. 51p. diagrs., photo., tab. (NACA RM L53A09b)

Results obtained during flights of the Bell X-5 airplane with 59° sweepback are presented showing the variation with Mach number of the normal-force coefficient at the longitudinal reduction in stability. Results are given for a Mach number range of 0.67 to 0.98.

NACA RM L53A09c

LIFT AND DRAG CHARACTERISTICS OF THE BELL X-5 RESEARCH AIRPLANE AT 59° SWEEPBACK FOR MACH NUMBERS FROM 0.60 TO 1.03. Donald R. Bellman. February 1953. 37p. diagrs., photos., tab. (NACA RM L53A09c)

Lift and drag coefficients for the 59° sweptback configuration of the Bell X-5 airplane were determined from flight tests covering the Mach number range 0.60 to 1.03. A brief comparison is made between the 20° and 59° sweptback configuration.

NACA RM L53B17

THE EFFECT OF BLADE-SECTION CAMBER ON THE STALL-FLUTTER CHARACTERISTICS OF THREE NACA PROPELLERS AT ZERO ADVANCE. Arthur E. Allis and John M. Swihart. April 1953. 29p. diagrs., photo., tab. (NACA RM L53B17)

Stall-flutter characteristics of three 10-foot-diameter, two-blade propellers have been determined at zero advance for blade angles from 16° to 38° at the Langley propeller static test stand. The blades differed only in design lift coefficient, having constant radial values of 0, 0.3, and 0.5. The results indicate that an increase in design lift coefficient gave an increase in flutter-speed coefficient and thrust coefficient for practical propeller operating conditions.

NACA RM L53B26

LOW-SPEED AILERON EFFECTIVENESS AS DETERMINED BY FORCE TESTS AND VISUAL-FLOW OBSERVATIONS ON A 52° SWEPTBACK WING WITH AND WITHOUT CHORD-EXTENSIONS. Patrick A. Cancro. April 1953. 38p. diagrs., photos. (NACA RM L53B26)

The results of an investigation of the effects of leading-edge chord-extensions and extensible leading-edge flaps on the low-speed aileron characteristics of a 52° sweptback wing with circular-arc airfoil sections are presented. A description and illustrations of the vortex flow as it passes over the wing are included. The investigation was conducted at Reynolds numbers of 5.5×10^6 and 1.3×10^6 and corresponding Mach numbers of 0.11 and 0.065 for an angle-of-attack range of 0° through stall.

NACA RM L53E28

LONGITUDINAL FLIGHT CHARACTERISTICS OF THE BELL X-5 RESEARCH AIRPLANE AT 59° SWEEPBACK WITH MODIFIED WING ROOTS. James A. Martin. August 1953. 25p. diagrs., photos., tab. (NACA RM L53E28)

In an attempt to improve the longitudinal stability characteristics of the Bell X-5 research airplane at 59° sweepback the wing-root leading edge was modified, the original 52.5° sweptback leading-edge fillets being replaced by rounded leading-edge fillets. The two fillet configurations are compared in this paper on the basis of results obtained from maneuvers into the region of reduced stability at pressure altitudes from 28,000 to 40,000 feet and in the Mach number range from that for stall approach in the clean condition to a Mach number of 0.97.

NACA RM L53J01b

SOME DESIGN CONSIDERATIONS PERTINENT TO THE ROUGH-AIR BEHAVIOR OF AIRPLANES AT LOW ALTITUDE. Philip Donely and Clarence L. Gillis. November 1953. 21p. diagrs., tabs. (NACA RM L53J01b)

For high-speed low-altitude flight of 1 or 2 hours duration, study indicates that the airplane motions and accelerations due to rough air should be reduced to 30 percent of current levels. This reduction can be obtained by increasing the wing loading or reducing the lift-curve slope. For some configurations, artificial damping is beneficial.

NACA RM L54A11

DISTRIBUTION OF LIFT AND PITCHING MOMENT BETWEEN WING AND FUSELAGE AND EFFECTS OF WING FLEXIBILITY AND DIVE BRAKE ON A 1/30-SCALE SEMISPAN MODEL OF THE BELL X-5 AIRPLANE AT TRANSONIC SPEEDS AS DETERMINED BY THE NACA WING-FLOW METHOD. Garland J. Morris and Norman S. Silsby. March 1954. 46p. diagrs., photos., tab. (NACA RM L54A11)

An investigation was made at transonic speeds by the NACA wing-flow method to determine the interaction effects between the wing and fuselage, the effects of wing flexibility, and the effect of the addition of a dive brake on a 1/30-scale semispan model of the Bell X-5 airplane. Lift, pitching moments, and wing bending moments were obtained at various angles of attack for the 60°, 40°, and 20° sweptback duralumin wings in the presence of, but detached from, the fuselage. In addition, lift, drag, and pitching moments were obtained for the complete wing-body-tail configuration with a 60° sweptback wood wing and with a fuselage dive brake on the model with the 60° duralumin wing to determine the separate effects of flexibility and dive brake on the longitudinal stability characteristics. The Reynolds number was of the order of 1.0×10^6.

NACA RM L54B08

HINGE-MOMENT, LIFT, AND PITCHING-MOMENT CHARACTERISTICS OF A FLAP-TYPE CONTROL SURFACE HAVING VARIOUS HINGE-LINE LOCATIONS ON A 4-PERCENT-THICK 60° DELTA WING. TRANSONIC-BUMP METHOD. Robert F. Thompson. March 1954. 73p. diagrs., photo. (NACA RM L54B08)

Lift, pitching-moment, and flap hinge-moment coefficients were obtained for a 4-percent-thick 60° delta wing equipped with a flap-type control surface having various hinge-line locations. The trailing-edge control spanned the inboard 66 percent of the wing semispan and ratios of balance chord to flap chord tested were 0.07, 0.32, 0.50, 0.79, and 1.03. The investigation was made through an angle-of-attack range of -6° to 15°, a Mach number range from 0.60 to 1.18, and a flap-deflection range of approximately $\pm 30^{\circ}$.

NACA RM L54B15a

AN EXPERIMENTAL INVESTIGATION OF THE TRANSONIC-FLOW-GENERATION AND SHOCK-WAVE-REFLECTION CHARACTERISTICS OF A TWO-DIMENSIONAL WIND TUNNEL WITH 17-PERCENT-OPEN PERFORATED WALLS. Don D. Davis, Jr., Thomas B. Sellers, and George M. Stokes. April 1954. 40p. diagrs., photos. (NACA RM L54B15a)

The results of tests to determine the transonic-flow-generation and shock-wave-reflection characteristics of a wind tunnel with 17-percent-open perforated walls are presented. The wave-reflection tests were made at a free-stream Mach number of 1.28 with the perforated walls diverged 10', 15', 20', 25', and 30'. In conjunction with the wave-reflection tests, boundary-layer measurements were made with and without the model in the tunnel. Suction mass flow and perforated wall boundary-layer measurements were made at a Mach number of 0.98 over a range of divergence angles from -15' to 30'. Equations are derived which relate the suction flow to the perforated-wall boundary layer and friction coefficient.

NACA RM L54B18a

SUBSONIC INVESTIGATION OF EFFECTS OF BODY INDENTATION ON ZERO-LIFT DRAG CHARACTERISTICS OF A 45° SWEPTBACK WING-BODY COMBINATION WITH NATURAL AND FIXED BOUNDARY-LAYER TRANSITION THROUGH A RANGE OF REYNOLDS NUMBER FROM 1×10^6 TO 8×10^6. Gene J. Bingham and Albert L. Braslow. April 1954. 10p. diagrs., photos. (NACA RM L54B18a)

An investigation has been conducted in the Langley low-turbulence pressure tunnel to study the effects of body indentation according to the transonic area rule on the subcritical zero-lift drag coefficient of a 45° sweptback wing-body combination having an aspect ratio 4, taper-ratio-0.3 wing, with NACA 65A006 airfoil sections. The tests included studies of a basic and an indented body with natural transition and with fixed transition near the wing leading edge through a Reynolds number range from 1.0×10^6 to 7.6×10^6. A fluorescent lacquer technique was also used as a visual aid for comparison of the transition positions on the basic and indented configurations. The data obtained in the present investigation have been compared with British studies of the effects of sweepback on laminar boundary-layer stability.

NACA RM L54B22

MEASUREMENTS OF NORMAL-FORCE-COEFFICIENT FLUCTUATION ON FOUR 9-PERCENT-THICK AIRFOILS HAVING DIFFERENT LOCATIONS OF MAXIMUM THICKNESS. Milton D. Humphreys. April 1954. 21p. diagrs., photos. (NACA RM L54B22)

The effects of the location of maximum thickness on pressure pulsations and root-mean-square normal-force-coefficient fluctuations on 9-percent-thick airfoils have been obtained at transonic speeds, and typical flow conditions were recorded by schlieren motion pictures. The results indicated that at all Mach numbers, for normal-force coefficients up to 0.6, the section had little effect on the pressure pulsations and root-mean-square normal-force fluctuations. At normal-force coefficients above 0.6, up to approximately the maximum normal-force coefficient, considerable reductions in force fluctuations were obtained by using an airfoil having the maximum thickness located at or behind the 42.5-percent-chord station. From the standpoint of local panel loads, none of the airfoils had consistently lower loads throughout the speed and normal-force-coefficient ranges. It appears, however, that the NACA 65A009 airfoil would probably be the best choice of the sections tested for operation throughout the high subsonic Mach number range.

NACA RM L54B24a

THEORETICAL INVESTIGATION OF SOME DISCONTINUOUS YAW DAMPERS. William H. Phillips and Helmut A. Kuehnel. April 1954. 39p. diagrs. (NACA RM L54B24a)

A theoretical investigation of some discontinuous yaw dampers is made utilizing a modified phase-plane method of analysis. Four methods of operating a discontinuous control are considered and the damping and hunting tendencies are compared. Application of the theoretical results to a given set of conditions is illustrated and changes in airspeed as they affect the damping and hunting tendencies are considered.

NACA RM L54B25

EFFECTS OF SWEEP AND THICKNESS ON THE STATIC LONGITUDINAL AERODYNAMIC CHARACTERISTICS OF A SERIES OF THIN, LOW-ASPECT-RATIO, HIGHLY TAPERED WINGS AT TRANSONIC SPEEDS. TRANSONIC-BUMP METHOD. Albert G. Few, Jr., and Paul G. Fournier. April 1954. 107p. diagrs., photo., tab. (NACA RM L54B25)

The present paper presents results of the transonic static longitudinal aerodynamic characteristics of a series of thin, low-aspect-ratio, highly tapered wings. The tests covered a Mach number range from about 0.60 to 1.18 employing the transonic-bump technique. Reynolds number ranged from about 0.75×10^6 to 0.95×10^6, and angles of attack from -10° to approximately 32°.

NACA RM L54C17

FLIGHT DETERMINATION OF THE BUFFETING CHARACTERISTICS OF THE BELL X-5 RESEARCH AIRPLANE AT 58.7° SWEEPBACK. Donald W. Briggs. May 1954. 31p. diagrs., photo., tabs. (NACA RM L54C17)

Measurements have been made of wing and tail buffet intensities experienced by the Bell X-5 research airplane at 58.7° sweepback. Results are given for a Mach number range from 0.65 to approximately 1.03.

NACA RM L54F30

METHODS FOR OBTAINING DESIRED HELICOPTER STABILITY CHARACTERISTICS. F. B. Gustafson and Robert J. Tapscott. August 1954. 12p. tabs. (NACA RM L54F30)

A brief summary is made of methods available to the helicopter designer for obtaining desired stability characteristics by modifications to the airframe design. The discussion is based on modifications made during the establishment of flying-qualities criteria and includes sample indications of theoretical studies of additional methods.

NACA RM L54G05

METHODS OF PREDICTING HELICOPTER STABILITY. Robert J. Tapscott and F. B. Gustafson. November 1954. 15p. diagrs. (NACA RM L54G05)

Some of the methods of predicting rotor stability derivatives have been reviewed. The methods by which these rotor derivatives are employed to estimate helicopter stability characteristics have been summarized. It is concluded that, although these methods are not always feasible for predicting absolute values of the stability of the helicopter, the effects on stability of changes in individual derivatives can generally be estimated satisfactorily.

NACA RM L55J27

PRELIMINARY INVESTIGATION OF SELF-EXCITED VIBRATIONS OF SINGLE PLANING SURFACES. Elmo J. Mottard. January 1956. 19p. diagrs., photos., tab. (NACA RM L55J27)

The effect of various planing-surface shapes, conditions of restraint, loads, trims, and speeds on the occurrence of self-excited vibrations was sought. It was found that vibration occurs with high aspect ratio (order of 10) of the wetted portion with freedom in rise. It may occur without freedom in trim. Limiting the aspect ratio (by the use of dead rise or a pointed trailing edge, for example) tends to reduce or eliminate the vibrations. Data are presented for the range of variables likely to be encountered with airplane hydro-skis.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1211

EXPERIMENTAL INVESTIGATION OF FREE-CONVECTION HEAT TRANSFER IN VERTICAL TUBE AT LARGE GRASHOF NUMBERS. E. R. G. Eckert and A. J. Diaguila. 1955. ii, 14p. diagrs., photos., tab. (NACA Rept. 1211. Supersedes RM E52F30)

Local free-convection heat-transfer coefficients and temperature fields in the turbulent flow range were obtained within a vertical, stationary tube closed at the bottom, heated along its walls, and having a length-to-diameter ratio of 5. Convective heat-transfer coefficients were correlated by the general relations for free-convection heat transfer. These coefficients, converted to dimensionless Nusselt numbers were 35 percent below known relations for vertical flat plates. Air temperature measurements within the tube indicated a thin boundary layer along the heated wall surface and unstable conditions in the air flow.

NACA Rept. 1216

CHARTS FOR ESTIMATING TAIL-ROTOR CONTRIBUTION TO HELICOPTER DIRECTIONAL STABILITY AND CONTROL IN LOW-SPEED FLIGHT. Kenneth B. Amer and Alfred Gessow. 1955. ii, 22p. diagrs., photo., tabs. (NACA Rept. 1216. Supersedes TN 3156)

Theoretically derived charts and equations are presented by which tail-rotor design studies of directional trim and control response at low forward speed can be conveniently made. Comparisons between theoretical and experimental results are presented. The charts indicate and flight tests confirm that, under certain flight conditions, a region of vortex roughness is encountered by the tail rotor, making prolonged operation difficult in this region. The charts can also be used to obtain the main-rotor stability derivatives of thrust with respect to collective pitch and angle of attack at low forward speeds.

NACA Rept. 1217

THEORETICAL PREDICTION OF PRESSURE DISTRIBUTIONS ON NONLIFTING AIRFOILS AT HIGH SUBSONIC SPEEDS. John R. Spreiter and Alberta Alksne. 1955. iii, 42p. diagrs., photos. (NACA Rept. 1217. Supersedes TN 3096)

Theoretical pressure distributions on nonlifting circular-arc airfoils in flows with high subsonic free-stream velocity are found by determining approximate solutions of an integral equation for transonic flow proposed by Oswatitsch. Solutions are obtained using an iteration process which differs from the classical methods in that the quadratic nature of the integral equation is recognized. Except for phenomena which are predominantly influenced by viscous effects, the results are in good accord with experimental data.

NACA Rept. 1218

EFFECT OF GROUND INTERFERENCE ON THE AERODYNAMIC AND FLOW CHARACTERISTICS OF A 42° SWEPTBACK WING AT REYNOLDS NUMBERS UP TO 6.8×10^6. G. Chester Furlong and Thomas V. Bollech. 1955. ii, 60p. diagrs., photos., tab. (NACA Rept. 1218. Combination of RM L8G22; TN 2487)

The effects of ground interference on the aerodynamic and flow characteristics of a 42° sweptback wing have been determined at distances above the ground 0.68 and 0.92 of the mean aerodynamic chord (measured from 0.25 mean aerodynamic chord). The wing was tested without flaps and with inboard trailing-edge split and outboard leading-edge flaps deflected. The wing had an aspect ratio of 4, a taper ratio of 0.625, and NACA 64_1-112 airfoil sections perpendicular to the 0.273 chord line. The results are, in general, comparable to those reported for unswept wings. The longitudinal stability at the stall was not materially affected at the ground heights of the present tests.

NACA Rept. 1219

MEASUREMENT AND ANALYSIS OF WING AND TAIL BUFFETING LOADS ON A FIGHTER AIRPLANE. Wilber B. Huston and T. H. Skopinski. 1955. i, 27p. diagrs., photo., tabs. (NACA Rept. 1219. Supersedes TN 3080)

Wing and tail buffeting loads measured in 194 runs with a fighter-type airplane are tabulated with the associated flight conditions. Measurements were made at altitudes of 30, 000 to 10, 000 feet and at Mach numbers up to 0.8. Preliminary analysis indicates that the loads vary with the square root of the dynamic pressure and shows the effects of aerodynamic damping, duration of buffeting, maneuver abruptness, penetration beyond the buffet boundary, and reduction of the wing natural frequency in bending through addition of wing-tip weights.

NACA Rept. 1221

THEORETICAL STUDY OF THE TUNNEL-BOUNDARY LIFT INTERFERENCE DUE TO SLOTTED WALLS IN THE PRESENCE OF THE TRAILING-VORTEX SYSTEM OF A LIFTING MODEL. Clarence W. Matthews. 1955. ii, 19p. diagrs. (NACA Rept. 1221. Supersedes RM L53A26)

The equations which represent the interference on the lift of uniformly loaded wings of finite span in circular tunnels with mixed open and closed boundaries are derived, with special attention to those tunnels containing symmetrical arrangements of the open and closed portions. The equations are applicable to tunnels with other cross-sectional shapes, provided a transformation function can be found which will transform the tunnel cross section into a circle.

NACA Rept. 1222

A FREE-FLIGHT WIND TUNNEL FOR AERODYNAMIC TESTING AT HYPERSONIC SPEEDS. Alvin Seiff. 1955. ii, 17p. diagrs., photos. (NACA Rept. 1222. Supersedes RM A52A24)

Research models are fired from a gun through the wind-tunnel test section in a direction opposite to the airstream which has a moderate supersonic Mach number. A wide range of Mach numbers, from low supersonic speeds up to M = 10, can be obtained. The equipment and test techniques are described. The methods used to measure drag, lift-curve slope, center of pressure, and damping in roll are given. The imperfections in the airstream and their effect on model tests are discussed.

NACA Rept. 1226

A METHOD FOR THE DESIGN OF SWEPTBACK WINGS WARPED TO PRODUCE SPECIFIED FLIGHT CHARACTERISTICS AT SUPERSONIC SPEEDS. Warren A. Tucker. 1955. i, 17p. diagrs., tabs. (NACA Rept. 1226. Supersedes RM L51F08)

A method is presented for designing sweptback wings to be self-trimming at a given set of flight conditions. This characteristic is achieved by warping the wing in a particular manner, that is, by giving the wing a certain combination of angle of attack, twist, and camber. The method applies directly to a wide class of sweptback wings. The application to any specific wing is simplified to a routine computational procedure, and a discussion is given of some points to be considered in the application to a practical case. Several illustrative examples are worked out, and the resulting wings are shown to be feasible to construct.

NACA Rept. 1236

ARRANGEMENT OF FUSIFORM BODIES TO REDUCE THE WAVE DRAG AT SUPERSONIC SPEEDS. Morris D. Friedman and Doris Cohen. 1955. ii, 8p. diagrs. (NACA Rept. 1236. Supersedes RM A51I20; TN 3345)

Using linearized slender-body theory and reverse-flow theorems, the wave drag of a system of fusiform bodies at zero angle of attack and supersonic speeds is studied to determine the effect of varying the relative location of the component parts. It is found that in certain arrangements the interference effects are beneficial, and may even result in a two- or three-body system having no more wave drag than the principal body alone. The most favorable location appears to be one in which the maximum cross section of the auxiliary body is slightly forward of the Mach cone from the tail of the main body.

NACA RM E55K02

EVAPORATION OF JP-5 FUEL SPRAYS IN AIR STREAMS. Hampton H. Foster and Robert D. Ingebo. February 1956. 26p. diagrs., tabs. (NACA RM E55K02)

A continuous sampling-probe technique was used to determine quantities of JP-5 fuel spray evaporated under conditions common in ram-jet engines. Fuel was injected contrastream from a multiple-orifice injector, and sampling data were obtained at distances of 7 to 18 inches downstream of the injector for inlet-air velocities from 138 to 370 feet per second, air static pressures of 15 to 35 inches of mercury, absolute, and air temperatures of 80° to 700° F. The results gave the following expression for the fuel evaporated:

$$N = 7.4\, L^{0.33}\, \Delta T^{0.28} \left(\frac{U_a + U_f}{100 + U_a} \right)^2$$

where N is the percentage evaporated, L is the distance downstream of the injector, ΔT is the heat-transfer driving force (air temperature - wet-bulb temperature of fuel drop), U_a is the air velocity, and U_f the injection velocity of the fuel.

NACA RM E55K07

PRELIMINARY FLIGHT SURVEY OF AERODYNAMIC NOISE ON AN AIRPLANE WING. Harold R. Mull and Joseph S. Algranti. March 1956. 8p. diagrs. (NACA RM E55K07)

A brief series of measurements were made in flight of the noise of an airplane-wing turbulent boundary layer. The ratio of the root-mean-square sound pressure to the free-stream dynamic pressure is shown to decrease linearly with increasing Mach number up to Mach number 0.55 and to remain nearly constant thereafter up to near the limiting Mach number of the airplane.

NACA TM 1385

ON THE GAS DYNAMICS OF A ROTATING IMPELLER. (Zur Gasdynamik des drehenden Schaufelsterns). A. Busemann. March 1956. 16p. diagrs. (NACA TM 1385. Trans. from Zeitschrift für angewandte Mathematik und Mechanik, v. 18, no. 1, February 1938, p. 31-38)

It is shown that for a compressible flow with constant entropy the pressure rise maintains the direct relation to the circulation around the blades existing for incompressible flow. In contrast, however, the torque, and with it the power consumption, is increased because of sound waves traveling to infinity already at subsonic circumferential speeds.

NACA TM 1394

A FLAT WING WITH SHARP EDGES IN A SUPERSONIC STREAM. A. E. Donov. March 1956. 48p. diagrs. (NACA TM 1394. Trans. from Akademiia NAUK SSSR, Izvestiia, 1939, p. 603-626)

A basic treatment is given for the approximate solution of the problem of two-dimensional supersonic flow past a thin wing at small angles of attack. The pressure distribution at the surface, the lifting force, and the wave drag are determined.

NACA TM 1397

INTERIM REPORT ON FATIGUE CHARACTERISTICS OF A TYPICAL METAL WING. J. L. Kepert and A. O. Payne. March 1956. 80p. diagrs., photos., tabs. (NACA TM 1397. Originally issued as Report ARL/SM. 207, Aeronautical Research Laboratories, Australia)

Constant amplitude fatigue tests of seventy-two P-51D "Mustang" wings are reported. The tests were performed by a vibrational loading system and by an hydraulic loading device for conditions with and without varying amounts of pre-load. The results indicate that: (a) the frequency of occurrence of fatigue at any one location is related to the range of the loads applied, (b) the rate of propagation of visible cracks is more or less constant for a large portion of the life of the specimen, (c) the fatigue strength of the structure is similar to that of notched material having a theoretical stress concentration factor of more than 3.0, (d) the frequency distribution of fatigue life is approximately logarithmic normal, (e) the relative increase in fatigue life for a given pre-load depends on the maximum load of the loading cycle only, while the optimum pre-load value is approximately 85 percent of the ultimate failing load, and (f) that normal design procedure will not permit the determination of local stress levels with sufficient accuracy to determine the fatigue strength of an element of a redundant structure.

NACA TM 1398

FORMATION OF A VORTEX AT THE EDGE OF A PLATE. (Ausbildung eines Wirbels an der Kante einer Platte). Leo Anton. March 1956. 36p. diagrs. (NACA TM 1398. Trans. from Ingenieur-Archiv, v. 10, 1939, p. 411-427)

The flow about the plate of infinite width may be represented as a potential flow with discontinuity surfaces which extend from the plate edges. For prescribed form and vortex distribution of the discontinuity surfaces, the velocity field may be calculated by means of a conformal representation. One condition is that the velocity at the plate edges must be finite. However, it is not sufficient for determination of the form and vortex distribution of the surface. However, on the basis of a similitude requirement one succeeds in finding a solution of this problem for the plate of infinite width which is correct for the very beginning of the motion of the fluid. Starting from this solution, the further development of the vortex distribution and shape of the surface are observed in the case of a plate of finite width.

NACA TN 3272

GENERALIZED TABLES OF CORRECTIONS TO THERMODYNAMIC PROPERTIES FOR NONPOLAR GASES. Harold W. Woolley and William S. Benedict, National Bureau of Standards. March 1956. 62p. diagrs., tabs. (NACA TN 3272)

Tables are presented based on the Lennard-Jones 6-12 potential for nonpolar molecules for use in representation of second and third virial coefficients and equation-of-state corrections for enthalphy, entropy, specific heats at constant pressure and volume, specific-heat ratio, isentropic expansion coefficient, and sound velocity. The treatment for effects involving three molecules jointly uses an empirical adjustment of the Lennard-Jones parameters within a cluster of three independently of the value for an isolated pair. A graphical correlation of ratios of these parameters with the critical constants is also shown.

NACA TN 3528

A THEORETICAL STUDY OF THE AERODYNAMICS OF SLENDER CRUCIFORM-WING ARRANGEMENTS AND THEIR WAKES. John R. Spreiter and Alvin H. Sacks. March 1956. i, 67p. diagrs., photos., tabs. (NACA TN 3528)

A theoretical study is made of the pressures, loadings, forces, and vortex wake associated with certain cruciform wing arrangements. For 45° bank, the wake of a cruciform wing is treated numerically with 40 vortices and analytically with 4 vortices. Comparisons are made with water-tank measurements, and the calculation of loads on cruciform tails by reverse flow is considered.

NACA TN 3541

A METHOD FOR OBTAINING STATISTICAL DATA ON AIRPLANE VERTICAL VELOCITY AT GROUND CONTACT FROM MEASUREMENTS OF CENTER-OF-GRAVITY ACCELERATION. Robert C. Dreher. February 1956. 21p. diagrs., photo., tabs. (NACA TN 3541)

A method is presented whereby the contact vertical velocities of airplanes are obtained on a statistical basis from measurements of maximum incremental center-of-gravity acceleration. In order to evaluate this method, 268 landings have been made with a small trainer airplane. The vertical-velocity probability curve based on the velocities obtained by this method is compared with the probability curve based on velocities obtained from a trailing-arm velocity indicator. The agreement is very good. A limited amount of data for a medium bomber is presented; these data indicate that the method is probably applicable to large airplanes.

NACA TN 3555

A METHOD FOR CALCULATING THE CONTOUR OF BODIES OF REVOLUTION WITH A PRESCRIBED PRESSURE GRADIENT AT SUPERSONIC SPEED WITH EXPERIMENTAL VERIFICATION. Paige B. Burbank. March 1956. 64p. diagrs., photos., tabs. (NACA TN 3555)

A method using characteristics has been developed for computing the contour of bodies of revolution to give a prescribed pressure gradient in supersonic flow. The contour of a body with a constant pressure gradient at a Mach number of 3.13 was computed. A model was constructed and tested at Mach numbers of 3.05 and 3.13; the agreement with the computed pressure distribution was excellent and the effect of Reynolds number was negligible.

NACA TN 3558

HEAT CAPACITY LAG OF GASEOUS MIXTURES. Thomas D. Rossing, Robert C. Amme, and Sam Legvold, Iowa State College. March 1956. 35p. diagrs., tabs. (NACA TN 3558)

A study was made of the vibrational energy lag in heavy organic gases. Results of measurements of sonic dispersion made with an acoustic interferometer in a number of heavy gases are presented and certain fundamental properties of the vibrational excitation process in these gases are discussed.

NACA TN 3577

THE NICKEL DIP: A RADIOISOTOPE STUDY OF METALLIC DEPOSITS IN PROCELAIN ENAMELING. Joseph C. Richmond, Harry B. Kirkpatrick, and William N. Harrison, National Bureau of Standards. February 1956. 26p. diagrs., photos., tabs. (NACA TN 3577)

Radioisotope tracer techniques were used to study the effect of the nickel dip on the deposition of cobalt metal during firing of a cobalt-bearing ground coat on pickled and sandblasted iron, the effect of surface pretreatment on the amount and distribution of nickel deposited from the nickel dip on enameling iron, and the effect of application and firing of cobalt-free and cobalt-bearing enamels on the chemical form and physical distribution of nickel previously deposited on enameling iron by the nickel dip.

NACA TN 3603

THEORETICAL STUDY OF THE LATERAL FREQUENCY RESPONSE TO GUSTS OF A FIGHTER AIRPLANE, BOTH WITH CONTROLS FIXED AND WITH SEVERAL TYPES OF AUTOPILOTS. James J. Adams and Charles W. Mathews. March 1956. 46p. diagrs., tabs. (NACA TN 3603)

A theoretical approach is used to determine the lateral frequency response of a fighter airplane to side and rolling gusts at a Mach number of 0.7 and an altitude of 30,000 feet. The frequency response to gusts is determined for the airplane with controls fixed and for the airplane in combination with three different basic types of attitude autopilots. The power spectral density of the motion of the airplane in response to gusts is also presented. A discussion of the response of the airplane to command signals is included.

NACA TN 3606

TABULATION OF THE f_λ FUNCTIONS WHICH OCCUR IN THE AERODYNAMIC THEORY OF OSCILLATING WINGS IN SUPERSONIC FLOW. Vera Huckel. February 1956. 59p. tab. (NACA TN 3606)

The integrals which are denoted as the f_λ functions and which occur in the aerodynamic theory for wings oscillating in pure supersonic flow have been evaluated and tabulated for various Mach numbers and values of the reduced frequency. Specific values of parameters λ, M, and k for which tabulations of f_λ are presented are: λ = 0 to 11; Mach numbers of 1.2, 1.3, 1.4, 1.5, 1.6, 1.8, 2.0, 2.5, 3.0, 3.5, 4.0, and 5.0; and values of the reduced frequency k from 0 to 2.0 at the following intervals - 0(0.005)0.15, 0.15(0.01)0.2, 0.2(0.025)0.35, 0.35(0.05)1.0, and 1.0(0.1)2.0. The tabulated values are considered accurate to one in the last digit.

NACA TN 3607

EFFECT OF THICKNESS, CAMBER, AND THICKNESS DISTRIBUTION ON AIRFOIL CHARACTERISTICS AT MACH NUMBERS UP TO 1.0. Bernard N. Daley and Richard S. Dick. March 1956. 75p. diagrs., photos., tab. (NACA TN 3607. Supersedes RM L52G31a)

A modified open-throat type of wind tunnel developed for the purpose of obtaining two-dimensional-airfoil data at Mach numbers near 1.0 is presented and discussed. Tests of a group of related NACA airfoil sections varying in maximum thickness, design lift coefficient, and thickness distribution have been conducted in this wind tunnel at Mach numbers of 0.3 to about 1.0 and at corresponding Reynolds numbers from 0.7×10^6 to 1.6×10^6. Normal-force, drag, and pitching-moment coefficients are presented, together with representative schlieren photographs and pressure-distribution diagrams.

NACA TN 3615

AN EXPERIMENTAL INVESTIGATION OF THE SCALE RELATIONS FOR THE IMPINGING WATER SPRAY GENERATED BY A PLANING SURFACE. Ellis E. McBride. February 1956. 42p. diagrs., photos., tab. (NACA TN 3615)

An experimental investigation was made to determine the scale effects of the forces from water spray generated by a flat rectangular planing surface impinging on a collector plate representative of an aerodynamic surface or other part of a water-based airplane. Two models, one five times the linear dimensions of the other, were tested. The collector plate was located above, and aft of, the spray generator where spray could strike it. Lift and drag force coefficients for both the spray generator and spray collector are presented. Comparisons are made between the large and small models by the Froude scaling relations. An empirical method is presented for correcting the spray friction drag coefficients on a Reynolds number basis.

NACA TN 3616

CHARTS FOR ESTIMATING ROTOR-BLADE FLAPPING MOTION OF HIGH-PERFORMANCE HELICOPTERS. Robert J. Tapscott and Alfred Gessow. March 1956. 19p. diagrs. (NACA TN 3616)

Theoretically derived charts of flapping coefficients are presented for helicopter rotors having blades with a linear twist of 0°, -8°, and -16°. The charts, showing rotor flapping coefficients for combinations of inflow ratio and blade pitch angle, are presented for tip-speed ratios ranging from 0.05 to 0.50. Inasmuch as the theory on which the charts are based does not contain any small-angle assumptions regarding blade-section inflow angles and velocities, the charts are considered applicable, within the limits discussed, for flight conditions involving high inflow velocities and large regions of reversed velocity. The charts do not include stall or compressibility effects.

NACA TN 3617

THEORETICAL ANALYSIS OF LINKED LEADING-EDGE AND TRAILING-EDGE FLAP-TYPE CONTROLS AT SUPERSONIC SPEEDS. E. Carson Yates, Jr. March 1956. 40p. diagrs., tab. (NACA TN 3617)

The use of linked leading-edge and trailing-edge flap-type controls for the purpose of reducing hinge moments at supersonic speeds has been analytically investigated. A series of linked controls with supersonic leading and trailing edges on swept and unswept wings has been studied for Mach numbers of 1.414 and 1.960 by use of the linearized theory of supersonic flows. Variations of lift, rolling moment, and hinge moment with control deflection for these control combinations have been calculated, and the effect of finite wing thickness on these quantities has been estimated. Control characteristics have been tabulated for the condition of equal leading-edge and trailing-edge flap deflection, and the deflection ratios necessary for zero resultant hinge moment have also been listed.

NACA TN 3618

EXPERIMENTAL INVESTIGATION OF THE VIBRATIONS OF A BUILT-UP RECTANGULAR BOX BEAM. Eldon E. Kordes and Edwin T. Kruszewski. February 1956. 28p. diagrs., photos., tabs. (NACA TN 3618)

Experimental modes and frequencies of a uniform built-up box beam are presented and comparisons are made between experimental and theoretical frequencies. For bending vibrations, frequencies obtained from an analysis of a substitute-stringer structure which includes the influence of transverse shear deformation and shear lag were found to agree very well with those obtained experimentally. In the case of torsional vibrations, the frequencies obtained from either an elementary or a four-flange beam analysis which includes the effects of restraint of warping were found to be in satisfactory agreement with the experimental frequencies.

NACA TN 3619

EFFECT OF CARRIAGE MASS UPON THE LOADS AND MOTIONS OF A PRISMATIC BODY DURING HYDRODYNAMIC IMPACT. Melvin F. Markey. March 1956. 45p. diagrs. (NACA TN 3619)

Theoretical equations for the effect of a towing-carriage mass upon the loads and motions of a prismatic body during a hydrodynamic impact are presented. These equations apply to any prismatic-body impact depending only upon the variables substituted. The correction to the free-body case (the body without any horizontal or vertical restraints) is seen to vary with trim and carriage mass for a given model. The deeply immersed and the nonimmersed chines are treated separately. Curves comparing the condition of infinite carriage mass (constant horizontal velocity) with zero carriage mass (free-body case) are given to indicate the importance of the carriage-mass effect.

NACA TN 3620

THE DESIGN OF A MINIATURE SOLID-PROPELLANT ROCKET. Robert H. Heitkotter. March 1956. 13p. diagrs., photo., tab. (NACA TN 3620)

A miniature rocket motor was designed and developed to exert 3 ounces of thrust for a duration of 2 seconds. The rocket has reproducible performance and is simply constructed. The research that led to the development of the miniature rocket showed that compensatory measures must be used in designing extremely small rockets because of excessive heat-transfer rates.

NACA TN 3622

PRELIMINARY STUDY OF SOME FACTORS WHICH AFFECT THE STALL-FLUTTER CHARACTERISTICS OF THIN WINGS. A. Gerald Rainey. March 1956. 33p. diagrs., photo., tab. (NACA TN 3622. Supersedes RM L52D08)

The results of an exploratory, analytical, and experimental study of some of the factors which might be of importance in the stall flutter of thin wings are presented. The factors considered were Mach number, Reynolds number, density, aspect ratio, sweepback, structural damping, location of torsion nodal line, and concentrated weights.

NACA TN 3623

CORRELATION OF SUPERSONIC CONVECTIVE HEAT-TRANSFER COEFFICIENTS FROM MEASUREMENTS OF THE SKIN TEMPERATURE OF A PARABOLIC BODY OF REVOLUTION (NACA RM-10). Leo T. Chauvin and Carlos A. deMoraes. March 1956. 38p. diagrs., photo., tabs. (NACA TN 3623. Supersedes RM L51A18)

Free-flight tests at supersonic speeds have been made to determine the local convective heat-transfer coefficients, evaluated from measured skin temperatures along the body of a rocket-propelled fin-stabilized parabolic body of revolution (NACA RM-10). The Mach number range covered was 1.02 to 2.48 and the Reynolds number range was 3.18×10^6 to 163.85×10^6. The experimental values are compared with the results obtained from the V-2 research missile and also with several equations for heat transfer in a turbulent boundary layer.

NACA TN 3626

EXPERIMENTAL INVESTIGATION OF THE FLOW AROUND LIFTING SYMMETRICAL DOUBLE-WEDGE AIRFOILS AT MACH NUMBERS OF 1.30 AND 1.41. Paul B. Gooderum and George P. Wood. March 1956. 86p. diagrs., photos. (NACA TN 3626)

Measurements were made of the flow around a 10-percent-thick, doubly symmetrical, two-dimensional wedge at a Mach number of 1.30 and a 14.2-percent-thick wedge at Mach numbers of 1.30 and 1.41 for various angles of attack up to 5°. Pressure and Mach number distributions, lift and drag coefficients, center of lift, and pitching moment are presented for the angles of attack used. By means of the transonic similarity laws, the results are compared with each other, with small-disturbance theory, and with shock-expansion theory wherever possible. The data show that pressure distributions on wedges of different thickness and Mach number are similar at the same values of transonic similarity parameter and reduced angle of attack for angles of attack as large as the thickness ratio and that the lift-curve slope and chordwise position of the center of pressure are only roughly independent of angle of attack for the range of angles investigated.

NACA TN 3627

BOUNDARY-LAYER GROWTH AND SHOCK ATTENUATION IN A SHOCK TUBE WITH ROUGHNESS. Paul W. Huber and Donald R. McFarland. March 1956. 49p. diagrs., photos., tab. (NACA TN 3627)

Measurements of unsteady-flow turbulent boundary-layer characteristics using a new bullet technique involving study of the bullet bow-wave shape and of shock-wave attenuation have been made in a shock tube with wall roughness. The boundary-layer-thickness measurements agreed well with both steady-flow data and theory. The measured velocity profiles were considerably less full than the steady-flow theoretical profiles but agreed with some of the steady-flow data. The shock-attenuation measurements were in agreement with a simple theory at small values of displacement thickness but were much lower than theory at the large values.

NACA TN 3629

INVESTIGATION OF THE EFFECTS OF GROUND PROXIMITY AND PROPELLER POSITION ON THE EFFECTIVENESS OF A WING WITH LARGE-CHORD SLOTTED FLAPS IN REDIRECTING PROPELLER SLIPSTREAMS DOWNWARD FOR VERTICAL TAKE-OFF. Richard E. Kuhn. March 1956. 38p. diagrs., photos., tab. (NACA TN 3629)

Results are presented of an investigation of the effects of proximity to the ground on the effectiveness of large-chord slotted flaps in redirecting propeller slipstreams downward for vertical take-off. The model consisted of a semispan wing equipped with a 60-percent-chord and 30-percent-chord slotted flap operating in the slipstream of two large-diameter propellers. The tests were conducted at zero forward speed in a large room. The results indicate that the adverse effect of the ground can be reduced somewhat by mounting the propellers with their thrust axis below the wing chord plane.

NACA TN 3630

HOVERING-FLIGHT TESTS OF A MODEL OF A TRANSPORT VERTICAL-TAKE-OFF AIRPLANE WITH TILTING WING AND PROPELLERS. Powell M. Lovell, Jr., and Lysle P. Parlett. March 1956. 23p. diagrs., photo., tab. (NACA TN 3630)

An investigation of the take-off, landing, and hovering-flight characteristics of a four-engine transport vertical-take-off airplane with tilting wing and propellers has been conducted with a remotely controlled free-flight model. The model had four propellers distributed along the wing with the thrust axes in the wing-chord plane. In order to produce direct lift for hovering flight with the fuselage horizontal, the wing and propellers were rotated 90° relative to the fuselage. It was found that the model could be flown satisfactorily for the conditions covered in the investigations.

NACA TN 3631

RESULTS OF AXIAL-LOAD FATIGUE TESTS ON ELECTRO-POLISHED 2024-T3 AND 7075-T6 ALUMINUM-ALLOY-SHEET SPECIMENS WITH CENTRAL HOLES. Charles B. Landers and Herbert F. Hardrath. March 1956. 47p. diagrs., tabs. (NACA TN 3631)

Results are presented of axial-load fatigue tests at stress ratios of 0 and -1.0 on electropolished 2024-T3 (24S-T3) and 7075-T6 (75S-T6) aluminum-alloy-sheet specimens with central holes. The specimen widths and hole diameters were varied in order to provide data suitable for a study of notch-size effect. The data are compared with previously published results of tests on unnotched electropolished specimens and on unpolished specimens containing central holes.

NACA TN 3633

ANALYSIS OF THE ULTIMATE STRENGTH AND OPTIMUM PROPORTIONS OF MULTIWEB WING STRUCTURES. B. Walter Rosen. March 1956. 34p. diagrs., tabs. (NACA TN 3633)

A structural-efficiency analysis of multiweb wing structures is presented. Minimum structural weight is shown as a function of the design variables in a manner which makes comparisons possible with structures of different materials or with other types of construction. The structural-efficiency chart presented is based on equations developed to relate ultimate bending strength of multiweb beams which fail in the local buckling mode to beam proportions and material properties and is substantiated by the results of multiweb-beam bending tests.

NACA TN 3653

SOME EFFECTS OF BLUNTNESS ON BOUNDARY-LAYER TRANSITION AND HEAT TRANSFER AT SUPERSONIC SPEEDS. W. E. Moeckel. March 1956. 43p. diagrs. (NACA TN 3653)

Large downstream movements of transition observed when the leading edges of a hollow cylinder or a flat plate are slightly blunted are explained in terms of the reduction in Reynolds number at the outer edge of the boundary layer due to the detached shock wave. This Reynolds number reduction leads to a predicted downstream movement of transition which is in good agreement with the hollow-cylinder result at Mach 3.1. Application of this theory to other Mach numbers yields the result that blunting the tip of slender cones or the leading edge of thin wedges should produce downstream movements of transition by factors ranging from 2 at Mach number 3.0 to 30 at Mach number 15.

NACA TN 3657

FRICTION STUDIES OF GRAPHITE AND MIXTURES OF GRAPHITE WITH SEVERAL METALLIC OXIDES AND SALTS AT TEMPERATURES TO 1000° F. Marshall B. Peterson and Robert L. Johnson. February 1956. 16p. diagrs., photos. (NACA TN 3657)

Powdered graphite lubricated metal surfaces at temperatures in the vicinity of 1000° F when a metallic oxide film could be formed and maintained. Mixtures of soft metallic oxides such as lead oxide or cadmium oxide with graphite were effective lubricants at all temperatures from room temperature to 1000° F unless a chemical reaction occurred between the graphite and the oxide.

NACA TN 3659

EFFECT OF LEADING-EDGE GEOMETRY ON BOUNDARY-LAYER TRANSITION AT MACH 3.1. Paul F. Brinich. March 1956. 44p. diagrs., tabs. (NACA TN 3659)

The effect of leading-edge geometry on transition, recovery factor, boundary-layer profile, and the roughness required to induce transition was studied. A downstream displacement of transition and an increase in recovery factor with increasing leading-edge bluntness were found. These were associated with the formation of an inviscid shock-produced shear layer originating at the leading edge. The laminar boundary layer was found to develop within the low Mach number, low Reynolds number region of the shock-produced shear layer for appreciable distances, even when the degree of leading-edge blunting was small. Some effects of leading-edge blunting on roughness-induced transition and the effect of surface heat conductivity on measured temperature distributions were also studied.

NACA TN 3662

THEORETICAL LOSS RELATIONS FOR LOW-SPEED TWO-DIMENSIONAL-CASCADE FLOW. Seymour Lieblein and William H. Roudebush. March 1956. 46p. diagrs., tab. (NACA TN 3662)

A theoretical analysis is conducted of the relations existing between total-pressure defect and wake momentum thickness and form factor for the incompressible flow across a two-dimensional cascade. Both the loss at a plane of measurement and the complete loss after mixing are considered. The relative importance of the various factors entering the loss relations is evaluated. Relations are obtained for the mixing-loss ratio and for the effect of trailing-edge thickness. The application of the results of the analysis to the estimation of profile loss and to the correlation of loss data is discussed.

NACA TN 3664

SUMMARY OF SCALE-MODEL THRUST-REVERSER INVESTIGATION. John H. Povolny, Fred W. Steffen, and Jack G. McArdle. February 1956. 49p. diagrs., photos. (NACA TN 3664)

This report summarizes the results of a scale-model thrust-reverser investigation. Three basic types of thrust reversers, target, tail-pipe cascade, and ring cascade, were investigated. All three were found to have satisfactory reverse-thrust performance and thrust-modulation characteristics.

NACA TN 3668

PRELIMINARY INVESTIGATION OF A FAMILY OF DIFFUSERS DESIGNED FOR NEAR SONIC INLET VELOCITIES. Richard Scherrer and Warren E. Anderson. February 1956. 43p. diagrs., photo. (NACA TN 3668)

Empirical equations defining a family of diffusers were evolved and several shapes were tested with both separated and unseparated initial boundary layers. The results indicate these diffuser shapes to be satisfactory; however, initial boundary-layer thickness was found to be as important as duct shape. Extended throat lengths were advantageous only with separated initial boundary layers. Effects of duct center-line offset were found to be large and adverse but the effects of surface condition, in general, were small.

NACA TN 3679

INFLUENCE OF COPPER IONS ON ADHERENCE OF VITREOUS COATINGS TO STAINLESS STEEL. D. G. Moore and A. G. Eubanks, National Bureau of Standards. February 1956. 14p. diagrs., photos., tabs. (NACA TN 3679)

In another phase of an investigation of adherence of ceramic coatings to metals, the effect of copper oxide in promoting adherence of vitreous coatings to AISI type 321 stainless steel was studied. The goal of this particular study was to determine whether the action of the copper ions was similar to that of cobalt ions in coatings for iron or whether the two actions were entirely different.

MODEL SELECTION AND DESIGN PRACTICES APPLICABLE TO THE DEVELOPMENT OF SPECIFIC AIRCRAFT. Donald D. Baals. (Presented to Wind Tunnel and Model Testing Panel of the Advisory Group for Aeronautical Research and Development, Rome, Italy, February 20-25, 1956). 29p. diagrs., photos.

The critical nature of transonic and supersonic flows has limited the generalization of research results and has led to a need for extensive specific model investigations. This paper discusses the pertinent background information relative to a specific model development program, the major aerodynamic and mechanical requirements of model design, and the array of models required for a typical development program in the U. S. This paper considers the aerodynamic problems of the airframe, including the influence of inlets, but excludes the internal aerodynamics of the engine proper.

CONTRIBUTION OF THE STUDY OF SUPERSONIC AXIAL COMPRESSORS. (Contribution à l'etude des Compresseurs Axiaux Supersoniques). Pierre Schwaar. November 1955. 20p. diagrs. (Trans. from Zeitschrift für angewandte Mathematik und Physik, v. 5, no. 2, 1954, p. 136-150)

In studying the three-dimensional flow in a supersonic axial compressor, the normal-shock-in-stator case has been considered. It is shown that the kinematic and dynamic conditions which are necessary to produce a normal shock wave and a radially stable transonic flow are very restrictive. The radial distribution of the flow angles in front of the shock wave is found to be that of the classical irrotational gyratory flows. The radial equilibrium condition of the flow on both sides of the shock wave requires a well-determined radial distribution of the Mach numbers of the velocities approaching the shock, which results in a nonuniform radial energy distribution of the transonic flow. A numerical example shows the importance of the radial effects. Critical comments are made on the shock-in-rotor case.

ON RELATIONSHIPS BETWEEN THE GRAPHICAL AND THE ALGEBRAIC STABILITY CRITERIA. (Uber Zusammenhänge zwischen den graphischen und den algebraischen Stabilitätskriterien). Wolfgang Hahn. January 1956. 3p. (Trans. from Zeitschrift für angewandte Mathematik und Mechanik, v. 35, no. 3, March 1955, p. 119)

This derivation, which seems to be new, presents a very simple proof of the stability criterion of Routh, with the aid of that of Nyquist. It is well known that the criteria of Routh and of Hurwitz, on the one hand, those of Hyquist and of Leonhard, on the other, may be easily converted into one another so that the relationship between all four criteria becomes evident.

THEORETICAL METHODS OF BALLISTICS. SECOND PART: INTERNAL BALLISTICS. (Méthodes Théoriques de la Balistique, Deuxieme Partie, Balistique Intérieure). P. Carrière. February 1956. 14p. diagr. (Trans. from Actes du Colloque International de Mécanique, v. II, 1950, Étude sur la Mécanique des Fluides. Publications Scientifiques et Techniques du Ministére de l'Air, no. 250, 1951, p. 26-36)

Previous works are discussed and a brief sketch of a theory which was the subject of a communication to the VII Congress of Applied Mechanics in London is given. The simplifying hypotheses have been reduced to the mathematically indispensible minimum. The numerical or graphical calculations which this method requires remain still practical. An example of application is given. The velocity of the projectile at every instant can be calculated by this method.

N-41759*

THE NOZZLE CANNON. (Le Canon á Tuyére). M. Touchard. (Includes Conclusion by Mr. Cassagnou). February 1956. 17p. diagrs. (Trans. from Actes du Colloque International de Mécanique. v. II., 1950, Etude sur la Mécanique des Fluides. Publications Scientifiques et Techniques du Ministére de l'Air, no. 250, 1951, p. 95-107)

The term "nozzle cannon" is used to represent a cannon in which the combustion chamber containing the powder and the barrel containing the projectile are separated by a nozzle. The phenomena which take place in the cannon are described. A lower prèssure is artificially achieved in the barrel than in the chamber, with the twofold goal of permitting the firing of a rather fragile finned projectile and a reduction in the weight of the weapon.

NACA RM A7J27

EXPERIMENTAL INVESTIGATION AT SUPERSONIC SPEEDS OF TWIN-SCOOP DUCT INLETS OF EQUAL AREA. I. - AN INLET ENCLOSING 61.5 PERCENT OF THE MAXIMUM CIRCUMFERENCE OF THE FOREBODY. Wallace F. Davis and David L. Goldstein. January 21, 1948. 16p. diagrs., photos. (NACA RM A7J27)

This report contains the results of an investigation made at Mach numbers between 1.36 and 2.01 of the total pressure recovery attainable with a twin-scoop duct inlet. The results include an experimental study of the optimum ramp to be placed upstream of the inlet and also a comparison between the twin-scoop inlet and an annular inlet of the same entrance area. It was found that the maximum recovery of total pressure is attained with a ramp angle of 5°. This recovery is about 10 percent greater than that of the corresponding annular entrance or it is about four-fifths of that of a normal shock wave occurring at the same free-stream Mach number.

NACA RM A8C11

EXPERIMENTAL INVESTIGATION AT SUPERSONIC SPEEDS OF TWIN-SCOOP DUCT INLETS OF EQUAL AREA. II - EFFECTS OF SLOTS UPON AN INLET ENCLOSING 61.5 PERCENT OF THE MAXIMUM CIRCUMFERENCE OF THE FOREBODY. Wallace F. Davis and David L. Goldstein. June 9, 1948. 15p. diagrs., photos. (NACA RM A8C11)

This report contains the results of an investigation made at Mach numbers between 1.36 and 2.01 of the pressure recovery attainable with a twin-scoop duct inlet having slots in the walls of the duct contiguous to the forebody and immediately behind the inlet. It was found that boundary-layer air flowed out of the diffuser through the slots, thereby improving the flow stability. Because of this improvement, a greater ramp angle could be used than with the unslotted inlet. The maximum total-pressure ratio of a twin-scoop duct entrance having a 9° ramp and slots of which the width was 48.6 percent of the depth of a scoop was about seven-eighths of the pressure recovered through a normal shock wave occurring at the test Mach number.

NACA RM A8E04

EXPERIMENTAL INVESTIGATION AT SUPERSONIC SPEEDS OF TWIN-SCOOP DUCT INLETS OF EQUAL AREA. III - INLET ENCLOSING 37.2 PERCENT OF THE MAXIMUM CIRCUMFERENCE OF THE FOREBODY. Wallace F. Davis and Sherman S. Edwards. July 22, 1948. 25p. diagrs., photos. (NACA RM A8E04)

The results of an experimental investigation at supersonic speeds of the total-pressure recovery attainable after diffusion with twin-scoop duct inlets enclosing 37.2 percent of the circumference of the forebody are presented. Tests of the effects of inlet proportions, ramp angle, slot dimensions, and angles of attack and yaw upon the mass flow and pressure recovery at Mach numbers between 1.36 and 2.01 are discussed. The pressure recovery attained with a model having a slotted inlet with a 12° ramp was equal to that of a normal shock wave occurring at the test Mach number.

NACA RM A9A31

EXPERIMENTAL INVESTIGATION AT SUPERSONIC SPEEDS OF TWIN-SCOOP DUCT INLETS OF EQUAL AREA. IV - SOME EFFECTS OF INTERNAL DUCT SHAPE UPON AN INLET ENCLOSING 37.2 PERCENT OF THE FOREBODY CIRCUMFERENCE. Wallace F. Davis, Sherman S. Edwards, and George B. Brajnikoff. March 15, 1949. 21p. diagrs., photos. (NACA RM A9A31)

The total pressure recovery attainable at Mach numbers between 1.36 and 2.01 with models having twin-scoop inlets and two types of internal diffuser is compared. It is shown that a large increase in the maximum total-pressure ratio can be attained by improving the conditions for boundary-layer flow in the diffuser. At Mach numbers of 1.7 and less, the pressure recovery attained was within 2 percent of that associated with nose inlets.

NACA RM A51C12

CHARACTERISTICS OF FOUR NOSE INLETS AS MEASURED AT MACH NUMBERS BETWEEN 1.4 AND 2.0. George B. Brajnikoff and Arthur W. Rogers. June 25, 1951. 48p. diagrs., photos. (NACA RM A51C12)

The performance characteristics of two open-nose and two conical-shock diffusers were measured at supersonic speeds between $M_0 = 1.4$ and 2.0 at angles of attack of 0°, 3°, 6°, and 9°. Schlieren photographs of flow about the models at 0° angle of attack were used to calculate external wave drag; these values of drag agreed well with those obtained by direct force measurements after addition of skin-friction drag, except in cases of reduced mass-flow ratios.

NACA RM A51C13

A COMPARISON OF THE EXPERIMENTAL AND THEORETICAL LOADING OVER TRIANGULAR WINGS IN SIDESLIP AT SUPERSONIC SPEEDS. John W. Boyd. May 18, 1951. 58p. diagrs., photo., tabs. (NACA RM A51C13)

The results of an experimental investigation of the load distribution over two triangular wings in sideslip at Mach numbers from 1.20 to 1.70 are presented and compared with theory. The two wings tested have identical plan form, 45° sweepback of the leading edge, and an aspect ratio of 4.0. One model was composed of round-nose airfoil sections and the other of sharp-nose, biconvex sections. For both wings the maximum thickness of streamwise sections was 6 percent and was located at the 30-percent chord.

NACA RM A51C27

DRAG INTERFERENCE BETWEEN A POINTED CYLINDRICAL BODY AND TRIANGULAR WINGS OF VARIOUS ASPECT RATIOS AT MACH NUMBERS OF 1.50 AND 2.02. Elliott D. Katzen and George E. Kaattari. May 23, 1951. 45p. diagrs., photos., tabs. (NACA RM A51C27)

The drag of a body alone, six triangular wings of various aspect ratios, and the combinations were measured at Mach numbers of 1.50 and 2.02 at a Reynolds number of 5.5 million (based on the body length). The experimental drag-interference results were in accordance with calculations based on NACA RM A9E19, 1949, with skin-friction effects taken into account, the interference effect being principally the result of fixing transition on the body by adding a wing.

NACA RM A52C14

AN ANALYTICAL STUDY OF THE COMPARATIVE PERFORMANCE OF FOUR AIR-INDUCTION SYSTEMS FOR TURBOJET-POWERED AIRPLANES DESIGNED TO OPERATE AT MACH NUMBERS UP TO 1.5. James R. Blackaby. June 1952. 38p. diagrs. (NACA RM A52C14)

A design study was made to determine some of the operational characteristics of four air-induction systems with scoop-type inlets for an angle of attack of 0°. The systems were designed for operation with free-stream Mach numbers from 0.85 to 1.50 at an altitude of 35,332 feet. They included examples with and without oblique shock ramps ahead of the inlets, with both fixed and variable inlet geometry, and with divergent diffusers. A comparative evaluation of the four systems was made on the basis of a summation of three drag factors. These factors were calculated for additive drag, the thrust loss accompanying the assumed total-pressure loss, and the energy loss associated with bypassing excess air taken in by the air-induction systems.

NACA RM A53B02

AN EXPERIMENTAL INVESTIGATION OF THE ZERO-LIFT-DRAG CHARACTERISTICS OF SYMMETRICAL BLUNT-TRAILING-EDGE AIRFOILS AT MACH NUMBERS FROM 2.7 TO 5.0. Clarence A. Syvertson and Hermilo R. Gloria. April 1953. 31p. diagrs., photos., tabs. (NACA RM A53B02)

The zero-lift-drag characteristics of nine symmetrical airfoils were investigated experimentally at Mach numbers from 2.7 to 5.0 and Reynolds numbers (based on the chord) from 0.35 million to 3.63 million. Eight of these airfoils had blunt trailing edges and were designed to have minimum pressure drag at a Mach number of 3 or 5 for a given torsional rigidity or a given bending strength. The ninth airfoil was a conventional biconvex section having a torsional rigidity equal to that of three of the minimum-drag airfoils. Section thickness ratios varied from 3.74 to 6.10 percent.

NACA RM A54C31

THE EFFECT OF BLUNT-TRAILING-EDGE MODIFICATIONS ON THE HIGH-SPEED STABILITY AND CONTROL CHARACTERISTICS OF A SWEPT-WING FIGHTER AIRPLANE. Melvin Sadoff, Frederick H. Matteson, and Rudolph D. Van Dyke, Jr. May 1954. 55p. diagrs., photos., tab. (NACA RM A54C31)

An investigation was conducted on a 35° swept-wing fighter airplane to determine the effects of several blunt-trailing-edge modifications to the wing and tail on the stability and control characteristics and tracking performance. Significant improvement in the pitch-up and roll-off characteristics for the blunt-aileron modification was noted at high Mach numbers.

NACA RM A55A07

DOWNWASH SURVEY BEHIND TWO LOW-ASPECT-RATIO VARIABLE-INCIDENCE WINGS IN COMBINATION WITH THREE DIFFERENT SIZE FUSELAGES AT A MACH NUMBER OF 0.25. Edward J. Hopkins and Norman E. Sorensen. March 1955. 54p. diagrs., photos., tab. (NACA RM A55A07)

Measurements were made of the downwash fields behind six wing-body combinations at a Mach number of 0.25. A triangular wing (aspect ratio 2.0) and a trapezoidal wing (aspect ratio 3.0) were tested in combination with three geometrically similar bodies of revolution. The ratios of maximum body diameter to wing span were 0.196, 0.259, and 0.343. The wings were set at several angles of incidence from 0° to 10°.

NACA RM E8C17

NACA RM E8C22

SOME EFFECTS OF GUTTER FLAME-HOLDER DIMENSIONS ON COMBUSTION-CHAMBER PERFORMANCE OF 20-INCH RAM JET. Fred A. Wilcox, Eugene Perchonok, and George Wishnek. July 30, 1948. 39p. diagrs., photos., tab. (NACA RM E8C22)

Operational characteristics of 20-inch ram jet with four different gutter-grid flame holders and an adjustable three-gutter flame holder were investigated. Best overall operation was obtained with one gutter-grid flame holder operated to maximum combustion-chamber-inlet velocity of 201 feet per second. Double-scale, three-quarter-scale, and 1.4-spaced versions of this flame holder generally gave unsatisfactory operation. Results obtained with adjustable three-gutter flame holder indicate that the flame holder should block about 50 percent of combustion-chamber frontal area to attain operation at choking conditions at exhaust-nozzle outlet for configuration investigated.

NACA RM E51C05

PRELIMINARY INVESTIGATION OF HELMHOLTZ RESONATORS FOR DAMPING PRESSURE FLUCTUATIONS IN 3.6-INCH RAM JET AT MACH NUMBER 1.90. Jerome L. Fox. May 22, 1951. 24p. diagrs., photos. (NACA RM E51C05)

The feasibility of damping pressure pulsations in a typical ram-jet configuration by means of attached Helmholtz resonators was investigated at Mach number 1.90. With one of the two resonators used a reduction in movement of the shock at the inlet was noted, together with an increase of 4 percent in total-pressure recovery when the ram jet was operating near peak pressure recovery. Neither resonator was successful in damping oscillations over the entire range of operating conditions.

NACA RM E51C06

AERODYNAMIC CHARACTERISTICS OF FOUR BODIES OF REVOLUTION SHOWING SOME EFFECTS OF AFTERBODY SHAPE AND FINENESS RATIO AT FREE-STREAM MACH NUMBERS FROM 1.50 TO 1.99. Robert J. Cohen. May 22, 1951. 31p. diagrs., tabs. (NACA RM E51C06)

The effects of fineness ratio (14.2 and 12.2) and boattailing on aerodynamic characteristics of four bodies of revolution at Mach numbers from 1.50 to 1.99 within a range of angles of attack from 0° to 10° at an approximate Reynolds number of 35×10^6 based on body length were investigated. A comparison of experimental data with available theory is included. At zero angle of attack, fineness ratio has no appreciable effect on model characteristics while boattailing and boattail convergence significantly affect fore drag and base drag. At angle of attack the effects are singular. The theory presented by H. J. Allen is a significant improvement over linearized potential theory in predicting aerodynamic characteristics.

NACA RM E52J16

INVESTIGATION OF EFFECTS OF ADDITIVES ON STORAGE PROPERTIES OF FUMING NITRIC ACIDS. Charles E. Feiler and Gerald Morrell. December 1952. 25p. photos., diagrs., tabs. (NACA RM E52J16)

The storage properties of fuming nitric acids, with and without additives, were investigated at a temperature of 170° F in closed containers of approximately 100-milliliter capacity. It was found that at equal ullages the peak decomposition pressures of white fuming nitric acid are of an order of magnitude greater than those of red fuming nitric acid. Addition of 1 percent potassium fluoride dihydrate was found to be the most effective of the additives investigated in reducing the rate of pressure rise and in reducing corrosion on aluminum and stainless steel surfaces. This additive had no effect on the ignition delay of a representative fuel at 70° F even after 100 hours of storage.

NACA RM E53C25

COMPARATIVE TENSILE STRENGTHS AT 1200° F OF VARIOUS ROOT DESIGNS FOR CERMET TURBINE BLADES. Andre J. Meyer, Jr., Albert Kaufman, and Howard F. Calvert. June 1953. 23p. diagrs., photos., tabs. (NACA RM E53C25)

Tensile tests were conducted on five roots designed for use with brittle materials and the results are compared with the strength of the conventional fir-tree type blade root. Three of the roots tested were found superior to the fir-tree design and are suitable for application in the turbine of aircraft jet engines. The turbine-rotor segments for these blade roots were also evaluated and established as satisfactory for normal operation in a J33-A-33 engine. A ductile material inserted between the blade root and the rotor recess proved beneficial.

NACA RM E53L17b

INVESTIGATION OF EFFECT OF FLUORIDE ON CORROSION OF 2S-0 ALUMINUM AND 347 STAINLESS STEEL IN FUMING NITRIC ACID AT 170° F. Charles E. Feiler and Gerald Morrell. February 1954. 22p. diagrs., photos., tabs. (NACA RM E53L17b)

The effect of small additions of fluoride on the corrosion of 2S-0 aluminum and 347 stainless steel by fuming nitric acid at 170° F has been evaluated quantitatively by the determination of the weight loss of metal specimens immersed in the acid. The ratio of metal surface area to volume of acid was approximately 7.5 inch^{-1} in all cases. It was found that for acids containing no fluorides the weight loss of aluminum was approximately 1/5 that of stainless steel. Addition of 1 percent fluoride ion to the acid reduced the weight loss of both metals to practically zero even after 26 days of exposure to the acid at 170° F.

The minimum quantity of fluoride ion required to inhibit corrosion was found to be approximately 0.25 and 0.5 percent for aluminum and stainless steel, respectively, in white fuming nitric acid and 0.5 and 1 percent for aluminum and stainless steel, respectively, in red fuming nitric acid (18 percent nitrogen dioxide). These fluoride percentages were based on the total weight of acid. Provided the concentration of fluoride ion was sufficient to inhibit corrosion, the source of these ions was immaterial. Additional information concerning the effect of fluorides on corrosion was obtained by measuring the electrode potentials of the metals against a platinum reference electrode.

NACA RM L9C03

PLANING CHARACTERISTICS OF THREE SURFACES REPRESENTATIVE OF HYDRO-SKI FORMS. Kenneth L. Wadlin and John R. McGehee. March 29, 1949. 94p. diagrs., photos., tab. (NACA RM L9C03)

The planing characteristics as determined by tank tests, are presented for three surfaces representative of hydro-ski forms. One surface was of rectangular plan form with a flat bottom; the second surface had a rectangular plan form with transversely curved bottom; and the third surface had a flat bottom but was triangular in plan form. The range of trims investigated was 4° to 20°. The data are presented in the form of plots of the total load, resistance, trimming moment, and draft against wetted area. Plots of wetted length, wetted area forward of the observed wetted length at the chine, and aerodynamic tare forces are included.

NACA RM L9C31

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A SEMISPAN WIND-TUNNEL MODEL OF A TAILLESS AIRPLANE AND A COMPARISON WITH COMPLETE-MODEL WIND-TUNNEL TESTS AND SEMISPAN-MODEL WING-FLOW TESTS. Kenneth W. Goodson and Thomas J. King, Jr. October 10, 1949. 63p. diagrs., photos. (NACA RM L9C31)

An investigation was conducted on a semispan model of a tailless airplane in the Langley high-speed 7- by 10-foot tunnel in the Mach number range from 0.40 to 0.97. The results are compared with those obtained with sting-mounted complete model tested in the same tunnel and with a semispan model tested by the wing-flow method.

NACA RM L9J06

EXPERIMENTAL INVESTIGATION OF VARIOUS WING-MOUNTED EXTERNAL STORES ON A WING-FUSELAGE COMBINATION HAVING A SWEPTBACK WING OF INVERSE TAPER RATIO. Kenneth P. Spreemann and H. Norman Silvers. September 15, 1950. 29p. diagrs., photos., tab. (NACA RM L9J06)

An investigation was conducted in the Langley high-speed 7- by 10-foot tunnel to determine the effects of several wing-mounted external-store configurations on the aerodynamic characteristics of a small-scale model of a sweptback wing-fuselage combination. The external-store configurations investigated included inboard under-wing installations (pylon-suspended and flush-wing stores) and wing-tip installations (forward-tip and central-tip stores).

NACA RM L51C08

RESULTS OF TWO FREE-FALL EXPERIMENTS ON FLUTTER OF THIN UNSWEPT WINGS IN THE TRANSONIC SPEED RANGE. William T. Lauten, Jr., and Herbert C. Nelson. May 8, 1951. 26p. diagrs., photo., tabs. (NACA RM L51C08)

Results of four thin unswept flutter airfoils attached to two freely falling bodies are reported. Two airfoils fluttered at a Mach number of 0.85, a third airfoil fluttered at a Mach number of 1.03, and a fourth fluttered at a Mach number of 1.07. Results of calculations of flutter speed using incompressible and compressible air-force coefficients, including Mach number of 1.0, are presented.

NACA RM L51C30

LOW-SPEED LONGITUDINAL AND WAKE AIRFLOW CHARACTERISTICS AT A REYNOLDS NUMBER OF 5.5×10^{6} OF A CIRCULAR-ARC 52° SWEPTBACK WING WITH A FUSELAGE AND A HORIZONTAL TAIL AT VARIOUS VERTICAL POSITIONS. Gerald V. Foster and Roland F. Griner. June 19, 1951. 44p. diagrs., tabs. (NACA RM L51C30)

The results of a low-speed investigation are presented to determine the effects of a fuselage and horizontal tail on the longitudinal characteristics of a circular-arc 52° sweptback wing at a Reynolds number of 5.5×10^{6}. The paper also presents the characteristics of the air flow behind the wing at one station representative of a horizontal tail location. These results were obtained with the plain wing configuration and with the wing equipped with leading-edge and trailing-edge flaps.

NACA RM L51H20

COMPARISON OF NACA 65-SERIES COMPRESSOR-BLADE PRESSURE DISTRIBUTIONS AND PERFORMANCE IN A ROTOR AND IN CASCADE. Willard R. Westphal and William R. Godwin. November 1951. 53p. diagrs., photos. (NACA RM L51H20)

An investigation has been conducted to compare the performance of NACA 65-series compressor blades in two-dimensional cascade to that in an axial flow compressor. Blade pressure distributions were obtained by the use of a mercury-seal pressure transfer device. The comparison indicated that cascade data accurately predicted the turning angle and blade pressure distribution obtained in the compressor at design conditions.

NACA RM L51J16

EFFECT OF SECTION THICKNESS AND TRAILING-EDGE RADIUS ON THE PERFORMANCE OF NACA 65-SERIES COMPRESSOR BLADES IN CASCADE AT LOW SPEEDS. L. Joseph Herrig, James C. Emery, and John R. Erwin. December 1951. 66p. diagrs., tabs. (NACA RM L51J16)

NACA 65-series compressor blades cambered to an isolated airfoil lift coefficient of 1.2 have been tested in a low-speed porous-wall cascade with maximum section thicknesses of 6, 8, 10, 12, and 15 percent of the chord to obtain the effect of maximum section thickness on section operating characteristics. A 10-percent-thick section tested with a trailing-edge radius of 1 and 2 percent chord was compared with data for a similar section having the usual 0.15 percent radius to determine the penalties incurred with more practical trailing edges. The low-speed operating range increases about 50 percent and the low-speed turning angle decreases 2° to 4° as the section thickness is increased from 6 percent to 15 percent chord. Sections having trailing-edge radii of 1 percent chord are recommended for practical construction.

NACA RM L52C10

USE OF AN AERODYNAMICALLY PULSED ALL-MOVABLE HORIZONTAL TAIL TO OBTAIN LONGITUDINAL CHARACTERISTICS OF ROCKET-POWERED MODELS IN FREE FLIGHT AND SOME INITIAL RESULTS FROM AN ARROW-WING-BODY-TAIL CONFIGURATION. Warren Gillespie, Jr., and Albert E. Dietz. May 1952. 31p. diagrs., photos. (NACA RM L52C10)

Data at lifting conditions from continuous longitudinal pitching motions may be obtained through use of an aerodynamic pulsing horizontal tail moving between fixed tail deflections. A description of the method and results of an initial flight test of a configuration having an arrow wing of 67.5° leading-edge sweep, and aspect ratio 1.85 with an unswept tail of aspect ratio 2.3 are presented.

NACA RM L52C13

SOME WIND-TUNNEL RESULTS OF AN INVESTIGATION OF THE FLUTTER OF SWEPTBACK- AND TRIANGULAR-WING MODELS AT MACH NUMBER 1.3. W. J. Tuovila. May 1952. 12p. diagrs., tab. (NACA RM L52C13)

Flutter tests of untapered, low-aspect-ratio, sweptback wing models and of triangular-wing models of solid magnesium, aluminum, and steel construction have been made in an intermittent supersonic wind tunnel at Mach number 1.3. Flutter data are presented for 31 untapered-wing models with 0°, 30°, 45°, and 60° sweepback and for 24 triangular-wing models. Flutter boundaries are indicated on plots of streamwise thickness ratio and aspect ratio. No attempt has been made to correlate the results with analytical developments.

NACA RM L52C28

CHORDWISE PRESSURE DISTRIBUTION AT HIGH SUBSONIC SPEEDS NEAR MIDSEMISPAN OF A TAPERED 35° SWEPTBACK WING OF ASPECT RATIO 4 HAVING NACA 65A006 AIRFOIL SECTIONS AND EQUIPPED WITH VARIOUS SPOILER AILERONS. Alexander D. Hammond and Barbara M. McMullan. June 1952. 76p. diagrs., tabs. (NACA RM L52C28)

This paper presents the chordwise-pressure distribution at the 46-percent-semispan station over a solid plug-type spoiler aileron, a fingered spoiler, and a perforated spoiler on a tapered 35° sweptback wing of aspect ratio 4 with NACA 65A006 airfoil section. The tests were made at angles of attack from 0° to 20° and at Mach numbers from 0.60 to 0.93.

NACA RM L53B26a

A COMPARISON OF TYPICAL NATIONAL GAS TURBINE ESTABLISHMENT AND NACA AXIAL-FLOW COMPRESSOR BLADE SECTIONS IN CASCADE AT LOW SPEED. A. Richard Felix and James C. Emery. May 1953. 46p. diagrs., photo., tabs. (NACA RM L53B26a)

Comparative cascade tests of the NGTE (National Gas Turbine Establishment of Great Britain) 10C4/30C50 and NACA 65-(12)10 axial-flow compressor blade sections were conducted in a 5-inch low-speed cascade tunnel at the Langley Laboratory at air-inlet angles of 30°, 45°, and 60° and a solidity of 1.0 by using the porous-wall technique. These NACA data for the NGTE 10C4/30C50 section were also compared with data from NGTE design charts for the same section. British and NACA incompressible cascade force-analysis equations are included.

NACA RM L53C09

INVESTIGATION OF THE EFFECTS OF WING AND TAIL MODIFICATIONS ON THE LOW-SPEED STABILITY CHARACTERISTICS OF A MODEL HAVING A THIN 40° SWEPT WING OF ASPECT RATIO 3.5. Joseph Weil, William C. Sleeman, Jr., and Andrew L. Byrnes, Jr. April 1953. 95p. diagrs., photos., tab. (NACA RM L53C09)

This paper presents the basic low-speed longitudinal and lateral stability characteristics of a model having a thin 40° swept wing of aspect ratio 3.5. Information is presented to show the effects of wing modifications (such as fences and leading-edge chord extensions) and changes in horizontal-tail location on the stability characteristics of the model. Longitudinal data were also obtained with an enlarged root inlet for the basic configuration and with several wing and tail modifications.

NACA RM L53C13

PRESSURE AND FORCE CHARACTERISTICS AT TRANSONIC SPEEDS OF A SUBMERGED DIVERGENT-WALLED AIR INLET ON A BODY OF REVOLUTION. John A. Braden and P. Kenneth Pierpont. May 1953. 65p. photos., diagrs., tabs. (NACA RM L53C13)

Results in terms of pressure recovery, lift, pitching moment, and external drag are presented of an investigation of a twin submerged divergent-walled inlet configuration mounted on a body of revolution. The minimum inlet area was about 16 percent of the frontal area and the diffuser had an area ratio of about 2.4/1. Data were obtained over a Mach number and angle-of-attack range from 0.6 to 1.09 and 0° to 10.6°, respectively. The results indicated that the total-pressure recovery, adversely affected by angles of attack, was inferior to a forward-located underslung scoop. Lift and pitching moments were substantially the same as for the basic body for all test conditions. External drag at high mass-flow ratios was approximately the same as for the basic body.

NACA RM L53C17

LARGE-SCALE FLIGHT MEASUREMENTS OF ZERO-LIFT DRAG AND LOW-LIFT LONGITUDINAL CHARACTERISTICS OF A DIAMOND-WING—BODY COMBINATION AT MACH NUMBERS FROM 0.725 TO 1.54. Harvey A. Wallskog and John D. Morrow. April 1953. 18p. diagrs., photo., tab. (NACA RM L53C17)

A large-scale diamond-wing—body configuration has been flown by the Langley Pilotless Aircraft Research Division at Mach numbers from 0.725 to 1.54 and Reynolds numbers, based on the wing mean aerodynamic chord, up to 35×10^6. The diamond-plan-form wing had an NACA 65A003 airfoil section, a total aspect ratio of 2.31, and a leading-edge sweep of approximately 41°. Drag-coefficient values of a 3-percent-thick 60° delta-wing configuration are shown for comparison. The results of this free-flight investigation showed that the diamond-wing configuration had lower wing-plus-interference drag up to a Mach number of 1.02 but about 17 percent greater drag above a Mach number of 1.3 than did a similar 60° delta-wing model.

NACA RM L53C18

LOW-SPEED INVESTIGATION OF THE AERODYNAMIC, CONTROL, AND HINGE-MOMENT CHARACTERISTICS OF TWO TYPES OF CONTROLS ON A DELTA-WING-FUSELAGE MODEL WITH AND WITHOUT NACELLES. William I. Scallion. May 1953. 47p. diagrs., photos., tabs. (NACA RM L53C18)

Results are presented of an investigation to determine the low-speed longitudinal control, lateral control, and hinge-moment characteristics at zero yaw of a 60° sweptback delta-wing-fuselage combination with 65A003 airfoil sections equipped with half-delta and horn-balance-type tip controls having areas of 5.2 and 10.2 percent of the wing area, respectively. Comparison is made between controls, and effects of wing-mounted nacelles on control and hinge-moment characterisitcs are presented.

NACA RM L53C23

THE EFFECT AT HIGH SUBSONIC SPEEDS OF A FLAP-TYPE AILERON ON THE CHORDWISE PRESSURE DISTRIBUTION NEAR MIDSEMISPAN OF A TAPERED 35° SWEPTBACK WING OF ASPECT RATIO 4 HAVING NACA 65A006 AIRFOIL SECTION. Alexander D. Hammond and Barbara M. Keffer. May 1953. 89p. diagrs., tab. (NACA RM L53C23)

This paper presents effects of the deflection of a flap-type aileron on the chordwise pressure distribution at the 46-percent-semispan station of a tapered 35° sweptback wing of aspect ratio 4 with an NACA 65A006 airfoil section. The tests were made at angles of attack from 0° to 20° and at Mach numbers from 0.60 to 0.95 for aileron deflections from -30° to 30°.

NACA RM L53C30

INVESTIGATION AT LOW SPEED OF THE FLOW FIELD BEHIND THE LIFTING SURFACES OF A MODEL EQUIPPED WITH A 60° TRIANGULAR WING AND A 60° TRIANGULAR CANARD TAIL. Ernest E. Newman and Jones F. Cahill. June 1953. 44p. diagrs., photos., tab. (NACA RM L53C30)

An investigation has been made at a Reynolds number of 9×10^6 and a Mach number of 0.14 of the flow field behind the lifting surfaces of a model equipped with a 60° triangular wing and a 60° triangular canard tail. Downwash, sidewash, and dynamic-pressure measurements were made through a range of angle of attack for two stations behind the wing without the canard tail, for a station behind the canard tail at the location of the leading edge of the wing mean aerodynamic chord (wing removed), and at $0.25\bar{c}$ forward of the wing trailing edge (wing in place).

NACA RM L53C31

FREE-FALL MEASUREMENTS OF THE EFFECTS OF WING-BODY INTERFERENCE ON THE TRANSONIC DRAG CHARACTERISTICS OF SWEPT-WING-SLENDER-BODY CONFIGURATIONS. Max C. Kurbjun and Jim Rogers Thompson. May 1953. 34p. diagrs., photos., tabs. (NACA RM L53C31)

The present paper contains free-fall measurements of the pressure distribution and transonic drag characteristics for a wing-body combination consisting of a body of fineness ratio 12 and a 45° sweptback wing located behind the maximum diameter of the body. The results do not confirm those reported previously (in NACA RM L7I01). Results are compared with results of previously tested models and analysis revealed that an unfavorable interference effect on the body drag due to the presence of the wing occurred at transonic speeds and did not vary appreciably with location of the wing on the body. The pressure measurements showed that the mechanism of the drag rise occurred at a lower Mach number because of the lower critical Mach number of the wing-body combination.

NACA RM L54H18a

SUMMARY OF 65-SERIES COMPRESSOR-BLADE LOW-SPEED CASCADE DATA BY USE OF THE CARPET-PLOTTING TECHNIQUE. A. Richard Felix. November 1954. 9p. diagrs. (NACA RM L54H18a)

The carpet-plotting technique is presented in this paper as a more useful and concise method of summarizing cascade data on the 65-series compressor blades given in NACA RM L51G31. Carpet plots included permit the selection of the blade camber and the design angle of attack required to fulfill a design vector diagram. Other carpet plots provide means for the prediction of off-design turning angles. Also presented are carpet plots of an isentropic pressure-rise coefficient as a function of inlet-air angle, turning angle, and entering Mach number.

DYNAMIC CORROSION IN AN IRON-STAINLESS STEEL TOROID BY SODIUM AT 900° F. Robert A. Lad. January 15, 1954. 9p. diagrs., tabs. (NACA RM E54A27)

A corrosion investigation was conducted with molten sodium blowing at a velocity of 25 feet per second in a toroid of AISI type 347 stainless steel with an insert consisting of seven Globeiron tubes in parallel at the hot zone. A 500-hour test was run at a nominal outer wall temperature of 900° F with a temperature difference between the hot and cold sections of 40° F. Chemical analysis of the toroid contents indicated attack of the stainless steel as well as the Globeiron. Metallographic examination of a section from the cold zone showed the presence of a porous mass-transfer deposit 0.001 inch thick.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1224

EFFECTS OF WING POSITION AND FUSELAGE SIZE ON THE LOW-SPEED STATIC AND ROLLING STABILITY CHARACTERISTICS OF A DELTA-WING MODEL. Alex Goodman and David F. Thomas, Jr. 1955. ii, 31p. diagrs., photos., tabs. (NACA Rept. 1224. Supersedes TN 3063)

Results are presented of an investigation made to determine the effects of wing position and fuselage size on the low-speed static and rolling stability characteristics of models having a triangular wing and vertical tail surfaces. Interference increments between the various components are evaluated, and the variation of the vertical-tail lift-curve slopes and the efficiency factors with angle of attack as affected by wing position and body size are presented. Tuft-grid pictures of the flow at the vertical tail as affected by wing-fuselage interference are also presented.

NACA Rept. 1225

DETERMINATION OF LATERAL-STABILITY DERIVATIVES AND TRANSFER-FUNCTION COEFFICIENTS FROM FREQUENCY-RESPONSE DATA FOR LATERAL MOTIONS. James J. Donegan, Samuel W. Robinson, Jr., and Ordway B. Gates, Jr. 1955. i, 19p. diagrs., tabs. (NACA Rept. 1225. Supersedes TN 3083)

A method is presented for calculating the lateral-stability derivatives and lateral transfer-function coefficients from frequency-response data for a rigid airplane. Two examples are used to illustrate the method. Accurate lateral-stability derivatives can be obtained only when accurate frequency-response data are available.

NACA Rept. 1230

GENERALIZED INDICIAL FORCES ON DEFORMING RECTANGULAR WINGS IN SUPERSONIC FLIGHT. Harvard Lomax, Franklyn B. Fuller and Loma Sluder. 1955. ii, 27p. diagrs., tab. (NACA Rept. 1230. Supersedes TN 3286)

A method is presented for determing the time-dependent flow over a rectangular wing moving with a supersonic forward speed and undergoing small vertical distortions expressible as polynomials involving spanwise and chordwise distances. Results are expressed in terms of generalized indicial forces. Numerical results for Mach numbers of 1.1 and 1.2 are given for polynomials of the first and fifth degree in the chordwise and spanwise directions, respectively, on a wing of aspect ratio 4.

NACA Rept. 1235

STANDARD ATMOSPHERE—TABLES AND DATA FOR ALTITUDES TO 65,800 FEET. International Civil Aviation Organization, Montreal, Canada and Langley Aeronautical Laboratory, Langley Field, Va. 1955, v, 114p. tabs. (NACA Rept. 1235. Supersedes TN 3182; Rept. 218)

The physical constants and basic equations defining the International Civil Aviation Organization (ICAO) Standard Atmosphere are presented together with tables and diagrams of the properties of the ICAO Standard Atmosphere computed by the National Advisory Committee for Aeronautics in both metric and English units for altitudes from -5,000 meters to 20,000 meters and from -16,500 feet to 65,800 feet.

NACA Rept. 1237

A FLIGHT EVALUATION OF THE LONGITUDINAL STABILITY CHARACTERISTICS ASSOCIATED WITH THE PITCH-UP OF A SWEPT-WING AIRPLANE IN MANEUVERING FLIGHT AT TRANSONIC SPEEDS. Seth B. Anderson and Richard S. Bray. 1955. ii, 12p. diagrs., photo., tab. (NACA Rept. 1237. Supersedes RM A51I12)

Flight measurements on a swept-wing jet aircraft showed that the pitch-up encountered in a wind-up turn at transonic Mach numbers was due principally to an unstable break in the wing pitching moment associated with flow separation near the wing tip. The pitch-up encountered in slowing down in a dive-recovery maneuver was due chiefly to a reduction in wing-fuselage stability. An increase in down load for the horizontal tail was indicated with increase in Mach number for normal force-coefficient values in excess of approximately 0.2.

NACA RM L55H04a

SUMMARY OF LOCATIONS AND EXTENTS OF TURBULENT AREAS ENCOUNTERED DURING FLIGHT INVESTIGATIONS OF THE JET STREAM FROM OCTOBER 1953 TO MAY 1954 AND NOVEMBER 1954 TO JULY 1955. Mary W. Fetner. April 1956. 10p. tab. (NACA RM L55H04a)

The locations and extents of turbulent areas encountered during flights of a Boeing B-47B airplane engaged in an investigation of the jet stream and the Sierra Mountain Wave are presented. The data were obtained from NACA VGH time-history records in cooperation with the Air Force Cambridge Research Center.

NACA TM 1392

ON THE BUCKLING OF BARS AND PLATES IN THE PLASTIC RANGE. PART II. (Over het knikvraagstuk in het plastische gebied bij staven en platen. (Deel)). J. P. Benthem. March 1956. 79p. diagrs., tabs. (NACA TM 1392. Trans. of Nationaal Luchtvaartlaboratorium, Amsterdam, Rapport S. 423, Jan. 1954)

A review is made of existing literature concerning comparison with experiment of various theoretical formulas for buckling of plates in the plastic region. The significance and relative merits of various theories are discussed.

NACA TN 3271

THERMODYNAMIC PROPERTIES OF GASEOUS NITROGEN. Harold W. Woolley, National Bureau of Standards. March 1956. 114p. diagrs., tabs. (NACA TN 3271)

The NBS-NACA tables of thermal properties of gaseous nitrogen are grouped together in this report for convenient use. They include the thermodynamic functions for the gas, both real and ideal, the transport properties for the gas, and the vapor pressure of the liquid and the solid. The tables are in dimensionless form and conversion factors to frequently used units are given. Deviation plots or tables indicating the agreement or discordance of the experimental data are included.

NACA TN 3543

SOME EFFECTS OF FUSELAGE FLEXIBILITY ON LONGITUDINAL STABILITY AND CONTROL. Bernard B. Klawans and Harold I. Johnson. April 1956. 42p. diagrs., tab. (NACA TN 3543)

Some effects of fuselage flexibility on longitudinal stability and control of a large high-speed airplane were determined by application of a semirigid analysis. The dynamic characteristics are examined by studying the period and damping of the fuselage and airplane short-period longitudinal modes of oscillation. The static characteristics are examined by studying the longitudinal stability margins and the elevator-control deflections required for balance in straight or steady maneuvering flight.

NACA TN 3597

ANALYSIS OF A VANE-CONTROLLED GUST-ALLEVIATION SYSTEM. Robert W. Boucher and Christopher C. Kraft, Jr. April 1956. 45p. diagrs., tabs. (NACA TN 3597)

A theoretical study, using an electronic analog computer, is made of the response to step gusts of an airplane equipped with a system in which modified wing flaps and a modified elevator are operated to reduce accelerations in rough air. These surfaces are actuated by an automatic control system in response to the indications of an angle-of-attack vane. The effect of interconnection of the flap operating mechanism with the pilot's control system is also included.

NACA TN 3609

LINEARIZED LIFTING-SURFACE AND LIFTING-LINE EVALUATIONS OF SIDEWASH BEHIND ROLLING TRIANGULAR WINGS AT SUPERSONIC SPEEDS. Percy J. Bobbitt. March 1956. 63p. diagrs. (NACA TN 3609)

The sidewash in the vertical plane of symmetry behind steady-rolling triangular wings traveling at supersonic speeds has been derived by use of both linearized lifting-surface and lifting-line methods. The lifting-surface results are limited by the condition that the wing leading edges must be subsonic. Variations of the sidewash with vertical and longitudinal distances are presented in graphical form for a number of combinations of Mach number and leading-edge sweep. Sidewash computed by the lifting-line method showed good agreement with lifting-surface results except close behind the trailing edge when the leading edge approached the sonic condition. An illustrative calculation has been made of the force induced by the sidewash behind a triangular wing on a vertical tail located in various longitudinal positions. The approximate lifting-line expression may be used to compute the sidewash behind rolling wings of arbitrary plan form and span loading.

NACA TN 3611

ANALYSIS OF A SPIN AND RECOVERY FROM TIME HISTORIES OF ATTITUDES AND VELOCITIES AS DETERMINED FOR A DYNAMIC MODEL OF A CONTEMPORARY FIGHTER AIRPLANE IN THE FREE-SPINNING TUNNEL. Stanley H. Scher. April 1956. 54p. diagrs., photos., tabs. (NACA TN 3611)

A technique for determining time histories of the attitudes and velocities of free-spinning-tunnel models during spins and recoveries is presented and applied to a model representative of a contemporary fighter airplane. One spin and the recovery therefrom are investigated, and discussions as to the nature of the spin and recovery motions and some factors affecting them are presented along with the time histories.

NACA TN 3612

INITIAL RESULTS OF A FLIGHT INVESTIGATION OF A GUST-ALLEVIATION SYSTEM. Christopher C. Kraft, Jr. April 1956. 19p. diagrs., photos., tabs. (NACA TN 3612)

A flight investigation of a gust-alleviation system designed to improve passenger comfort in flight through turbulent air has been recently initiated. The system is designed to maintain constant lift in rough air by means of trailing-edge wing flaps operated by an automatic control system which is controlled by signals from an angle-of-attack vane located at the nose of the airplane. The gust-alleviation system is at least capable of reducing the normal accelerations due to gusts by 50 percent in the range of the natural frequency of the airplane.

NACA TN 3624

INVESTIGATION OF THE USE OF THE THERMAL DECOMPOSITION OF NITROUS OXIDE TO PRODUCE HYPERSONIC FLOW OF A GAS CLOSLY RESEMBLING AIR. Alexander P. Sabol and John S. Evans. March 1956. 36p. diagrs., tabs. (NACA TN 3624)

A method is presented for producing hypersonic flow in a wind tunnel by using the hot gaseous products obtained from the thermal decomposition of nitrous oxide. Comparable experimental results were obtained when pressures in a divergent conical hypersonic nozzle operated by this method at a Mach number of about 7 were compared with those of heated air. The design of the reactor used to operate the nozzle was based on results of constant-volume and constant-pressure decomposition tests which are described. Decomposition temperatures up to 1859° K (3346° R) at pressures up to 1930 atmospheres were obtained for the constant-volume process, whereas theory indicated a temperature of 2507° K (4510° R). Temperatures up to 1726° K (3107° R) at pressures up to 70 atmospheres were obtained for the constant-pressure process, whereas theory indicated a temperature of 2165° K (3898° R).

NACA TN 3635

ANALYTICAL STUDY OF MODIFICATIONS TO THE AUTOPILOT OF A FIGHTER AIRPLANE IN ORDER TO REDUCE THE RESPONSE TO SIDE GUSTS. Charles W. Mathews and James J. Adams. March 1956. 35p. diagrs., tabs. (NACA TN 3635)

Results of some calculations of the roll and yaw responses to side gusts of an airplane-autopilot system are presented. Course responses to lateral-steering commands are also presented. A comparison is made between the basic autopilot and one in which the rudder channel is modified specifically in order to alleviate the effects of side gusts. The results indicate that, through fairly minor modifications to the rudder channel, the response to side gusts can be noticeably reduced.

NACA TN 3645

WIND-TUNNEL INVESTIGATION OF EFFECTS OF FUSELAGE CROSS-SECTIONAL SHAPE, FUSELAGE BEND, AND VERTICAL-TAIL SIZE ON DIRECTIONAL CHARACTERISTICS OF NONOVERLAP-TYPE HELICOPTER FUSELAGE MODELS WITHOUT ROTORS. James L. Williams. March 1956. 39p. diagrs., photos. (NACA TN 3645)

This paper presents the results of a low-speed wind-tunnel investigation to determine the effect of fuselage cross section, fuselage bend, and vertical tail size on the directional stability characteristics of nonoverlap-type helicopter fuselage models.

NACA TN 3660

INVESTIGATION OF THE Ni_3Al PHASE OF NICKEL-ALUMINUM ALLOYS. Edward M. Grala. April 1956. 24p. diagrs., photos., tabs. (NACA TN 3660)

The stoichiometric Ni_3Al intermetallic had an as-cast room-temperature tensile strength of 28,650 psi with 1.0-percent elongation; after homogenization at 1800° F this strength decreased to 20,350 psi with 0.2-percent elongation. A 14-percent-aluminum alloy in the same phase field had better tensile properties than the stoichiometric composition, with an as-cast room-temperature tensile strength of 39,250 psi, and a homogenized tensile strength of 32,100 psi; at 1500° F the tensile strength was 19,600 psi. The stress-rupture strength was evaluated at 1500°, 1600°, and 1700° F for the 14-percent-aluminum alloy; the 100-hour rupture strength was interpolated as 8,600 psi at 1500° F. The stoichiometric Ni_3Al had no hot-workability and only moderate impact strength.

NACA TN 3661

SELF SHIELDING IN RECTANGULAR AND CYLINDRICAL GEOMETRIES. Harold Schneider, Paul G. Saper, and Charles F. Kadow. April 1956. 40p. diagrs., tabs. (NACA TN 3661)

The steady-state diffusion approximation and the P_3 approximation of transport theory have been applied for a comparison of the neutron flux distributions and self-shielding factors for multiregion cells of rectangular and cylindrical geometries. These cells represent a given arrangement of moderator, fuel, and cladding; usually considered to be homogeneous. The effects of chemical binding in the water region of the cells were also studied and the results were compared with the cases where chemical binding was neglected. An electromechanical differential analyzer was used to solve the flux equations.

NACA TN 3663

DISCHARGE COEFFICIENTS FOR COMBUSTOR-LINER AIR-ENTRY HOLES. I - CIRCULAR HOLES WITH PARALLEL FLOW. Ralph T. Dittrich and Charles C. Graves. April 1956. 39p. diagrs. (NACA TN 3663)

An experimental investigation was conducted to determine the effects of hole diameter, wall thickness at hole, duct height, parallel-flow velocity, pressure ratio, boundary-layer thickness, and static-pressure level on the discharge coefficient for circular holes having flow parallel to the plane of the hole. Discharge coefficients, corrected for pressure-ratio effects, were correlated with a flow parameter. Within the ranges investigated, only the parallel-flow velocity and the static-pressure ratio across the hole had large effects on discharge coefficient.

NACA TN 3665

PERFORMANCE AND OPERATIONAL STUDIES OF A FULL-SCALE JET-ENGINE THRUST REVERSER. Robert C. Kohl. April 1956. 38p. diagrs., photo. (NACA TN 3665)

An axial-flow turbojet engine equipped with a hemispherical target thrust reverser was pylon-mounted beneath the wing of a cargo airplane. A maximum reverse-thrust ratio of 58 percent was produced. Reingestion of the reversed hot gases into the engine inlet overheated the engine and reduced the reverse-thrust ratio by as much as 25 percentage points. Taxi tests indicated that ground speeds up to 62 knots were required to overcome reingestion. Temperatures of nearly 400° F above ambient were measured on a simulated wing surface above the thrust reverser. The maximum rate of temperature rise was 28° F per second.

FORMULAE AND APPROXIMATIONS FOR AERODYNAMIC HEATING RATES IN HIGH SPEED FLIGHT. R. J. Monaghan. October 1955. 53p. diagrs. (RAE Tech. Note Aero 2407)

Formulas are based on the "intermediate enthalpy" approximation which has given good agreement with theoretical and experimental evidence. In the general flight case they could be used in conjunction with an analog computer or a step-by-step method of integration to predict the variations of heat flow and skin temperature with time. In the restricted case of flight at constant altitude and Mach number, simple analytical methods and results are given which include the effects of radiation and can be applied to "thick" as well as "thin" skins.

FLOW SEPARATION IN THREE DIMENSIONS. E. C. Maskell. November 1955. 20p. diagrs. (RAE Aero 2565)

A generalized concept of flow separation is presented, and the conditions in the neighborhood of a line of separation are deduced. The resulting flow is shown to be composed of two basic elements (i) the free vortex layer and (ii) the bubble, each of which is identified by a characteristics pattern formed in the solid surface by the family of limiting streamlines. From the results of the analysis the physical structures of possible three-dimensional flows are readily inferred.

SOME PROPERTIES OF CURVED PLANFORMS FOR SWEPTBACK WINGS AT SUBSONIC AND SUPERSONIC SPEEDS. G. G. Brebner and W. T. Lord. November 1955. 17p. diagrs. (RAE Tech. Note Aero 2417)

Entirely independent considerations of spanwise C_L distribution at subsonic speeds and of zero-lift wave drag at supersonic speeds suggest that curved plan forms may have advantages over conventional straight-edged plan forms for sweptback wings. Examples are constructed in which curved wings with nearly constant spanwise C_L distribution at subsonic speeds are shown to have theoretical zero-lift wave drags which are much more plausible than those calculated for comparable straight-edged wings over a wide range of Mach number.

SUPERSONIC FLOW PAST QUASI-CYLINDRICAL BODIES OF ALMOST CIRCULAR CROSS-SECTION. D. G. Randall. November 1955. 26p. diagrs., tabs. (RAE Tech.Note Aero 2404)

The supersonic flow over bodies for which the surface boundary condition may be satisfied on a circular cylinder is considered. The method is based on the linearized small-perturbation theory of supersonic flow. The disturbance velocity potential is obtained as a Fourier series each term of which contains a certain basic function and the first 11 of these functions are evaluated. The pressure distribution and wave drag have been calculated for some bodies consisting of circular cylinders surmounted by canopies. An extension of the method to solve certain wing-body interference problems is also described, but no numerical results have yet been obtained.

Royal Aircraft Establishment (Gt. Brit.)
MEASUREMENT OF THE CROSS FLOW AROUND AN INCLINED BODY AT A MACH NUMBER OF 1.91. D. J. Raney. January 1955. 29p. diagrs., photos. (RAE Tech. Note Aero 2357)

Measurements have been made in the upper (leeward) half of the cross flow plane of the upwash and sidewash around a body of revolution at 5 and 13 calibers downstream of the nose. Diagrams are given showing the resultant crossflow distribution at these two positions. At the rear position the crossflow caused by the vortex pair shed from the body, and their images has been derived by subtracting the incompressible potential crossflow around a two-dimensional circular cylinder from the measured crossflow. A corresponding theoretical crossflow due to the vortices has been estimated assuming infinitely long subsonic vortices of constant strength. The absolute magnitudes of the derived and theoretical crossflows could not be compared directly as the vortex circulation could not be reliably estimated. However, the direction and relative magnitude throughout the flow field of these derived and theoretical crossflows are in good agreement, except close to the vortices and at positions where very large crossflows existed. Experimental accuracy was inadequate at these positions. Results of these tests do not explain recent normal force measurements which showed a reduction in slope near 10° incidence of the curve of normal force on a control mounted on a body, due to the presence of the body.

SOME TESTS OF THE SPREAD OF VELOCITY IN A COLD JET DISCHARGING WITH EXCESS PRESSURE FROM A SONIC EXIT INTO STILL AIR. J. Seddon and L. Haverty. November 1955. 16p. diagrs., photos. (RAE Tech.Note Aero 2400)

The spread of the half-velocity circle in a jet discharging with excess pressure from a length of parallel pipe into still air has been examined over the range 40 to 200 diameters from the exit. Jet pressure ratios (outside static pressure ÷ jet total pressure) were from 0.479 to 0.042, corresponding to isentropic Mach numbers from 1.08 to 2.72. It is found that rates of spread are not greatly different from that for a subsonic jet. The effective exit of an underexpanded jet is, however, displaced some distance downstream of the actual exit. For a jet of isentropic Mach number 1.51, the effective exit position is about 8 diameters downstream and the half-velocity circles lie on a cone of semiangle 5.7^{o} from the center of the effective exit.

AEROELASTIC NUMBER. S. Neumark, A. S. Taylor, and H. H. B. M. Thomas. August 1955. 11p. (RAE Tech.Note Aero 2389)

A proposal is made for the introduction of a non-dimensional aeroelastic number (ϵ) which, used in conjunction with Mach number and Reynolds number, permits the development of a consistently non-dimensionalized expression for the static margin (K_n) of an aircraft in the case where the aerodynamic coefficients are dependent on speed through compressibility, viscosity and aeroelastic distortion effects. Although ϵ may not appear explicitly in the corresponding expressions for other stability and control criteria, such as the maneuver margin (H_m), the various derivatives appearing in such expressions will, like those occurring in K_n, usually be functions of ϵ. Accordingly, the general use of the aeroelastic number in the presentation of the results of aeroelastic calculations and measurements is advocated.

Royal Aircraft Establishment (Gt. Brit.)
THE CALCULATION OF THE SPANWISE LOADING OF SWEPTBACK WINGS WITH FLAPS OR ALL-MOVING TIPS AT SUBSONIC SPEEDS. G. G. Brebner and D. A. Lemaire. September 1955. 54p. diagrs., tabs. (RAE Aero 2553)

The results of some electric tank tests by Duquenne and Grandjean on wings of 45° sweepback with trailing edge flaps have been analyzed to provide the basis for a method of calculating the spanwise loading. The analysis yielded information about the effect of sweep on the equivalent incidence of a section with flap, on the downwash factor and on the spanwise loading distribution with an incidence discontinuity. Interpolation formulas are developed to extend the results to wings of any sweep and flap span, and thus a complete calculation method is presented for the spanwise loading with this type of control. The calculation method is tentatively extended to a wing with all-moving tip control, and the results compared with those of Thomas and Mangler. There is a marked discrepancy between the two calculations. Further electric tank tests to fill this and other gaps are suggested.

Royal Aircraft Establishment (Gt. Brit.)
PREPARATION AND PROPERTIES OF HIGH TEMPERATURE PYROLYTIC CARBON. A. R. G. Brown. June 1955. 59p. diagrs., photos., tabs. (RAE Met. 87)

A method for preparing massive specimens of carbon by the breakdown of hydrocarbon gases at various temperatures and subatmospheric pressures is described. The rate of deposition, density, electrical resistivity, and thermal conductivity of the deposits are found to be dependent on temperature of deposition. For deposits produced at 1800° C the density is 1.35 g/cm^3, the electrical resistivity 22 x 10^{-6} ohm cms, and thermal conductivity 0.06 g cal cm/cm^2 °C sec; the corresponding values for material formed at 2100° C are 2.23 g/cm^3, 200 x 10^{-6} ohm cms, and 1.3 g cal cm/cm^2 °C sec. The structure of the deposits is of layer planes of hexagonally arranged carbon atoms lying parallel to the surface of the original substrate, but otherwise randomly oriented.

Royal Aircraft Establishment (Gt. Brit.)
SEBALKYD DOUGHS. A. C. Cornwell. October 1955. 11p. tabs. (RAE Tech.Note Chem.1265)

A gap-filling material which will expand and harden in situ without external heating has been developed for cases where the cavity to be filled renders the normal technique of pouring or injection difficult. By loading the foam with inorganic filler and using an alkyd resin with an acid number of 5-25, a dough-like material can be made which has a working life of 15-60 minutes and which will expand 2-3 times in a few hours after mixing, giving a material with a density ranging from 25-65 lb/cu ft. After mixing, the dough can be frozen by immersion in liquid air or powdered solid carbon dioxide. The resulting hard solid can be kept in the freezing mixture for a few days and will only expand and complete its cure when allowed to warm up.

THE EFFECT OF SODIUM STANNATE AND OTHER STABILIZERS ON THE PHOTOLYTIC DECOMPOSITION OF H.T.P. (85 PERCENT W/W HYDROGEN PEROXIDE). D. Sutton. December 1955. 13p. diagrs. (RAE Tech.Note RPD 137)

The photolytic decomposition of 85 percent w/w hydrogen peroxide in the presence of small amounts of various stabilizers has been studied. Sodium stannate was found to be the only stabilizer which appreciably reduced the rate of the photolytically induced decomposition. It is inferred from this that sodium stannate is effective as a radical chain terminator probably by adsorption of free radicals on the surface of the colloidal hydrated stannic oxide which is known to be formed when sodium stannate is added to strong solutions of hydrogen peroxide. The rates of decomposition of 85 percent w/w hydrogen peroxide solutions containing small amounts of catalytic ions and stabilizers have also been studied.

National Gas Turbine Establishment (Gt. Brit.) MIXING AND THE JET FLAP. B. S. Stratford and N. A. Dimmock. October 1955. 45p. diagrs., photos., tabs. (NGTE Memo.M.250)

The "Jet Flap" is a means for producing high lift on aircraft. One of the main problems associated with the jet flap concerns the differences in thrust between idealized theory and experimental results. These differences are attributable to the mixing (with the surrounding flow) of the thin two-dimensional jet, this mixing occurring very close to the airfoil. To a first approximation the effect of the mixing on the thrust may be calculated from a simple formula, derivable from first principles. Second order effects, which can be significant, may be considered quantitatively.

COMPLETE REPRESENTATION OF THE TURBULENT VELOCITY DISTRIBUTION IN SMOOTH PIPES. (Vollständige Darstellung der turbulenten Geschwindigkeits-verteilung in glatten Leitungen). H. Reichardt. February 1956. 23p. diagrs. (Trans. from Zeitschrift für angewandte Mathematik und Mechanik, v. 31, no. 7, July 1951, p. 208-219)

On the basis of experimental investigations of turbulent exchange of momentum, a formula has been derived for the velocity of turbulent flows in pipes and channels. This formula gives a complete representation of the velocity distribution over a radius, that is, it is approximately valid for the immediate vicinity of the wall as well as for the core of the flow cross section.

FLIGHT DETERMINATION OF THE EFFECTS OF RUDDER-PEDAL-FORCE CHARACTERISTICS ON THE AIMING ERROR IN AZIMUTH OF A CONVENTIONAL FIGHTER AIRPLANE. Lee Winograd and Rudolph D. Van Dyke, Jr. July 5, 1950. 32p. diagrs., photos., tab. (NACA RM A50D06)

The effect on pilot-azimuth tracking ability of a change in the rudder-pedal-force characteristics of a conventional fighter airplane was studied. Simulated gunnery runs were made on both stationary and moving targets with the normal rudder and with a rudder modified to produce approximately zero pedal-force variation with sideslip. The effect of the modification on mean azimuth tracking error was insignificant, but it was fatiguing to fly the airplane for any length of time.

NACA RM A51C19

AN ANALYSIS OF THE EFFECTS OF AEROELASTICITY ON STATIC LONGITUDINAL STABILITY AND CONTROL OF A SWEPT-BACK-WING AIRPLANE. Richard B. Skoog. August 1951. 45p. diagrs. (NACA RM A51C19)

A theoretical analysis of the effects of aeroelasticity on the stick-fixed static longitudinal stability and elevator angle required for balance of an airplane is presented together with calculated effects for a swept-wing bomber of relatively high flexibility. Although large changes in stability due to certain parameters are indicated for the example airplane, the overall stability change after considering all parameters was quite small, compared to the individual effects, due to the counterbalancing of wing and tail contributions. The effect of flexibility on longitudinal control for the example airplane was found to be of little real importance.

NACA RM A51D27

CHARACTERISTICS THROUGHOUT THE SUBSONIC SPEED RANGE OF A PLANE WING AND OF A CAMBERED AND TWISTED WING, BOTH HAVING 45° OF SWEEPBACK. Ben H. Johnson, Jr., and Harry H. Shibata. July 1951. 122p. diagrs., photos. (NACA RM A51D27)

Presented in this report are results of tests at Mach numbers from 0.25 to 0.94 of two 45° sweptback wings of identical plan form. The plane wing had NACA 64A010 sections normal to the quarter-chord line and the cambered and twisted wing had NACA 64A810, a = 0.8 modified sections normal to the quarter-chord line, and 8.7° of washout at the tip. At Mach numbers between 0.70 and 0.94, the maximum Reynolds number was 2,000,000 and at a Mach number of 0.25, the maximum Reynolds number was 10,000,000. The effects of the addition of a fuselage, of chordwise fences, and of surface roughness were also investigated.

NACA RM A52D01

AN INVESTIGATION THROUGHOUT THE SUBSONIC SPEED RANGE OF A FULL-SPAN AND A SEMI-SPAN MODEL OF A PLANE WING AND OF A CAMBERED AND TWISTED WING, ALL HAVING 45° OF SWEEPBACK. Harry H. Shibata, Angelo Bandettini, and Joseph Cleary. June 1952. 65p. diagrs., photos. (NACA RM A52D01)

This report presents results of tests of full-span and semispan models at Mach numbers from 0.25 to 0.92 of two 45° sweptback wings of identical plan form. The plane wing had NACA 64A010 sections normal to the quarter-chord line and the cambered and twisted wing had NACA 64A810, a = 0.8 modified sections normal to the quarter-chord line, and 9.4° of washout at the tip. The test Reynolds number was varied from 1,000,000 to 10,000,000 at a Mach number of 0.25, and the Mach number was varied from 0.25 to 0.92 at constant Reynolds numbers of 1,000,000 and 2,000,000. In addition, the full-span model was tested throughout the same Mach number range at Reynolds numbers varying from 2,000,000 to 4,900,000. The effect of surface roughness was also investigated.

NACA RM A53D14

THE LOW-SPEED LIFT AND DRAG CHARACTERISTICS OF A SERIES OF AIRPLANE MODELS HAVING TRIANGULAR OR MODIFIED TRIANGULAR WINGS. David Graham. June 1953. 49p. diagrs., photo., tabs. (NACA RM A53D14)

Three triangular wings of aspect ratios 2, 3, and 4 and two modified triangular wings of aspect ratio 2 having taper ratios of 0.20 and 0.33 were each tested in combination with a high-fineness-ratio fuselage, a triangular vertical tail, and an unswept, all-movable horizontal tail. The tests were conducted in the Ames 40- by 80-foot wind tunnel at Reynolds numbers from approximately 11×10^6 to 15×10^6. The experimental lift and drag characteristics are compared with existing theory. The relative merits of the models with respect to wing loading attainable at given landing conditions are investigated.

NACA RM A53D21

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF AN AIRPLANE CONFIGURATION WITH A VARIABLE-INCIDENCE TRIANGULAR WING AND AN ALL-MOVABLE HORIZONTAL TAIL. David G. Koenig. June 1953. 42p. diagrs., photo., tabs. (NACA RM A53D21)

Force tests were made for various wing incidences with and without the horizontal tail. Characteristics at zero sideslip for four wing incidences were obtained with the tail off and with the tail located at each of three vertical positions. Characteristics of the model in sideslip were obtained with the wing at 10° incidence for two combinations of flap and horizontal-tail settings. The average Reynolds number based on the mean aerodynamic chord was 14.7 million, and the Mach number was 0.13.

NACA RM E9K30

EXPERIMENTAL INVESTIGATION OF THRUST AUGMENTATION OF 4000-POUND-THRUST AXIAL-FLOW-TYPE TURBOJET ENGINE BY INTERSTAGE INJECTION OF WATER-ALCOHOL MIXTURES IN COMPRESSOR. John H. Povolny, James W. Useller, and Louis J. Chelko. April 6, 1950. 42p. diagrs., photos., tab. (NACA RM E9K30)

Experimental thrust-augmentation investigation of 4000-pound-thrust axial-flow-type turbojet engine by interstage injection of water-alcohol mixtures in the compressor was conducted at sea-level, zero-ram conditions. The number, size, and arrangement of interstage nozzles were varied to produce satisfactory augmentation system of minimum complication. Four water-alcohol mixtures with varying alcohol concentration were investigated. An augmented thrust ratio of 1.22 was obtained with injection of 6.5 pounds per second of water-alcohol mixture for a corrected engine inlet-air temperature of 80° F when using a simple injection system, which introduced no loss in normal thrust.

NACA RM E50D17

EXPERIMENTAL INVESTIGATION OF THRUST AUGMENTATION OF 4000-POUND-THRUST CENTRIFUGAL-FLOW-TYPE TURBOJET ENGINE BY BLEEDOFF. William L. Jones and Louis J. Bogdan. July 3, 1950. 30p. diagrs., photo. (NACA RM E50D17)

Thrust augmentation by bleedoff was investigated at zero flight-speed, sea-level conditions on a 4000-pound-thrust centrifugal-flow-type turbojet engine. In the bleedoff cycle, the secondary combustion air was bled off from the combustion chambers and ducted into an auxiliary combustion chamber where it was heated to a high temperature and discharged through an auxiliary nozzle. Augmented thrust of 1.8 times the normal thrust was obtained by this method with a total liquid flow of about 13 times the unaugmented fuel flow.

#NACA RM E51C21

NACA RM E53D15

CARBON DEPOSITION OBTAINED WITH MIL-F-5624A FUELS IN A SINGLE COMBUSTOR AND IN THREE FULL-SCALE ENGINES. Jerrold D. Wear. June 1954. 20p. diagrs., photo., tabs. (NACA RM E53D15)

Investigations were conducted in a full-scale single turbojet combustor and in three full-scale engines with several MIL-F-5624A grade JP-3 and JP-4 fuels. Fuels that gave an increase in carbon deposition in the single combustor also gave an increase in the corresponding full-scale engine. Fuels producing deposits in excess of 7 to 9 grams in the single combustor (1) operated satisfactorily with respect to combustor deposit in the corresponding full-scale engine, (2) caused marginal operation in one of the two additional full-scale engines, and (3) caused excessive exhaust smoke in both the additional full-scale engines.

NACA RM E53E18

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. XIII - ENDURANCE EVALUATION OF SEVERAL PROTECTIVE COATINGS APPLIED TO TURBINE BLADES OF NONSTRATEGIC STEELS. Edward R. Bartoo and John L. Clure. July 1953. 40p. photos., diagrs., tabs. (NACA RM E53E18)

Four types of protective coatings (ceramic, nickel, Nicrobraz, and aluminized) were applied to 20 air-cooled turbine blades of either SAE 4130 or Timken 17-22A(S) steel and endurance-tested in a turbojet engine at maximum rated speed and turbine inlet temperature. Coolant-flow ratios between 0.030 and 0.048 were employed. Ceramic, aluminized, Nicrobraz, and a combination of nickel and Nicrobraz coatings each provided corrosion and erosion protection to at least one blade for periods of operation totaling 100 hours or more.

NACA RM L8D16

FREE-FLIGHT INVESTIGATION OF THE ROLLING EFFECTIVENESS OF SEVERAL DELTA WING - AILERON CONFIGURATIONS AT TRANSONIC AND SUPERSONIC SPEEDS. Carl A. Sandahl. August 27, 1948. 19p. diagrs., photos., tab. (NACA RM L8D16)

The rolling-effectiveness characteristics of several delta-wing—aileron configurations, obtained by means of rocket-propelled test vehicles in free flight at transonic and supersonic speeds, are presented. The experimental results are compared with calculated results from methods based on the linearized supersonic-flow equations.

NACA RM L9D12

EFFECTS OF SOME AIRFOIL-SECTION VARIATIONS ON WING-AILERON ROLLING EFFECTIVENESS AND DRAG AS DETERMINED IN FREE FLIGHT AT TRANSONIC AND SUPERSONIC SPEEDS. Carl A. Sandahl, William M. Bland, Jr., and H. Kurt Strass. July 22, 1949. 29p. diagrs., photos., tabs. (NACA RM L9D12)

An experimental investigation has been made in free flight of the rolling effectiveness of plain ailerons in conjunction with wings employing several airfoil sections having 0° and 45° sweepback. The total drag of the test vehicles was also obtained.

NACA RM L50C01

WING-DROPPING CHARACTERISTICS OF SOME STRAIGHT AND SWEPT WINGS AT TRANSONIC SPEEDS AS DETERMINED WITH ROCKET-POWERED MODELS. David G. Stone. May 26, 1950. 12p. diagrs., tab. (NACA RM L50C01)

Lateral-trim change or wing dropping has occurred on several rocket-powered models used in roll investigations at transonic speeds. The wing configurations investigated show the effects of airfoil section, aspect ratio, and sweepback on wing dropping.

NACA RM L50D17

ROLLING EFFECTIVENESS OF A THIN TAPERED WING HAVING PARTIAL-SPAN AILERONS AS DETERMINED BY ROCKET-POWERED TEST VEHICLES. Carl A. Sandahl and H. Kurt Strass. May 23, 1950. 12p. diagrs., photo. (NACA RM L50D17)

The rolling effectiveness of partial-span plain ailerons on an essentially unswept wing having a thickness ratio of 0.045, a taper ratio of 0.4, and an aspect ratio of 2.91 has been determined by means of rocket-powered test vehicles. Good agreement was obtained with theoretical results from NACA TN 1890 which considers the effects of wing elasticity.

NACA RM L50D26

LARGE-SCALE FLIGHT MEASUREMENTS OF ZERO-LIFT DRAG AT MACH NUMBERS FROM 0.86 TO 1.5 OF A WING-BODY COMBINATION HAVING A 60° TRIANGULAR WING WITH NACA 65A003 SECTIONS. Robert L. Nelson. June 1, 1950. 10p. diagrs., photos., tab. (NACA RM L50D26)

Flight tests were made at high-subsonic and supersonic speeds and at high Reynolds numbers to determine the zero-lift drag of a fin-stabilized body and a wing-body configuration. The 60° triangular wing had NACA 65A003 airfoil sections. The body was parabolic in profile, had a fineness ratio of 10 and a ratio of body frontal area to wing area of 0.0306.

NACA RM L51C22

COMPARISONS OF THE EFFECTIVENESS AND HINGE MOMENTS OF ALL-MOVABLE DELTA AND FLAP-TYPE CONTROLS ON VARIOUS WINGS. David G. Stone. April 19, 1951. 13p. diagrs. (NACA RM L51C22)

A comparative evaluation was made for all-movable delta and flap-type controls on several wing plan forms. Comparison of these experimental results from various test facilities shows the effectiveness on various wing plan forms and an evaluation of hinge-moment characteristics of all-movable delta controls, swept trailing-edge flap, and straight trailing-edge flap-type controls.

NACA RM L51D13

AERODYNAMIC CHARACTERISTICS OF FOUR WINGS OF SWEEPBACK ANGLES 0°, 35°, 45°, AND 60°, NACA 65A006 AIRFOIL SECTION, ASPECT RATIO 4, AND TAPER RATIO 0.6 IN COMBINATION WITH A FUSELAGE AT HIGH SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. Arvo A. Luoma. June 6, 1951. 59p. diagrs., photo., tab. (NACA RM L51D13)

Aerodynamic characteristics of a series of swept-back wings mounted on a common fuselage without tail surfaces at subsonic Mach numbers up to approximately 0.95 and at a Mach number of 1.2 are presented. All the wings had NACA 65A006 airfoil sections, an area of 1 square foot, an aspect ratio of 4, and a taper ratio of 0.6.

NACA RM L51D18a

SOME EFFECTS OF SPANWISE AILERON LOCATION AND WING STRUCTURAL RIGIDITY ON THE ROLLING EFFECTIVENESS OF 0.3-CHORD FLAP-TYPE AILERONS ON A TAPERED WING HAVING 63° SWEEPBACK AT THE LEADING EDGE AND NACA 64A005 AIRFOIL SECTIONS. H. Kurt Strass, E. M. Fields, and Eugene D. Schult. June 1951. 25p. diagrs., photo., tab. (NACA RM L51D18a)

This paper presents some effects of aileron spanwise location and wing structural rigidity on the rolling power of 0.3-chord plain, flap-type ailerons on a wing with a taper ratio of 0.25, aspect ratio of 3.5, and swept back 63° at the leading edge. The results show that for rigid wings the aileron spanwise location is an important consideration, with the maximum rolling effectiveness per unit span occurring at approximately midexposed span. The large effect of wing flexibility on rolling effectiveness for this wing is demonstrated by the fact that for solid aluminum alloy construction the loss of control effectiveness of an outboard 0.50-semispan aileron exceeds 30 percent of the rigid-wing value at $M \approx 1.4$.

NACA RM L51D25

SOME EFFECTS OF FUSELAGE INTERFERENCE, WING INTERFERENCE AND SWEEPBACK ON THE DAMPING IN ROLL OF UNTAPERED WINGS AS DETERMINED BY TECHNIQUES EMPLOYING ROCKET-PROPELLED VEHICLES. William M. Bland, Jr., and Albert E. Dietz. October 1951. 27p. diagrs., photos. (NACA RM L51D25)

Some effects of fuselage interference, wing interference, and sweepback on the damping-in-roll characteristics of untapered wings with an aspect ratio of 3.7 and NACA 65A009 airfoil sections were obtained in the Mach number range between 0.6 and 1.7 by use of techniques which employed rocket-propelled test vehicles. It is shown that the damping in roll of configurations with either straight or sweptback wings was essentially unchanged by the presence of a fuselage having a fuselage-diameter—wing-span ratio of 0.191, that increasing the number of either straight or 45° sweptback semispan wings decreased the damping-in-roll coefficients at supersonic Mach numbers, and that changing the angle of sweepback from 0° to 45° decreased the damping in roll, particularly at supersonic speeds.

NACA RM L51D26

COMPARISON OF ZERO-LIFT DRAG DETERMINED BY FLIGHT TESTS AT TRANSONIC SPEEDS OF PYLON, UNDERSLUNG, AND SYMMETRICALLY MOUNTED NACELLES AT 40 PERCENT SEMISPAN OF A 45° SWEPTBACK WING AND BODY COMBINATION. Sherwood Hoffman. June 1951. 18p. diagrs., photos., tabs. (NACA RM L51D26)

The drag of a 45° sweptback wing and body configuration with nacelles has been obtained through transonic flight tests at zero lift. Nacelle positions were investigated at 40 percent of the semispan for the following arrangements: a nacelle mounted on a sweptforward (from wing) pylon, an underslung nacelle, and a symmetrically mounted nacelle.

NACA RM L51J08

EFFECT OF VERTICAL LOCATION OF A HORIZONTAL TAIL ON THE STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A 45° SWEPTBACK-WING - FUSELAGE COMBINATION OF ASPECT RATIO 8 AT A REYNOLDS NUMBER OF 4.0×10^6. Reino J. Salmi and William A. Jacques. January 1952. 42p. diagrs., photos. (NACA RM L51J08)

The results of a wind-tunnel investigation to determine the effects of a horizontal tail on the static longitudinal stability characteristics of a 45° sweptback-wing—fuselage combination of aspect ratio 8.0 are presented. The tests were made at a Reynolds number of 4.0×10^6 and a Mach number of 0.19 with various tail positions, with and without high-lift and stall-control devices, and at two wing incidence angles.

NACA RM L52D04a

TRANSONIC FLIGHT TESTS TO COMPARE THE ZERO-LIFT DRAGS OF UNDERSLUNG NACELLES VARIED SPANWISE ON A 45° SWEPTBACK WING AND BODY COMBINATION. Sherwood Hoffman. July 1952. 16p. diagrs., photos. (NACA RM L52D04a)

The effect on zero-lift drag at transonic speeds of varying the spanwise location of an underslung nacelle on a high-aspect-ratio, 45° sweptback wing and body combination has been determined by use of rocket-propelled models. Favorable interference effects were obtained for the underslung nacelles at the wing tips throughout the speed range.

NACA RM L52D18

WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS IN PITCH OF WING-FUSELAGE COMBINATIONS AT HIGH-SUBSONIC SPEEDS. SWEEP SERIES. James W. Wiggins and Richard E. Kuhn. July 1952. 41p. diagrs., photos. (NACA RM L52D18)

This paper presents the aerodynamic characteristics of wing-fuselage combinations of aspect ratio 4 and taper ratio of 0.6 with sweep angles ranging from 3.6° to 60° at the quarter-chord line. The tests covered a Mach number range from 0.4 to 0.95 at Reynolds number of 2,000,000 to 3,500,000 and an angle-of-attack range from -2° to 26°.

NACA RM L52D21a

AN ANALYSIS OF THE PRESSURE DISTRIBUTION MEASURED ON A BODY OF REVOLUTION AT TRANSONIC SPEEDS IN THE SLOTTED TEST SECTION OF THE LANGLEY 8-FOOT TRANSONIC TUNNEL. Bruce B. Estabrooks. June 1952. 42p. diagrs. (NACA RM L52D21a)

An analysis is presented of the pressure distributions measured in the Langley 8-foot transonic tunnel on a body of revolution of fineness ratio 10. Flow phenomena are discussed and the normal-force, pitching-moment, and pressure-drag data are presented at angles of attack from 0° to 20° for a range of Mach numbers from 0.89 to 1.13.

NACA RM L52D22a

DAMPING IN ROLL OF MODELS WITH 45°, 60°, AND 70° DELTA WINGS DETERMINED AT HIGH SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS WITH ROCKET-POWERED MODELS. E. Claude Sanders, Jr. June 1952. 18p. diagrs., photos. (NACA RM L52D22a)

Rocket-powered models have been flown to determine the damping in roll at zero lift of some delta wings which were swept 45°, 60°, and 70° at the leading edge and had NACA 65A006 and hexagonal airfoil sections. The effects of leading-edge sweep and number of wings on the damping in roll are presented. Total drag coefficient at zero lift is also shown.

NACA RM L52D24a

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS FROM A FLIGHT INVESTIGATION OF A CRUCIFORM CANARD MISSILE CONFIGURATION HAVING AN EXPOSED WING-CANARD AREA RATIO OF 16:1. Martin T. Moul and Andrew R. Wineman. June 1952. 32p. diagrs., photos. (NACA RM L52D24a)

A 60° delta-wing canard missile configuration having an exposed wing-canard area ratio of 16:1 was flight-tested at the Langley Pilotless Aircraft Research Station at Wallops Island, Va. Longitudinal stability and control derivatives and drag characteristics were obtained at transonic and supersonic velocities, and were compared with a similar canard configuration differing only in control area.

NACA RM L52D24b

RESULTS OF TWO EXPERIMENTS ON FLUTTER OF HIGH-ASPECT-RATIO SWEPT WINGS IN THE TRANSONIC SPEED RANGE. W. T. Lauten, Jr., and Burke R. O'Kelly. July 1952. 22p. diagrs., photos., tabs. (NACA RM L52D24b)

Flutter data in the transonic speed range for four high-aspect-ratio swept wings have been obtained by use of rocket-propelled vehicles. Two wings, swept 45°, fluttered at a Mach number of 0.89 and the other two wings, swept 60°, fluttered at a Mach number of 1.09. The experimental flutter speeds compared favorably with the flutter speeds calculated from a theory which includes effects of mode shape and sweep and is based on two-dimensional incompressible flow.

NACA RM L52J03

EFFECTS OF TWIST AND CAMBER, FENCES, AND HORIZONTAL-TAIL HEIGHT ON THE LOW-SPEED LONGITUDINAL STABILITY CHARACTERISTICS OF A WING-FUSELAGE COMBINATION WITH A 45° SWEPTBACK WING OF ASPECT RATIO 8 AT A REYNOLDS NUMBER OF 4.0 x 10^6. Gerald V. Foster. December 1952. 30p. diagrs., photo. (NACA RM L52J03)

A wind-tunnel investigation was made at a Reynolds number of 4.0 x 10^6 and Mach number of 0.19 to determine the effects of twist and camber, fences, and horizontal-tail height on the longitudinal stability of an airplane configuration having a 45° sweptback wing of aspect ratio 8. The results indicate that large improvements in longitudinal stability can be obtained through the combined effects of twist and camber, a suitable arrangement of fences, and a properly located horizontal tail.

NACA RM L53D08

LONGITUDINAL STABILITY AND WAKE-FLOW CHARACTERISTICS OF A TWISTED AND CAMBERED WING-FUSELAGE COMBINATION OF 45° SWEEPBACK AND ASPECT RATIO 8 WITH A HORIZONTAL TAIL AND STALL-CONTROL DEVICES AT A REYNOLDS NUMBER OF 4.0 x 10^6. Gerald V. Foster. June 1953. 51p. diagrs., photos., tab. (NACA RM L53D08)

A wind-tunnel investigation was made to determine the low-speed static longitudinal stability characteristics of a twisted and cambered wing having sweepback of 45° and an aspect ratio of 8 in combination with a fuselage and horizontal tail. The results include the effect of a horizontal tail located at various vertical positions on the stability of the airplane configuration with and without fences, leading-edge flaps, and extended split flaps. The results of airflow surveys in the region of the horizontal tail are also presented.

NACA RM L53D17

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF A SPOILER-SLOT-DEFLECTOR COMBINATION ON AN NACA 65A006 WING WITH QUARTER-CHORD LINE SWEPT BACK 32.6°. Raymond D. Vogler. May 1953. 24p. diagrs. (NACA RM L53D17)

Results are presented of a wind-tunnel investigation at high subsonic speeds and angles of attack up to 20° to determine the lateral control characteristics of a spoiler, a deflector, and a spoiler-slot-deflector combination. The wing-fuselage combination had a wing with quarter-chord line swept back 32.6° and an NACA 65A006 section.

NACA RM L53D29

ESTIMATION OF WATER LANDING LOADS ON HYDRO-SKI-EQUIPPED AIRCRAFT. Emanuel Schnitzer. July 1953. 14p. diagrs. (NACA RM L53D29)

A summary of available methods developed at NACA for estimation of water landing loads on hydro-ski-equipped aircraft is presented. Two approaches to the problem of calculating landing loads are covered along with a modification to take into account the effect of shock strut mounting of the skis. A procedure is given for estimating hydro-ski pressure distributions during water landings. Pertinent references covering this material in detail are included.

NACA RM L54D06

DRAG AND HEAT TRANSFER ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) IN FREE FLIGHT TO MACH NUMBER 2 WITH BOTH CONSTANT AND VARYING REYNOLDS NUMBER AND HEATING EFFECTS ON TURBULENT SKIN FRICTION. Joseph P. Maloney. June 1954. 34p. diagrs., photo. (NACA RM L54D06)

Skin-friction drag, base drag, total drag, and heat transfer have been measured on a parabolic body of revolution in free flight for Mach numbers from 1.35 to 2.01 and Reynolds numbers from 5.7×10^6 to 111.3×10^6. Average skin-friction-drag coefficients were determined when the heating effect on the skin friction was (a) constant and (b) varying. Heat-transfer coefficients determined from measured skin temperatures along the body were compared with the measured skin-friction coefficients by means of a modified Reynolds analogy.

NACA RM L54D13

EFFECT AT TRANSONIC SPEEDS OF INBOARD SPOILERS ON THE STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A 45° SWEPTBACK WING-BODY COMBINATION HAVING A LEADING-EDGE CHORD-EXTENSION. James H. Henderson. June 1954. 24p. diagrs., photo. (NACA RM L54D13)

This paper presents the effects at transonic speeds of inboard spoilers located along the 20- and 30-percent-wing-chord lines on the static longitudinal stability characteristics of a 45° sweptback wing-body combination having a leading-edge chord-extension. The effect of the chord-extension on longitudinal stability characteristics and of the spoilers on rolling-moment characteristics is also presented. The model was tested through a Mach number range from 0.86 to 0.99 and an angle-of-attack range from about -4° to about 14°. Reynolds number varied from about 1.25×10^6 to 1.60×10^6.

NACA RM L54D16a

LARGE-SCALE LOW-SPEED WIND-TUNNEL TESTS OF A MODEL HAVING A 60° DELTA HORIZONTAL CANARD CONTROL SURFACE AND WING TO OBTAIN STATIC-LONGITUDINAL-STABILITY AND CANARD-SURFACE HINGE-MOMENT DATA. Dale L. Burrows. June 1954. 21p. diagrs. (NACA RM L54D16a)

A wind-tunnel investigation was made of a model equipped with a 60° delta wing and a 60° delta horizontal canard surface to determine the static longitudinal stability, control, and canard-surface hinge-moment characteristics at low speeds and at a Reynolds number of 9×10^6. Two longitudinal canard-surface positions were tested. Data of lift, drag, pitching moments, and canard-surface hinge moments are presented through an angle-of-attack range of -10° to 45° and a canard-surface deflection range of -5° to 20°.

NACA - Langley Field, Va.

NACA RM L54D23

AN INVESTIGATION OF A METHOD FOR OBTAINING HYDRODYNAMIC DATA AT VERY HIGH SPEEDS WITH A FREE WATER JET. Bernard Weinflash and John R. McGehee. June 1954. 28p. diagrs., photos., tabs. (NACA RM L54D23)

Information is presented on the feasibility of using a rectangular free water jet to obtain hydrodynamic data at very high speeds. The 3-inch by 3/4-inch jet investigated was actuated by compressed air which forced the water through a nozzle at speeds from about 80 to 200 feet per second. Total-head pressure distributions in the jet up to 8 inches downstream of the nozzle exit are presented and experimental hydrodynamic lift data are given for two models planing on the 3-inch-wide surface of the jet. These planing data are compared with similar data obtained in the Langley towing tanks. The data obtained in this investigation indicate that it is feasible to use a free water jet as a hydrodynamic test facility for obtaining planing data at very high speeds.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1206

A REVISED GUST-LOAD FORMULA AND A RE-EVALUATION OF V-G DATA TAKEN ON CIVIL TRANSPORT AIRPLANES FROM 1933 TO 1950. Kermit G. Pratt and Walter G. Walker. 1954. ii, 9p. diagrs., tabs. (NACA Rept. 1206. Supersedes TN 2964; TN 3041)

A revised gust-load formula with a new gust factor is derived to replace the gust-load formula and alleviation factor widely used in gust studies. The revised formula utilizes the same principles and retains the same simple form of the original formula but provides a more appropriate and acceptable basis for gust-load calculations. The gust factor is calculated on the basis of a one-minus-cosine gust shape and is presented as a function of a mass-ratio parameter in contrast to the ramp gust shape and wing loading, respectively, used for the alleviation factor. A summary of gust-velocity data from V-G records taken on civil transport airplanes from 1933 to 1950, reevaluated by the revised formula, is also presented.

NACA Rept. 1213

MINIMUM-DRAG DUCTED AND POINTED BODIES OF REVOLUTION BASED ON LINEARIZED SUPERSONIC THEORY. Hermon M. Parker. 1955. ii, 9p. diagrs. (NACA Rept. 1213. Supersedes TN 3189)

The linearized-drag integral for bodies of revolution at supersonic speeds is presented in a double-integral form which is not based on slender-body approximations but which reduces to the usual slender-body expression in the proper limit. With the aid of a suitably chosen auxiliary condition, the minimum-external-wave-drag problem is solved for a transition section connecting two semi-infinite cylinders. The projectile tip is a special case and is compared with the Von Kármán projectile tip. Calculations are presented which indicate that the method of analysis gives good first-order results in the moderate supersonic range.

NACA Rept. 1227

AN INVESTIGATION OF THE MAXIMUM LIFT OF WINGS AT SUPERSONIC SPEEDS. James J. Gallagher and James N. Mueller. 1955. ii, 28p. diagrs., photos., tabs. (NACA Rept. 1227. Supersedes RM L7J10)

Results of an investigation are presented for a variety of wing plan forms of random thickness distributions tested at Mach numbers of 1.55, 1.90, and 2.32 and at angles of attack ranging from zero up through the angle at which maximum lift occurred. In general, at these Mach numbers the value of maximum lift coefficient was approximately 1.05 ± 0.05; it appeared to be independent of plan form and decreased slightly with increasing Mach number. No discontinuities in lift occurred from zero angle of attack through maximum lift, which was attained at an angle of attack of approximately 40°. Lift-drag ratios at maximum lift were of the order of 1.0.

NACA Rept. 1241

THEORETICAL AND ANALOG STUDIES OF THE EFFECTS OF NONLINEAR STABILITY DERIVATIVES ON THE LONGITUDINAL MOTIONS OF AN AIRCRAFT IN RESPONSE TO STEP CONTROL DEFLECTIONS AND TO THE INFLUENCE OF PROPORTIONAL AUTOMATIC CONTROL. Howard J. Curfman, Jr. 1955. ii, 21p. diagrs. (NACA Rept. 1241. Supersedes RM L50L11)

Through theoretical and analog results the effects of two nonlinear stability derivatives on the longitudinal motions of an aircraft have been investigated. Nonlinear functions of pitching-moment and lift coefficients with angle of attack were considered. Analog results of aircraft motions in response to step elevator deflections and to the action of the proportional control systems are presented. The occurrence of continuous hunting oscillations was predicted and demonstrated for the attitude stabilization system with proportional control for certain nonlinear pitching-moment variations and autopilot adjustments.

NACA RM 56B07

ELEVATED-TEMPERATURE FATIGUE PROPERTIES OF TWO TITANIUM ALLOYS. William K. Rey. April 1956. 28p. diagrs., photo., tabs. (NACA RM 56B07)

The unnotched fatigue properties of two titanium alloys were evaluated at temperatures from room

*AVAILABLE ON LOAN ONLY.

ADDRESS REQUESTS FOR DOCUMENTS TO NACA, 1512 H ST., NW., WASHINGTON 25, D. C., CITING CODE NUMBER ABOVE EACH TITLE, THE REPORT TITLE AND AUTHOR.

temperature to 1,000° F. The results are presented in tabular form and as curves of stress versus cycles to failure for each test temperature. The decrease in endurance strength with an increase in temperature is shown by a curve of endurance strength versus temperature for each alloy.

NACA RM A56B10

REDUCTION OF WAVE DRAG OF WING-BODY COMBINATIONS AT SUPERSONIC SPEEDS THROUGH BODY DISTORTIONS. William C. Pitts. April 1956. 9p. diagrs. (NACA RM A56B10)

Several methods for the reduction of the wave drag of wing-body combinations by axisymmetric and nonaxisymmetric body distortions are discussed. Experimental results for several wing plan forms show sizable reductions in drag for aspect ratios of current interest. A significant part of the drag reduction is due to the nonaxisymmetric distortion.

NACA RM E56A27

THEORETICAL PERFORMANCE OF JP-4 FUEL AND LIQUID OXYGEN AS A ROCKET PROPELLANT. I - FROZEN COMPOSITION. Vearl N. Huff and Anthony Fortini. April 1956. 35p. diagrs., tabs. (NACA RM E56A27)

Theoretical rocket performance parameters were calculated for JP-4 fuel with liquid oxygen. Frozen composition was assumed during the isentropic expansion process. Data were calculated for equivalence ratios of 1 to 3, chamber pressures of 300 and 600 pounds per square inch, and pressure ratios of 1 to 1500. A correlation is given which permits the determination of performance for a wide range of chamber pressures. The maximum values of specific impulse for chamber pressures of 300 and 600 pounds per square inch absolute and an exit pressure of 1 atmosphere were 271.8 and 250.4, respectively, at 32 weight percent fuel.

NACA TM 1403

ON THE INSTABILITY OF METHODS FOR THE INTEGRATION OR ORDINARY DIFFERENTIAL EQUATIONS. (Über die Instabilität von Methoden zur Integration gewöhnlicher Differentialgleichungen). Heinz Rutishauser. April 1956. 15p. (NACA TM 1403. Trans. from Zeitschrift für angewandte Mathematik und Physik, v.3, 1952, p.65-74)

In the numerical solution of a differential equation as a difference equation, the latter is usually of higher order and therefore has more solutions than the original differential equation. It may well be that some of these "extra" solutions grow faster than any solution of the given equation; in this case the computational solution has the tendency to follow one of these and has after a certain number of integration steps nothing to do with the original differential equation. The author gives some examples and a criterion for stability of integration methods. This criterion is then applied to some well-known integration formulas.

NACA TN 3579

VAPOR-PHASE OXIDATION AND SPONTANEOUS IGNITION - CORRELATION AND EFFECT OF VARIABLES. Donald E. Swarts and Milton Orchin, University of Cincinnati. April 1956. 32p. diagrs., tabs. (NACA TN 3579)

The spontaneous ignition temperatures of eight structurally different hydrocarbons were determined and correlated with the behavior of the same hydrocarbons toward vapor-phase oxidation. Since good correlation of the two phenomena was obtained, it is likely that similar oxidative mechanisms are operative in both.

NACA TN 3628

AN ANALYSIS OF ESTIMATED AND EXPERIMENTAL TRANSONIC DOWNWASH CHARACTERISTICS AS AFFECTED BY PLAN FORM AND THICKNESS FOR WING AND WING-FUSELAGE CONFIGURATIONS. Joseph Weil, George S. Campbell and Margaret S. Diederich. April 1956. 92p. diagrs., photos., tabs. (NACA TN 3628. Supersedes RM L52I22)

This paper presents a summary of the effects of changes in wing plan form and thickness ratio on the downwash characteristics of wing and wing-fuselage configurations in the Mach number range between 0.6 and 1.1. Data obtained by the transonic-bump technique at two tail heights have been compared with theoretical estimations made in the subsonic and supersonic Mach number range.

NACA TN 3634

CALCULATIONS OF THE RATE OF THERMAL DISSOCIATION OF AIR BEHIND NORMAL SHOCK WAVES AT MACH NUMBERS OF 10, 12, AND 14. George P. Wood. April 1956. 40p. diagrs., tabs. (NACA TN 3634)

Calculations of the rate of dissociation of air have been based on available theory and available experimental results with other gases. The results show that the distance behind a normal shock wave required for a moderately large fraction of the oxygen to dissociate varies widely with Mach number and density, from approximately hundreds of meters to a fraction of a millimeter. The distance required for a significant portion of the nitrogen to dissociate (outside the boundary layer) is shown to be greater than the length of a vehicle at any density and at any Mach number less than 14.

NACA TN 3636

THE ACCURACY OF THE SUBSTITUTE-STRINGER APPROACH FOR DETERMINING THE BENDING FREQUENCIES OF MULTISTRINGER BOX BEAMS. William W. Davenport. April 1956. 28p. diagrs., tab. (NACA TN 3636)

The accuracy of the substitute-stringer approach for including the effects of shear lag in the calculation of the transverse modes and frequencies of multistringer box beams is investigated. Box beams, the

covers of which consist of normal-stress-carrying stringers on sheets which carry not only shear but also normal stress, are analyzed exactly. Frequencies of beams with various numbers of stringers, obtained by means of this exact analysis, serve to determine the possible accuracy of the frequencies obtained by the substitute-stringer approach.

NACA TN 3637

FLIGHT INVESTIGATION OF THE EFFECTIVENESS OF AN AUTOMATIC AILERON TRIM CONTROL DEVICE FOR PERSONAL AIRPLANES. William H. Phillips, Helmut A. Kuehnel and James B. Whitten. April 1956. 42p. diagrs., photos., tab. (NACA TN 3637)

An analytical and flight investigation has been made to determine the effectiveness of an automatic aileron trim control device in conjunction with preloaded aileron centering springs in improving spiral stability characteristics of a personal airplane. The results indicate that the device can maintain the airplane in level flight under instrument conditions despite disturbances due to moderate turbulence or trim changes with airspeed and flight condition.

NACA TN 3638

ON PANEL FLUTTER AND DIVERGENCE OF INFINITELY LONG UNSTIFFENED AND RING-STIFFENED THIN-WALLED CIRCULAR CYLINDERS. Robert W. Leonard and John M. Hedgepeth. April 1956. 52p. diagrs. (NACA TN 3638)

A preliminary theoretical investigation of the panel flutter and divergence of infinitely long, unstiffened and ring-stiffened thin-walled circular cylinders is described. Analytical criteria for the location of stability boundaries are presented along with a limited number of computed results.

NACA TN 3642

EFFECT OF SHALLOW WATER ON THE HYDRODYNAMIC CHARACTERISTICS OF A FLAT-BOTTOM PLANING SURFACE. Kenneth W. Christopher. April 1956. 36p. diagrs., photos., tab. (NACA TN 3642)

The effects on the planing characteristics of the clearance between a flat-bottom planing surface and the tank bottom are presented. The range of trims investigated was from 4° to 20° for wetted-length—beam ratios of 0.4 to 6.4. Each condition was investigated over a range of clearances of from 0.2 to 1.6 beams. All the measured values increased with decreasing clearance. A description of the monorail and its associated apparatus is included.

NACA TN 3646

A THEORY FOR THE ELASTIC DEFLECTIONS OF PLATES INTEGRALLY STIFFENED ON ONE SIDE. Robert F. Crawford. April 1956. 21p. diagrs. (NACA TN 3646)

An elastic-deflection theory is presented for anisotropic plates which exhibit coupling between bending and stretching. In particular, the theory provides a basis for analyzing plates integrally stiffened on one side. The effect of coupling is responsible for the presence of added terms in the potential-energy expression, the small- and large-deflection equations of equilibrium, and the boundary conditions which do not occur in ordinary plate theory. Example calculations show that, in the case of a simply supported square plate loaded in compression and having equal flexural stiffnesses in the principal directions, coupling may significantly lower the in-plane compressive load at which deflections grow rapidly.

NACA TN 3650

RESULTS OF A FLIGHT INVESTIGATION TO DETERMINE THE ZERO-LIFT DRAG CHARACTERISTICS OF A 60° DELTA WING WITH NACA 65-006 AIRFOIL SECTION AND VARIOUS DOUBLE-WEDGE SECTIONS AT MACH NUMBERS FROM 0.7 TO 1.6. Clement J. Welsh. April 1956. 13p. diagrs., photo. (NACA TN 3650. Supersedes RM L50F01)

Results of an exploratory free-flight investigation at zero lift of several rocket-powered drag-research models equipped with 60° sweptback delta wings are presented for a Mach number range from about 0.70 to 1.60. The airfoil sections tested included the NACA 65-006 and a series of double-wedge sections with various positions of maximum thickness.

NACA TN 3655
National Advisory Committee for Aeronautics.
METHOD OF CALCULATING CORE DIMENSIONS OF CROSSFLOW HEAT EXCHANGER WITH PRESCRIBED GAS FLOWS AND INLET AND EXIT STATES. E. R. G. Eckert and Anthony J. Diaguila. April 1956. 25p. diagrs. (NACA TN 3655)

A calculation procedure is presented for determining the dimensions of a heat-exchanger core with a prescribed heat-transfer surface. The procedure is applicable when the gas-flow quantities as well as the inlet and outlet gas conditions on both sides of the heat exchanger are specified. The procedure is applied to a numerical example.

NACA TN 3669

PERFORATED SHEETS AS A POROUS MATERIAL FOR DISTRIBUTED SUCTION AND INJECTION. Robert E. Dannenberg, Bruno J. Gambucci, and James A. Weiberg. April 1956. 27p. diagrs., photos. (NACA TN 3669)

Measurements were made of the resistance to air flow through a series of perforated metal sheets with open areas ranging from less than 1 percent up to 41 percent. The use of punch-perforated sheets as a

porous material for boundary-layer-control applications by means of distributed suction is discussed.

NACA TN 3670

DETERMINATION OF VORTEX PATHS BY SERIES EXPANSION TECHNIQUE WITH APPLICATION TO CRUCIFORM WINGS. Alberta Y. Alksne. April 1956. 40p. diagrs., photos. (NACA TN 3670)

A series method is applied to the computation of vortex positions behind a slender equal-span cruciform wing at any angle of bank as a function of the distance behind the trailing edge. Calculated paths are compared with the results of water-tank experiments and of a closed expression given in NACA TN 2605. The forces on an equal-span interdigitated cruciform tail behind a slender equal-span cruciform wing are calculated for four angles of bank from the vortex positions found by use of the series.

NACA TN 3672

INVESTIGATION AT HIGH SUBSONIC SPEEDS OF A BODY-CONTOURING METHOD FOR ALLEVIATING THE ADVERSE INTERFERENCE AT THE ROOT OF A SWEPTBACK WING. John B. McDevitt and William M. Haire. April 1956. 38p. diagrs., photos. (NACA TN 3672. Supersedes RM A54A22)

An experimental investigation was made of a body-contouring method for alleviating at subsonic speeds the adverse interference at the root of a 35° sweptback wing in combination with various bodies. Modifying the body shape did not significantly affect the aerodynamic characteristics at subcritical speeds. At Mach numbers above the critical, improved aerodynamic characteristics were evidenced by large reductions of drag, an increase in lift-curve slope, and a reduced change of pitching-moment-curve slope with increasing Mach number.

NACA TN 3674

THEORETICAL PRESSURE DISTRIBUTIONS FOR SOME SLENDER WING-BODY COMBINATIONS AT ZERO LIFT. Paul F. Byrd. April 1956. 39p. diagrs. (NACA TN 3674. Supersedes RM A54J07)

Theoretical calculations are made of the pressure distributions for some slender, symmetrical wing-body combinations in subsonic and supersonic flow. The combinations consist first of nonlifting, sweptback wings mounted on a circular cylinder and second of such wings mounted on a body indented so that the local cross-sectional area of the combination is constant. The results indicate that indentation straightens out the isobars along the wing and diminishes the maximum perturbation velocities.

NACA TN 3678

INFLUENCE OF ALLOYING UPON GRAIN-BOUNDARY CREEP. F. N. Rhines, W. E. Bond and M. A. Kissel, Carnegie Institute of Technology. April 1956. 16p. diagrs., tab. (NACA TN 3678)

Grain-boundary displacement, occurring in bicrystals during creep at elevated temperature (350° C), was measured as a function of the copper content (0.1 to 3 percent) in a series of aluminum-rich aluminum-copper solid-solution alloys. Because alloying effects alone were to be investigated, the conditions of observation were limited to a single temperature and range of stress.

NACA TN 3689

INVESTIGATION BY THE TRANSONIC-BUMP METHOD OF A 35° SWEPTBACK SEMISPAN MODEL EQUIPPED WITH A FLAP OPERATED BY A SERIES OF SERVOVANES LOCATED AHEAD OF AND GEARED TO THE FLAP. William H. Phillips and Robert F. Thompson. April 1956. 39p. diagrs., photo. (NACA TN 3689. Supersedes RM L51J10)

Lift, drag, pitching-moment, rolling-moment, and yawing-moment data in the Mach number range from 0.6 to 1.0 obtained from wind-tunnel tests of a low-aspect-ratio sweptback airfoil model with a servovane control are presented. The control utilizes the drag force and spoiler action of a set of vanes to deflect a flap-type control. Comparison of lift increment and center-of-pressure location is made with previously published data from tests of a conventional flap-type control.

NACA TN 3690

NORMAL COMPONENT OF INDUCED VELOCITY IN THE VICINITY OF A LIFTING ROTOR WITH A NONUNIFORM DISK LOADING. Harry H. Heyson and S. Katzoff. April 1956. i, 45p. diagrs. (NACA TN 3690)

Part I presents a method for computing, from available calculations for uniform disk loading, the effect of nonuniform circularly symmetrical disk loading on the normal component of induced velocity in the vicinity of a lifting rotor. Charts of the normal component of induced velocity are given for the longitudinal plane of symmetry and for the major axes of rotors with two different, nonuniform, circularly symmetrical disk-load distributions. Part II develops certain symmetry relations for the induced velocities in the plane of a uniformly loaded rotor and also develops relations between the radial load distribution of the rotor and the radial variation of induced velocities in the wake.

NACA TN 3691

ANALYSIS AND COMPARISON WITH THEORY OF FLOW-FIELD MEASUREMENTS NEAR A LIFTING ROTOR IN THE LANGLEY FULL-SCALE TUNNEL. Harry H. Heyson. April 1956. 162p. diagrs., photos., tab. (NACA TN 3691)

Measurements of stream angles and velocities were made in several planes both near and behind a single rotor in four different flight conditions in the Langley full-scale tunnel. These measurements indicate that available theory may be used to calculate with reasonable accuracy the induced flow over the forward three-quarters of the disk for these flight conditions if the rotor disk-load distribution is accounted for. Rearward of this point, calculations of the induced velocity are increasingly inaccurate due to the rolling up of the trailing-vortex system. Farther rearward, well behind the rotor, the flow may be represented more accurately by the flow behind a uniformly loaded wing.

NACA TN 3711

SOME EFFECTS OF GUIDE-VANE TURNING AND STATORS ON THE ROTATING STALL CHARACTERISTICS OF A HIGH HUB-TIP RATIO SINGLE-STAGE COMPRESSOR. Eleanor L. Costilow and Merle C. Huppert. April 1956. 52p. diagrs., tab. (NACA TN 3711)

The rotating stall characteristics of several guide-vane - rotor and guide-vane - rotor - stator configurations were investigated. Guide vanes having turning angles of -22.5°, 0°, 22.5°, and 40° were used. The stage hub-tip ratio was 0.9. Results indicate that the initial rotating stall point, number of stall zones formed, and stall propagation rate of a configuration depend not only upon blade-row inlet angle and pressure-rise characteristic, but also upon the overall characteristics of the multiblade row unit as well. The number of stall zones formed in the annulus did not appear to depend upon guide-vane turning or the presence of stators.

BRITISH REPORTS

National Gas Turbine Establishment (Gt. Brit.)
THE DEVELOPMENT OF A FLOW VISUALIZATION TECHNIQUE. E. C. Roberson. November 1955. 39p. diagrs., photos. (NGTE R. 181)

A number of flow visualization techniques were examined and from them the water analogy was chosen for its ability to give more complete, rapid and accurate information on the nature of flow regimes. In the variant of the technique developed, synthetic resin spheres having suitable optical properties were used as markers. Precautions were taken to make the particle/fluid density ratio fall within limits indicated by mathematical analysis. This was checked experimentally. A rig was designed to meet flow requirements of a wide range of combustion system models and in it rubber linings were used to obviate turbidity produced by fluid corrosion on metal parts. Lighting systems were devised to provide adequate illumination for photography and a technique was developed for measuring quickly and accurately the flow angles and velocities recorded in photographs.

Royal Aircraft Establishment (Gt. Brit.)
VISUAL AIDS AND THEIR EFFECT ON LANDING SUCCESS AND SAFETY. E. S. Calvert. (Lecture delivered to Wissenschaftliche Gesellschaft fur Luftfahrt, Augsberg, October 1955). October 1955. 17p. diagrs. (RAE EL. 1486)

It is shown that the installation of the Crossbar System of approach lighting at London Airport enables the operating limits there to be lowered to about one-third. It also reduced the failure rate in first attempts to land by about 15 times in meteorological visibilities of the order of half a mile. One main problem, which is largely one of safety, still remains. This is to devise some simple means of improving visual guidance during the flare-out, that is, from a height of about 100 feet downwards. This is necessary on noninstrument runways as well as on instrument runways in order to reduce the number of undershoots and enable improved approach couplers to be used to lower heights.

Royal Aircraft Establishment (Gt. Brit.)
THE VELOCITY OF PROPAGATION OF STRAIN IN TEXTILE CABLES. B. J. Brinkworth. November 1955. 15p. diagrs., tab. (RAE Tech. Note Mech. Eng. 211)

Existing data are examined, and it is concluded that the conditions under which cables are used in practice and the complex constructions employed are so different from those of the laboratory tests previously made that no reliable interpretation is possible. An experimental method devised to obtain values in actual cables is described, and typical values for flax and nylon are given. The value of strain velocity is found to increase with impact velocity and thus the effective modulus of elasticity with dynamic strain. Extensions to the present investigation are proposed, covering a wider range of materials and construction and the effect of initial static loading.

Royal Aircraft Establishment (Gt. Brit.)
THE EFFECT OF STRESS WAVES ON THE STRENGTH OF BRAKE PARACHUTE CABLES. B. J. Brinkworth. July 1955. 31p. diagrs., tabs. (RAE Tech. Note Mech. Eng. 202)

Equations of transient tension are derived for both ends of a cable under longitudinal impact by a finite mass, and the results are presented in a form readily applicable to brake parachute systems. A comparison is made with the strain-energy solution in common use. The particular case of an air-launched body is examined with certain basic assumptions, and the solutions are again presented in

graphical form. Consideration is given to possible effects of attenuation in braided cables and the influence of material properties on the velocity of stress propagation and the maximum elastic stress under impact.

Royal Aircraft Establishment (Gt. Brit.)
RESULTS OF A FLIGHT INVESTIGATION ON CLEAR AIR TURBULENCE AT LOW ALTITUDE USING A METEOR MK.7 AIRCRAFT. R. M. Allan. September 1955. 16p. diagrs., photo., tabs. (RAE Tech. Note Aero 2390)

Low level runs were made over a given route at heights below 1000 feet above ground and at an airspeed of 400 knots. A distance of 6080 nautical miles was covered and the accelerations due to gusts were recorded by a continuous trace accelerometer. The results of all the runs showed that, on the average, a 1g gust or greater occurred every 7.06 minutes. Comparison with other information on this subject showed that the results from this investigation fitted in with existing data. There were considerably more positive than negative gusts, the factor being 18 at 1.2g or greater. It would appear that for the area in which the flights were made, turbulence near the ground is not isotropic. A consideration of meteorological factors showed that on this route wind is far more powerful in producing turbulence at low altitude than the effect of sun.

LUBRICATION BY FILMS OF SOLID MATERIALS. E. B. Bielak, E. Kay and E. W. J. Mardles. December 1955. 17p. diagrs., photos., tab. (RAE Tech. Note Chem. 1271)

Lubricants such as graphite, molybdenum disulphide, lithium stearate are investigated between various metal bearing surfaces, before and after treatment. Results of measurement of coefficients of friction under different conditions are given in tables and figures. Although benefit is obtainable with solid lubricants, especially under extreme temperature conditions, their lubricating properties are sensitive to rate of movement, thickness of film, atmospheric conditions, presence of oil, etc., so that considerable effort is required to determine the optimum conditions of application for any bearing or instrument. Some improvement in the lubricating properties of solid powders is obtained by surface treating the powder with a lyophobic film.

A PRELIMINARY STUDY OF THE EFFECTS OF KINETIC HEATING ON THE DESIGN AND TESTING OF AIRCRAFT STRUCTURES. W. H. Horton. October 1955. 48p. diagrs., photos., tab. (RAE Tech. Note Structures 177)

This paper discusses the changes in methods of stress analysis which may be expected to occur with the introduction of kinetic heating, including new problems in creep and thermal fatigue. New techniques of structural testing are discussed. Automatic ground simulation of kinetic heating is described. This is a reproduction of a paper read at the Centennial Celebrations of the Polytechnic Institute of Brooklyn under the title "The Influence of Kinetic Heating on the Design and Testing of Aircraft Structures," and published in the Proceedings of the Conference in 1955. Issued as an RAE Technical Note with the concurrence of Polytechnic Institute of Brooklyn, USA.

Royal Aircraft Establishment (Gt. Brit.)
FLAME SPEEDS IN HYDRAZINE VAPOUR AT LOW PRESSURES. A. R. Hall. September 1955. 15p. diagr., photo. (RAE Tech.Note RPD 129)

The burning velocity of the self-decomposition flame of 97-percent hydrazine (N_2H_4) vapor at 120° C has been determined by a burner method at pressures of 3, 7, and 15 cm of mercury. The velocity remains relatively constant over this range at around 185 cm sec^{-1} and is thus little different from the value previously found at atmospheric pressure. It is concluded that the rate-determining process is close to a second-order reaction and that the combustion proceeds by a chain mechanism. Some visual and spectrographic observations have been made on flames of hydrazine, hydrazine/oxygen, hydrazine/nitric oxide and ammonia/nitric oxide at low pressure. These suggest that the combustion of hydrazine and oxygen takes place in what may be regarded as two stages.

Royal Aircraft Establishment (Gt. Brit.)
THE THEORY OF THE AIRCRAFT HEIGHT AND AIRSPEED COMPUTER. D. Martin. September 1955. 17p. (RAE Tech. Memo. IAP 624)

Expressions are derived relating true height to indicated height as given by a barometric altimeter calibrated to the I. C. A. N. law and relating true airspeed to indicated airspeed, true outside air temperature, and indicated height. Approximations to these expressions employed in height and airspeed computers in use up to 1945 are discussed. Possible sources of error of the computers, due both to the approximations made and to variations from I. C. A. N. conditions, are considered and evaluations made of the order of the errors. Developments of this type of computer in the immediate years following 1945 are outlined.

AN AUTOMATIC SELF-BALANCEING CAPSULE MANOMETER. G. F. Midwood and R. W. Hayward. July 1955. 22p. diagrs., photos. (RAE Tech. Note Aero 2382)

This note contains a brief description of an automatic self-balancing capsule manometer which has been developed primarily for the measurement of pressures encountered in the operation of supersonic wind tunnels. A remote indicating system is em-

ployed which is suitable for use with digital recording and card punching apparatus. The instrument has been designed to cover a range of 0-2 atmospheres absolute and has been adjusted and calibrated to give an accuracy of 0.01 in. Hg over the range 0.5 in. Hg to 60 in. Hg absolute.

Royal Aircraft Establishment (Gt. Brit.)
IMPURITIES IN TITANIUM: PHOSPHORUS. D. A. Sutcliffe. September 1955. 11p. diagrs., photos., tabs. (RAE Tech. Note Met. 227)

Binary titanium phosphorus alloys containing up to 3.8 percent phosphorus have been prepared by arc melting. All the alloys have been hardness tested; tensile and impact tests have been made at room temperature on the alloys containing up to 1.13 percent phosphorus. The results show that the addition of 0.25 phosphorus causes a marked rise in hardness and tensile strength with a corresponding loss in percentage elongation and impact strength. Further additions of phosphorus up to 1.13 percent caused a continuation of these trends though not so rapidly as at first. Titanium phosphorus alloys in the "as cast" condition exhibited a eutectic structure.

N-42462*

Royal Aircraft Establishment (Gt. Brit.)
A THREE-PHASE VIBRATOR CONVERTOR. R. H. Evans. September 1955. 16p. diagrs. (RAE Tech. Note EL 106)

This note describes a proposed method of power conversion from direct current to a three-phase alternating-current supply of constant frequency by means of vibrator converters with their driving systems electrically interconnected. The alternating current may be used directly or it may be rectified, in which case it is expected that, compared with the single-phase vibrator converter, the power rating and life will be increased and the amount of smoothing required considerably reduced.

Royal Aircraft Establishment (Gt. Brit.)
FATIGUE TESTS ON SPECIMENS FROM ALUMINIUM ALLOY B.S. L.40 METEOR TAIL PLANE SPAR BOOM EXTRUSION. M. S. Binning and J. T. Ballett. September 1955. 11p. diagrs., tabs. (RAE Tech. Note Met. 229)

Fatigue tests have been made on specimens from extruded angle section in aluminum alloy B.S. L40 to provide information on the effect on fatigue strength of mean stress, surface conditions and a stress raiser in the form of a rivet hole. The tests, made in Haigh fatigue machines, indicated that polishing the extruded surface of plain specimens gave an increase of approximately 15 percent in the fatigue strength. With "as extruded" material the ratio of fatigue strength of plain specimens to that of specimens incorporating the stress raiser (1/8-in. diameter hole) was about 1.7, and polishing such specimens made little, if any, improvement.

N-42464*

Royal Aircraft Establishment (Gt. Brit.)
AN EXTENSION OF THE THEORY OF THERMAL EXPLOSION AND ITS APPLICATION TO THE OSCILLATORY BURNING OF EXPLOSIVES. D. M. Clemmow and J. D. Huffington. September 1955. 28p. diagrs., tabs. (RAE Tech. Note RPD 128)

The critical conditions for the explosion of a slab of explosive, subject to self-heating and with one face maintained at a fixed temperature and the other heated at a constant rate, are obtained by modification and extension of existing theory on thermal explosion. Critical thicknesses and surface temperatures at the initiation of explosion are calculated for cordite and methyl nitrate, and it is shown that the critical thicknesses decrease with increasing rate of surface heat transfer, being of the order of 1 micron or less for a surface temperature gradient of 10^7 °C/cm. The results are used to help interpret observations of the oscillatory burning of cordite which are consistent with the view that combustion is partly due to the successive explosion of discrete layers of thickness decreasing with increasing pressure, and therefore with surface heat transfer rate.

Royal Aircraft Establishment (Gt. Brit.)
A.C. CONTROLLED TRANSDUCTORS.
A. G. Milnes and T. S. Law. September 1955. 38p. diagrs. (RAE Tech. Note EL 93)

An analysis of the behavior of the single, auto-self-excited, transductor element is made for the condition when the control circuit has finite resistance. Consideration is given to control by direct voltage signal as an introduction to the performance with an alternating voltage signal of the same frequency as the supply. Factors influencing the output characteristic are examined and methods of improvement, such as phase shift and special bias arrangements, are discussed. Reference is made to the A.C. control of full-wave transductors and some push-pull circuits with half-wave and full-wave outputs. The behavior of a typical push-pull four-element design is examined experimentally and its performance when the control is by alternating-voltage signal is compared with that for direct-voltage control.

Royal Aircraft Establishment (Gt. Brit.)
ON THE USE OF A TENSOR TRANSFORMATION TO DESCRIBE THE ROTATION OF A RIGID BODY; WITH APPLICATIONS TO A WING OF VARIABLE SWEEP AND A RETRACTABLE UNDERCARRIAGE. Edward Hugh Bateman. October 1955. 20p. diagrs. (RAE Structures 190)

A general solution, which depends on a tensor transformation derived in a previous note (RAE TN Structures 121), is presented for defining the position of a rigid body after rotation on a known axis, and conversely for finding the direction of the axis when a body is transposed from one position to another, in a single rotation. Expressions are derived for the angles of sweep, incidence and dihedral, when a wing of variable sweep is rotated about any axis fixed in the aircraft. A method is given in detail for finding

the axis of rotation of an undercarriage when the extended and retracted orientations are defined in plan and elevation on an engineering drawing.

THE CHEMISTRY AND TECHNOLOGY OF FLEXIBLE POLYURETHANE (FLEXALKYD) FOAMS. L. N. Phillips. December 1955. 24p. diagr., photos., tabs. (RAE Chem. 503)

The type of alkyd required for producing flexible polyurethane foams has been investigated in some detail. The composition and the esterification conditions for a suitable resin (Flexalkyd) are given. Bubble modifiers, accelerators and a proportion of water are necessary for the production of uniform light-weight products. The heat resistance, chemical resistance and stress/strain behavior in compression of such foams have been examined. Important applications for polyurethane foams are as industrial sponges, upholstery, and as packaging materials. A technique has been developed for moulding packaging units by the foamed-in-place method.

Royal Aircraft Establishment (Gt. Brit.)
THE INFLUENCE OF PLAIN BEARINGS ON SHAFT WHIRLING. E. Downham. October 1955. 45p. diagrs., photos., tabs. (RAE Structures 192)

Experiments are described which show the effects of bearing length, bearing clearance, and lubricant viscosity on the critical whirling speeds of a single shaft rotor system supported in plain bearings. The critical speed of a two-bearing shaft-rotor system is shown to depend upon rotor unbalance for bearings of normal clearance. When the clearance is small relative to the bearing length, unsymmetric stiffness characteristics are obtained and produce two critical speeds instead of one. The lubricant in a drip-feed bearing is shown to have a stiffening effect, with consequent increase of critical whirling speed. It is also shown that the critical whirl amplitudes with dry bearings can be appreciably larger than those obtained with lubricated bearings.

SOME FATIGUE CHARACTERISTICS OF A TWO SPAR LIGHT ALLOY STRUCTURE (METEOR 4 TAILPLANE). K. D. Raithby and Jennifer Longson. January 1956. 31p. diagrs., photos., tabs. (RAE Structures 195)

Results are given for fatigue tests on 61 Meteor tailplanes, treated as representative small-scale wing systems and tested under a variety of loading conditions. The object of the investigation was to study the fatigue characteristics of a typical aircraft structure, in particular the effects of mean load and alternating load on the endurance. The effects of preloading, periodic overloading, and low temperatures were also investigated. Endurance curves are given for different mean loads; the results indicate that, for a given alternating load, the endurance is roughly inversely proportional to mean load. Substantial improvements in endurance may be obtained by preloading and by periodic overloading. The endurance at low temperatures is higher than at room temperature.

Marine Aircraft Experimental Establishment (Gt. Brit.) INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS. HYDRODYNAMIC STABILITY PART 14. THE EFFECT OF A TAILORED AFTERBODY ON STABILITY AND SPRAY CHARACTERISTICS WITH TEST DATA ON MODEL J. D. M. Ridland. October 1955. 40p. diagrs., photos., tabs. (MAEE F/Res/249)

The effects of a tailored afterbody on longitudinal stability, spray, directional stability, and elevator effectiveness are deduced from the results of tests on two models of length/beam ratio 11, which were alike in every respect except that of afterbody shape; one afterbody was of standard form and the other was tailored. It was found that tailoring the afterbody considerably improved stability characteristics, both longitudinal and directional, improved spray characteristics and slightly impaired elevator effectiveness. The detailed test results for the tailored afterbody model are also included and discussed.

SPRING TAB FLUTTER. PART I. A THEORETICAL INVESTIGATION ON WING-AILERON-TAB FLUTTER. R. A. Frazer and W. P. Jones. PART II. EXPERIMENTS ON BINARY AILERON-TAB FLUTTER. C. Scruton, J. Williams, and C. J. W. Miles. 1955. 95p. diagrs., tabs. (ARC R & M 2952. Supersedes ARC 5668; ARC 0.251; ARC 6290; ARC 0.251a; ARC 5917; ARC 0.275)

A theoretical discussion is given of wing-aileron-tab flutter, with special reference to influence of spring tab control. Numerical applications of the theory are made to two representative types of spring tab, and with the aid of special stability diagrams certain conclusions are drawn regarding conditions for flutter prevention. In relation to binary aileron-tab flutter it is shown that certain restrictions on aileron-tab density ratio should be observed, and that when a balancing mass for the tab is fitted its arms should be limited to a certain length. Calculations relating to ternary flutter indicate that the possibility of ternary flutter occurring when all the possible binary types are absent is very remote.

PRESSURE DISTRIBUTIONS: AXIALLY SYMMETRIC BODIES IN OBLIQUE FLOW. I. J. Campbell and R. G. Lewis. 1955. 23p. diagrs., tab. (ARC CP 213)

A simple picture, known from the work of I. Lotz, of the flow over the forward part of a body of revolution in oblique flow is derived from entirely elementary considerations. Pressure at any point of the (forward part of the) body at any angle of attack depends on three parameters whose values vary along the body. Variation of these parameters along the body can be determined from a relatively small number of wind tunnel or water tunnel measurements. Necessary water tunnel measurements have been made for four axially symmetric head shapes. Additional measurements have been made to illustrate the theoretical conclusions. Data for each head shape are adequate for a determination of the pressure coefficient at any point on the head shapes at any angle of attack (up to 6°, say). In particular, they can be used to determine the peak suction at any angle of attack and so the conditions for the onset of cavitation on the head.

ON THE LAMINAR BOUNDARY LAYER SEPARATION FROM THE LEADING EDGE OF A THIN AEROFOIL. P. R. Owen and L. Klanfer. 1955. 19p. diagrs., tabs. (ARC CP 220)

It is suggested that the length of bubble depends primarily on the Reynolds number based on the displacement thickness at the separation point; if the RN exceeds 400-500, the bubble is short: if less than this band of values, the bubble may be long. The RN in turn depends on the distance of the velocity peak on the upper surface of the airfoil from the front stagnation point and it is inferred that, at a given RN based on chord, a long bubble is more likely to form when the velocity peak is close to the stagnation point: but a scale effect, such as to cause the bubble to change from long to short as the RN is increased beyond a critical value, can also be expected. These observations are used to comment on certain peculiarities in the stalling behavior of thin sweptback wings.

THE GEARED ELEVATOR TAB AND TAIL-UNIT STIFFNESS REQUIREMENTS. Ll. T. Niblett. 1955. 18p. diagrs., tabs. (ARC R & M 2848; ARC 14,125. Supersedes RAE Structures 106)

The effect of a flexible, geared, elevator tab upon the validity of the stiffness criteria for tail units and rear fuselages is examined. To this end, the distortions of a hypothetical, semirigid tail unit under the air loads induced when the elevator is displaced are calculated for various arrangements of tab and forward aerodynamic balance of the elevator. Notice is also taken of the loss of control effectiveness and change in elevator hinge moment resulting from these distortions. A torsional-stiffness criterion for tabs is proposed.

MODEL TESTS ON THE ASYMMETRY OF AIRFLOW OCCURRING IN TWIN-INTAKE SYSTEMS AT SUBSONIC SPEEDS. J. Seddon and W. J. G. Trebble. 1955. 15p. diagrs., tabs. (ARC R & M 2910; ARC 13,932. Supersedes RAE Aero 2411)

The tests have shown that asymmetry of flow occurs in typical twin-intake systems under conditions which may be encountered in a dive, or at lower speeds on reducing the engine air flow. Intake loss theory provides a simple formula for estimating the critical flow value of a given arrangement. The chief factors affecting the critical value have been demonstrated in the analysis.

N-42502*

NEUTRAL HOLES IN PLANE SHEET: REINFORCED HOLES WHICH ARE ELASTICALLY EQUIVALENT TO THE UNCUT SHEET. E. H. Mansfield. 1955. 34p. diagrs., photos., tab. (ARC R & M 2815; ARC 13,728. Supersedes RAE Structures 90)

In a plane sheet under any particular loading system, certain reinforced holes may be made which do not alter the stress distribution in the main body of the sheet. These reinforced holes necessarily have exactly the same stiffness and at least the same strength as the portion of the sheet that has been cut out. The weight of the reinforcement is usually greater than the weight of the sheet that has been cut out, though there are cases where it is less. The Airy stress function is used throughout because it admits of great generality and because the properties of a neutral hole can be expressed simply in terms of the function and its derivatives. Indeed, the stress function assumes a new and special significance in determining the shape of a neutral hole.

FLUTTER PROBLEMS OF HIGH-SPEED AIRCRAFT. E. G. Broadbent. 1955. 23p. diagrs., tabs. (ARC R & M 2828; ARC 12,398. Supersedes RAE Structures 37)

Flutter problems of high-speed aircraft are considered generally, and specific consideration is then given to new problems introduced by use of new wing plan forms. Theoretical and experimental results on the coupled ("classical") symmetrical flutter of swept (including "barbed" and cranked forms) and delta wings are reviewed and presented to show the effect and importance of body freedoms of aircraft on critical flutter speed and frequency. A criterion is proposed for deciding the "dangerous type" of fundamental normal mode to be considered in flutter calculations. The danger here is that the fundamental normal mode can combine with the body freedoms and give rise to a form of flutter which is independent of wing torsional stiffness. It is suggested that the deciding feature is the shape of the nodal line in the fundamental mode. If it is such as to indicate rotation of the fore-and-aft wing sections near the tip, then the mode is considered to be dangerous.

N-42504*

Aeronautical Research Council (Gt. Brit.)
HELICOPTER ROTOR BEHAVIOUR AFTER ENGINE FAILURE IN FORWARD FLIGHT. W. Stewart and M. F. Burle. 1955. 13p. diagrs., tab. (ARC R & M 2861; ARC 14,478. Supersedes RAE Tech. Note Aero 2119)

Calculations were made to find the changes in rotor speed following engine failure in forward flight. Several particular examples were investigated, based on the parameters of the S-51 helicopter. The effect of pilot's control movement was included. A rapid loss of rotational speed occurs with practically no change in forward speed of the helicopter, thus the tip-speed ratio increases rapidly. This may lead to stalling of the retreating blade and/or interference of the blades with the droop stops, either of which are dangerous conditions. The time available to the pilot to reduce the collective pitch after engine failure is very short throughout the speed range and engine failure constitutes a danger to safety on this type of helicopter. Some form of automatic pitch reduction or power failure warning system is necessary.

MISCELLANEOUS

N-41873

RECENT RESEARCH ON THE DETERMINATION OF NATURAL MODES AND FREQUENCIES OF AIRCRAFT WING STRUCTURES. John M. Hedgepeth. (Presented to Structures and Materials Panel of Advisory Group for Aeronautical Research and Development, Washington, D. C., April 1956). 29p. diagrs., photos., tabs.

Results of some recent theoretical and experimental studies of vibrations of aircraft wing structures are summarized and discussed. Assessment is made of the importance of various effects not usually included in the elementary theories of bending and torsion of box beams, such as transverse shear flexibility, shear lag, restraint of warping, longitudinal (rotary) inertia, and cross-sectional deformability. The substitute stringer method of incorporating the effects of shear lag into the analysis of box-beam vibration is outlined. Natural frequencies obtained experimentally from resonance tests of box-beam specimens are presented and compared with the results of theoretical calculations. Two recently developed methods of analysis of low-aspect-ratio wings are described.

N-41875

AERODYNAMIC THEORY AND ITS APPLICATION TO FLUTTER. I. E. Garrick. (Presented to Structures and Materials Panel of Advisory Group for Aeronautical Research and Development, Washington, D. C., April 1956). 38p. diagrs.

A survey is given of the present status of aerodynamic theory in relation to flutter analysis with a discussion of concepts implied in the structural and aerodynamical background. Applications of some recent developments in the theory of oscillating wings, offering promise for the flutter analysis of low-aspect-ratio wings, are indicated. Problems of the subsonic and supersonic speed ranges are included.

N-41948

DIVERGENCE OF DELTA AND SWEPT SURFACES IN THE TRANSONIC AND SUPERSONIC SPEED RANGES. Franklin W. Diederich. (Presented to Structures and Materials Panel of Advisory Group for Aeronautical Research and Development, Washington, D. C., April 1956). 58p. diagrs.

Divergence and other static aeroelastic phenomena of swept and delta surfaces are discussed in a qualitative sense. Conclusions are drawn that swept surfaces cannot normally diverge at transonic and supersonic speeds, but that delta wings may diverge in a predominantly chordwise mode at transonic speeds. A method, which in principle considers the deformation of the surface at all points, is outlined for calculating static aeroelastic phenomena of surfaces of low aspect ratio. Various means of modifying the simple-beam theory commonly used for analyses of static aeroelastic phenomena are discussed with the aim of improving its accuracy for surfaces of low aspect ratio.

FUNDAMENTALS OF TURBULENT HEAT TRANSFER. (Die Grundlagen des turbulenten Wärmeüberganges). H. Reichardt. February 1956. 50p. diagrs., tabs. (Trans. from Archiv für die gesamte Wärmetechnik, no. 6/7, 1951, p. 129-142)

The need exists for a representation of the turbulent heat transfer which is not a priori tied to hypothetical presuppositions, and where the facts already recognized are clearly distinguished from those as yet uninvestigated. The present treatise offers such a representation. Results of a study of completely continuous damping of the turbulent exchange in the proximity of the wall are included. Beyond this, general formulas are given which form the basis for a later investigation of the influence on the heat transfer of the dependence of the fluid characteristics on the temperature. In addition, the turbulent heat transfer at extremely low Prandtl numbers is treated.

N-43169*

ON CONVERGING AND DIVERGING FLOWS. (Sebamari oyobi hirogari nagare ni tsuite). Busuke Hudimoto. (1956). 10p. diagrs. (Trans. from Transactions of the Society of Mechanical Engineers of Japan, v. 14, no. 48, sec. 3, 1948, p. 1-4)

An experimental analysis was made of two-dimensional convergent and divergent flow. For the convergent flow, it was found that an increase in favorable pressure drop caused an increase in the laminar sublayer thickness, whereas an increase in adverse pressure gradient caused a decrease in this thickness. In the case of the divergent flow, relations were obtained between the divergence ratio of the stream and the static-pressure recovery.

NACA Rept. 1215

IMPINGEMENT OF CLOUD DROPLETS ON A CYLINDER AND PROCEDURE FOR MEASURING LIQUID-WATER CONTENT AND DROPLET SIZES IN SUPERCOOLED CLOUDS BY ROTATING MULTICYLINDER METHOD. R. J. Brun, W. Lewis, P. J. Perkins and J. S. Serafini. Appendix E: ALTERNATE METHOD OF REDUCING ROTATING MULTICYLINDER DATA. Paul T. Hacker. 1955. iv, 43p. diagrs., photos., tabs. (NACA Rept. 1215. Supersedes TN 2903; TN 2904; RM E53D23)

The amount of water impinging in droplet form, the area of impingement, and the rate of impingement per unit area on a cylinder surface are calculated from droplet trajectories and presented in terms of dimensionless parameters to cover a wide range of flight and atmospheric conditions. The rotating multicylinder method for in-flight determination of liquid-water content and droplet size is described, including the theory of operation, the apparatus required, the technique of obtaining data in flight, and detailed methods of calculating the results. Necessary charts and tables are presented.

NACA Rept. 1229

EXACT SOLUTIONS OF LAMINAR-BOUNDARY-LAYER EQUATIONS WITH CONSTANT PROPERTY VALUES FOR POROUS WALL WITH VARIABLE TEMPERATURE. Patrick L. Donoughe and John N. B. Livingood. 1955. ii, 21p. diagrs., tabs. (NACA Rept. 1229. Supersedes TN 3151)

Solutions were computed for a Prandtl number of 0.7 and a range of cooling-air flows, and pressure and wall temperature gradients. For each case, boundary-layer thicknesses and heat-transfer and friction coefficients were also computed and tabulated. Steeper temperature profiles for a given coolant flow were obtained by increased wall temperature gradients. Wall temperature gradients for zero boundary-layer temperature gradients at the wall were increased by increased pressure gradient and decreased by increased coolant flow.

NACA Rept. 1232

A THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE LIFT AND DRAG CHARACTERISTICS OF HYDROFOILS AT SUBCRITICAL AND SUPERCRITICAL SPEEDS. Kenneth L. Wadlin, Charles L. Shuford, Jr., and John R. McGehee. 1955. ii, 22p. diagrs., photos., tab. (NACA Rept. 1232. Supersedes RM L52D23a)

A theoretical and experimental investigation was made of the effect of the free-water surface and rigid boundaries on the lift and drag of an aspect-ratio-10 hydrofoil at both subcritical and supercritical speeds and of an aspect-ratio-4 hydrofoil at supercritical speeds. Approximate theoretical solutions for the effect of the free-water surface and rigid boundaries on lift and drag at supercritical speeds were developed. An approximate theoretical solution for the effect of these boundaries on drag at subcritical speeds was also presented. The agreement between theory and experiment at both supercritical and subcritical speeds is satisfactory for engineering calculations of hydrofoil characteristics from aerodynamic data.

NACA Rept. 1238

INVESTIGATIONS AT SUPERSONIC SPEEDS OF 22 TRIANGULAR WINGS REPRESENTING TWO AIRFOIL SECTIONS FOR EACH OF 11 APEX ANGLES. Eugene S. Love. 1955. ii, 60p. diagrs., photos., tabs. (NACA Rept. 1238. Supersedes RM L9D07)

The results of tests of 22 triangular wings, representing two leading-edge shapes for each of 11 apex angles, at Mach numbers of 1.62, 1.92, and 2.40 are presented and compared with theory. All wings have a common thickness ratio of 8 percent and a common maximum-thickness point at 18 percent chord. Lift, drag, and pitching moment are given for all wings at each Mach number. The relation of transition in the boundary layer, shocks on the wing surfaces, and characteristics of the pressure distributions is discussed for several wings.

ERROR IN AIRSPEED MEASUREMENT DUE TO THE STATIC-PRESSURE FIELD AHEAD OF AN AIRPLANE AT TRANSONIC SPEEDS. Thomas C. O'Bryan, Edward C. B. Danforth, and J. Ford Johnston. February 1956. 13p. diagrs., photos. (NACA Rept. 1239. Supersedes RM L9C25; RM L50L28; RM L52A17)

Measurements of static-pressure error ahead of sharp-nose bodies, open-nose air inlets, and ahead of the wing tip of a swept-wing fighter airplane model have been made at transonic speeds by use of the NACA wing-flow method.

NACA Rept. 1249

A UNIFIED TWO-DIMENSIONAL APPROACH TO THE CALCULATION OF THREE-DIMENSIONAL HYPERSONIC FLOWS, WITH APPLICATION TO BODIES OF REVOLUTION. A. J. Eggers, Jr. and Raymond C. Savin. 1955. ii, 27p. diagrs., tab. (NACA Rept. 1249. Supersedes TN 2811)

A procedure for calculating three-dimensional steady and nonsteady supersonic flows with the method of characteristics is developed and discussed. An approximate method is deduced from the characteristics method and shown to be of practical value at high supersonic speeds.

NACA Rept. 1250

THE DYNAMIC-RESPONSE CHARACTERISTICS OF A 35° SWEPT-WING AIRPLANE AS DETERMINED FROM FLIGHT MEASUREMENTS. William C. Triplett, Stuart C. Brown, and G. Allan Smith. 1955. ii, 25p. diagrs., tabs. (NACA Rept. 1250. Supersedes RM A51G27; RM A52I17)

Longitudinal and lateral directional dynamic-response characteristics of a 35° swept-wing fighter airplane are presented. Frequency responses, transfer functions, and stability derivatives are evaluated from flight measurements of airplane responses to abrupt elevator, rudder, and aileron motions through the Mach number range of 0.50 to 1.04. A graphical method for converting frequency-response data into transfer function form is discussed, and test results are compared to predictions based on wind-tunnel tests.

NACA RM L55G26a

A WIND-TUNNEL INVESTIGATION OF A 0.4-SCALE MODEL OF AN ASSAULT-TRANSPORT AIRPLANE WITH BOUNDARY-LAYER CONTROL APPLIED. Marvin P. Fink, Bennie W. Cocke, and Stanley Lipson. May 1956. 63p. diagrs., photos. (NACA RM L55G26a)

The results of an investigation made in the Langley full-scale tunnel to evaluate the lift, drag, and stability and control characteristics of a 0.4-scale model of an assault-transport airplane equipped with a boundary-layer-control system are presented. The boundary-layer-control system of this investigation utilized a single pump to suck air in over the inboard flap and to discharge the same air over the aileron through a blowing slot. Results include the effects of such variables as flap hinge position, suction slot design, quantity of air handled, flap deflection, and propeller operation on the lifting effectiveness of the boundary-layer-control system.

NACA TM 1369

FLAT PLATE CASCADES AT SUPERSONIC SPEED. (Ebene Plattengitter bei Überschallgeschwindigkeit). Rashad M. El Badrawy. May 1956. iii, 130p. diagrs., photos., tabs. (NACA TM 1369. Trans. of Eidgenössische Technische Hochschule Zürich. Institut für Aerodynamik. Mitteilungen 19)

A brief review of exact two-dimensional supersonic flow theory and Ackeret's linearized theory are first presented. The lift and drag coefficients of a cascade of flat plates are calculated exactly and compared to those obtained using the linearized theory. The forces on the cascade are determined for unsteady inlet flow. The flat plate cascade theory is extended to compute the efficiency of a supersonic propeller with friction and finite blade thickness.

NACA TM 1393

FLOW OF GAS THROUGH TURBINE LATTICES. M. E. Deich. May 1956. 136p. diagrs., photos. (NACA TM 1393. Trans. of Russian book: Technical Gasdynamics, ch. 7, 1953, p. 312-420)

This report is concerned with fluid mechanics of two-dimensional cascades, particularly turbine cascades. Methods of solving the incompressible ideal flow in cascades are presented. The causes and the order of magnitude of the two-dimensional losses at subsonic velocities are discussed. Methods are presented for estimating the flow and losses at high subsonic velocities. Transonic and supersonic flows in lattices are then analyzed. Some three-dimensional features of the flow in turbines are noted.

NACA TN 3546

EXPLORATORY INVESTIGATION OF BOUNDARY-LAYER TRANSITION ON A HOLLOW CYLINDER AT A MACH NUMBER OF 6.9. Mitchel H. Bertram. May 1956. 38p. diagrs., photo., tab. (NACA TN 3546)

The Reynolds number for transition on the outside of a hollow cylinder with heat transfer from the boundary layer to the wall has been investigated at a Mach number of 6.9 in the Langley 11-inch hypersonic tunnel. From consideration of only the results obtained in that portion of the nozzle which surveys indicated to have an essentially constant Mach number, the Reynolds number for the start of transition was between 4×10^6 and 6×10^6. From a correlation of results obtained from various sources at lower Mach numbers (in the range 2.0 to 4.5) leading-edge thickness and free-stream Reynolds number per inch appear to be important considerations in flat-plate transition results. At a given Mach number it appears that the Reynolds number based on leading-edge thickness is an important parameter that must be considered in comparisons of flat-plate transition data from various facilities.

NACA TN 3604

LOW-SPEED YAWED-ROLLING CHARACTERISTICS AND OTHER ELASTIC PROPERTIES OF A PAIR OF 26-INCH-DIAMETER, 12-PLY-RATING, TYPE VII AIRCRAFT TIRES. Walter B. Horne, Robert F. Smiley, and Bertrand H. Stephenson. May 1956. 98p. diagrs., photos., tabs. (NACA TN 3604)

The low-speed (up to 2 miles per hour) cornering characteristics of two 26 x 6.6, type VII, 12-ply-rating tires under straight-yawed rolling were determined over a range of inflation pressures and yaw angles for two vertical loads. The cornering characteristics of one tire rolling along circular paths of different radii were investigated for one condition of vertical load and inflation pressure. Static tests were also performed to determine the vertical, lateral, torsional, and fore-and-aft elastic characteristics of the tires. The quantities measured included lateral or cornering force, drag force, torsional moment or self-alining torque, pneumatic caster, vertical tire deflection, lateral tire deflection, wheel torsion or yaw angle, rolling radius, and relaxation length. Some supplementary tests were made which included measurements of tire footprint area and the variation of unloaded tire radius with inflation pressure.

NACA TN 3641

WIND-TUNNEL INVESTIGATION OF A NUMBER OF TOTAL-PRESSURE TUBES AT HIGH ANGLES OF ATTACK. SUBSONIC, TRANSONIC, AND SUPERSONIC SPEEDS. William Gracey. May 1956. 30p. diagrs., tabs. (NACA TN 3641)

The total-pressure errors of 54 total-pressure tubes at angles of attack up to 60° and Mach numbers from 0.26 to 1.62 are presented. The configurations of the various tubes differed as regards external shape, internal shape, and type of total-pressure entry. External shapes tested included cylindrical, conical, and ogival nose sections. Internal shapes and total-pressure entries were varied on the basis of such factors as size of impact openings, internal chamber shape, leading-edge slant profile, and shielding (combined with venting). The effect of these variables on the sensitivities of the tubes to angle of attack is presented.

NACA TN 3643

MEASUREMENT OF AERODYNAMIC FORCES FOR VARIOUS MEAN ANGLES OF ATTACK ON AN AIRFOIL OSCILLATING IN PITCH AND ON TWO FINITE-SPAN WINGS OSCILLATING IN BENDING WITH EMPHASIS ON DAMPING IN THE STALL. A. Gerald Rainey. May 1956. i, 66p. diagrs., photo. (NACA TN 3643)

The oscillating air forces on a two-dimensional wing oscillating in pitch about the midchord have been measured at various angles of attack and at Mach numbers of 0.35 and 0.7. Large regions of unstable damping in pitch were found. Measurements of the aerodynamic damping of a 10-percent-thick and a 3-percent-thick finite-span wing oscillating in, essentially, the first bending mode indicate no regions of unstable damping for this type of motion over the range of variables covered.

NACA TN 3647

INVESTIGATION OF THE COMPRESSIVE STRENGTH AND CREEP LIFETIME OF 2024-T ALUMINUM-ALLOY SKIN-STRINGER PANELS AT ELEVATED TEMPERATURES. Eldon E. Mathauser and William D. Deveikis. May 1956. 29p. diagrs., photos., tabs. (NACA TN 3647)

The experimental results of an investigation to determine compressive strength and creep lifetime of 2024-T (formerly 24S-T) aluminum-alloy skin-stringer panels at room temperature and at 400° F are presented. The results of strength tests at room temperature and 400° F are compared with predicted strength obtained from methods given in the literature for estimating crippling strength of short panels and for predicting column strength of longer panels. Creep lifetime curves are presented for four values of slenderness ratio and creep characteristics of the panels are discussed. A method which makes use of isochronous compressive stress-strain curves for predicting creep lifetime of panels is presented.

NACA TN 3648

INVESTIGATION OF BOUNDARY-LAYER TRANSITION ON 10° CONE IN LANGLEY 4- BY 4-FOOT SUPERSONIC PRESSURE TUNNEL AT MACH NUMBERS OF 1.41, 1.61, AND 2.01. Archibald R. Sinclair and K. R. Czarnecki. May 1956. 17p. diagrs., photos. (NACA TN 3648)

An investigation has been made to determine the transition Reynolds numbers on a 10° cone in the Langley 4- by 4-foot supersonic pressure tunnel at Mach numbers of 1.41, 1.61, and 2.01 and over a Reynolds number range from about 0.8×10^6 to 9.5×10^6 per foot. The results indicated that the transition Reynolds numbers increased with tunnel stagnation pressure and that there was no effect of Mach number on transition Reynolds numbers. A single-element surface roughness caused a larger decrease in transition Reynolds number than was experienced in low-speed or in other supersonic wind-tunnel investigations.

NACA TN 3692

INVESTIGATION AT ZERO FORWARD SPEED OF A LEADING-EDGE SLAT AS A LONGITUDINAL CONTROL DEVICE FOR VERTICALLY RISING AIRPLANES THAT UTILIZE THE REDIRECTED-SLIPSTREAM PRINCIPLE. Richard E. Kuhn. May 1956. 33p. diagrs., photos. (NACA TN 3692)

Results are presented of an investigation of a leading-edge slat as a longitudinal control device for vertically rising airplanes in hovering flight. The model consisted of a semispan wing equipped with a 60-percent-chord and a 30-percent-chord slotted flap operating in the slipstreams of two large-diameter propellers. The tests were conducted at zero speed in a large room. The results indicate that the slat can provide increments of pitching moment of the order of those required for trim and control in hovering flight. Also the leading-edge slat can appreciably reduce the adverse effects of the ground on the effectiveness of the slotted-flap wing in redirecting the slipstreams downward.

NACA TN 3693

PRELIMINARY INVESTIGATION OF THE EFFECTIVENESS OF A SLIDING FLAP IN DEFLECTING A PROPELLER SLIPSTREAM DOWNWARD FOR VERTICAL TAKE-OFF. Richard E. Kuhn and Kenneth P. Spreemann. May 1956. 25p. diagrs., photo. (NACA TN 3693)

Results are presented of an investigation of the effectiveness of a sliding flap in deflecting propeller slipstreams downward for vertical take-off. The model consisted of a semispan wing equipped with a 50-percent-chord sliding flap and a 25-percent-chord plain flap. The tests were conducted at zero forward speed in a large room and included the effects of flap deflection, proximity to the ground, a leading-edge slat, and a chord-extension. The results indicate that the diving moments associated with the sliding flap were appreciably smaller than those of the slotted-flap configuration previously investigated.

NACA TN 3714

A SONIC-FLOW ORIFICE PROBE FOR THE IN-FLIGHT MEASUREMENT OF TEMPERATURE PROFILES OF A JET ENGINE EXHAUST WITH AFTERBURNING. C. Dewey Havill and L. Stewart Rolls. May 1956. 18p. diagrs., photos. (NACA TN 3714)

A temperature-measuring system using two sonic-flow orifices in series is described. This system was adapted to measure the exhaust gas temperature of an afterburning jet engine and was mounted in a swinging pitot-static probe. The sonic-flow orifice system had only a small variation in temperature at the thermocouple and temperature change was measured as a change in pressure. Measurement of exhaust temperature of 3200° R was obtained during afterburner operation in flight.

Royal Aircraft Establishment (Gt. Brit.) LOW SPEED TUNNEL TESTS ON THE FLOW STRUCTURE BEHIND A BODY OF REVOLUTION OF FINENESS RATIO $16\frac{2}{3}$:1. A. Spence and W. J. G. Trebble. October 1955. 20p. diagrs. (RAE Tech. Note Aero 2406)

As part of a general program of tests to determine the low speed characteristics of supersonic designs, tests have been made on a body of revolution of fineness ratio $16\frac{2}{3}$:1, the shape being that giving minimum supersonic wave drag for a given fineness ratio and length. Wake traverses have been made at incidences of 10° and 20°, the former having a symmetrical pair of trailing vortices, and the latter an asymmetric flow. Surface pressure measurements have also been made in the symmetrical flow range, and the results analyzed to show the effect of viscosity on the normal force distribution.

Royal Aircraft Establishment (Gt. Brit.) THE ATMOSPHERIC STRESS-CORROSION OF ALUMINIUM-ZINC-MAGNESIUM TYPE ALLOYS. G. Meikle and D. Lewis. October 1955. 41p. diagrs., photos., tabs. (RAE Met. 88)

Variation of structure produced by heat treatment resulted in increased resistance to stress-corrosion. For extruded material containing chromium and stressed in the long transverse direction, improvement was produced by prolonging the aging time at 130° C, raising the aging temperature to 150° C, and by lowering the solution temperature to 435° C. The RR77 forged chromium-free alloy showed improvement by prolonged aging at 130° C and by increasing the aging temperature to 150° C. For both alloys stressed across end-grain the maximum susceptibility was produced after 32 hours aging at 130° C but longer periods indicated that improvement would result. Aging temperatures below 130° C gave poor results.

THE THEORETICAL DETERMINATION OF NORMAL MODES AND FREQUENCIES OF VIBRATION. I. T. Minhinnick. (To be presented to Structures and Materials Panel, Advisory Group for Aeronautical Research and Development, Washington, D. C., April 1956.) January 1956. 47p. diagrs. (RAE Structures 197)

In this paper the various methods that have been devised for the determination of the natural frequencies and normal modes of aircraft are discussed and their accuracy and the amount of work that they entail are compared. An extensive bibliography is given in an appendix. The discussion is mainly from the point of view of the flutter analyst, who commonly bases his analyses on the normal modes, but the description and comparison of the various methods should be of general interest.

THE RESPONSE TIME OF TRANSDUCTORS WITH NEGATIVE VOLTAGE FEEDBACK. F. D. Gill. December 1955. 18p. diagrs., tabs. (RAE Tech. Note EL 107)

The use of negative feedback in a transductor circuit reduces both power amplification and response time but not necessarily in the same proportion. Tests were performed to determine to what extent they are affected and to determine the response time when the feedback fraction is sufficient to reduce the voltage amplification to unity.

N-42641*

Royal Aircraft Establishment (Gt. Brit.)
THE HEATING EFFECT OF STEADY AND PULSED CURRENT IN RESISTANCE TRANDUCERS. K. R. Maslen and Mary Coulter. November 1955. 25p. diagrs., photo., tabs. (RAE Tech. Note Instn. 150)

It has been suggested that the output signal of resistance transducers might be increased by energizing them with pulsed input of very much higher voltage than is permissible for steady energization. An attempt is made in this note to determine to what extent such inputs may be increased without increasing the temperature rise in the transducer. Measurements have been made of the heating effect of steady and pulsed input in some unbonded transducers and other specimens, and a theoretical analysis is included. It is shown that, provided the period of energization is short compared with the time constant of heating of an unbonded transducer, the peak voltage may be increased to any extent which does not increase the mean power input to the transducer. The behavior of bonded transducers appears to be more complex, and further work is required to establish the safe conditions for them.

SOME EXPERIMENTS ON THE TITANIUM-CARBON SYSTEM. R. L. Bickerdike and G. Hughes. December 1955. 33p. diagrs., photos., tabs. (RAE Met. 89)

A vacuum quenching furnace for use up to 2100° C for short periods and up to at least 1800° C for long periods has been constructed. Using this equipment, the melting point of titanium and part of the titanium-carbon phase diagram have been determined. The melting point of titanium was found to be 1671 ± 8° C and the titanium-carbon system to have a eutectic at 1645 ± 8° C and about 1.14 percent carbon. The liquidus from the eutectic point up to 1763° C has been determined. Experiments were carried out on the rate of carbon pickup by molten titanium, and it is considered that diffusion in the liquid is probably the main rate controlling factor.

ON THE NATURE OF TURBULENT COMBUSTION. (O Prirode Turbulentnogo Goreniya). Y. B. Sviridov. (1956). 30p. diagrs. (Trans. from Akademiia Nauk SSSR, Izvestiia, Otdelenie Tekhnicheskikh Nauk, no. 11, 1953, p. 1577-1597)

The effect of turbulence on flame propagation rates is considered theoretically. Large- and small-scale turbulent combustion is classified as follows: (1) stationary and nonstationary combustion, (2) nonstationary combustion with point ignition and developed initial flame front, and (3) turbulent combustion with developed spectra of both isotropic and anisotropic turbulence. Equations relating the thickening of the combustion zone to the turbulent field characteristics are developed.

NACA RM A50E10

THE TRANSONIC CHARACTERISTICS OF A LOW-ASPECT-RATIO TRIANGULAR WING WITH A CONSTANT-CHORD FLAP AS DETERMINED BY WING-FLOW TESTS, INCLUDING CORRELATION WITH LARGE-SCALE TESTS. George A. Rathert, Jr., L. Stewart Rolls, and Carl M. Hanson. July 18, 1950. 39p. diagrs., photo. (NACA RM A50E10)

Wing-flow-method measurements are presented from 0.47 to 1.15 Mach number of the longitudinal stability and control characteristics of a triangular wing of aspect ratio 2 equipped with a constant-chord flap. Because of the low Reynolds number, 920,000 to 1,690,000, correlation with large-scale tests is used to study the effect on the significance of the data. The plan-form characteristics at transonic speeds showed moderate and gradual changes and were relatively unaffected by scale. The flap retained positive effectiveness at all speeds and flap angles.

NACA RM A50F06

LIFT AND PITCHING-MOMENT INTERFERENCE BETWEEN A POINTED CYLINDRICAL BODY AND TRIANGULAR WINGS OF VARIOUS ASPECT RATIOS AT MACH NUMBERS OF 1.50 AND 2.02. Jack N. Nielsen, Elliott D. Katzen, and Kenneth K. Tang. September 12, 1950. 53p. diagrs., photos., tabs. (NACA RM A50F06)

The lift and pitching-moment characteristics of a body alone, six triangular wings of various aspect ratios, and the combinations were measured at Mach numbers of 1.50 and 2.02 at a Reynolds number of 5.5 million (based on the body length). The total lift and pitching-moment interference were determined and compared with theory. The agreement was found to be good.

NACA RM A53E12

THE EFFECTS OF LEADING-EDGE EXTENSIONS, A TRAILING-EDGE EXTENSION, AND A FENCE ON THE STATIC LONGITUDINAL STABILITY OF A WING-FUSELAGE-TAIL COMBINATION HAVING A WING WITH 35° OF SWEEPBACK AND AN ASPECT RATIO OF 4.5. Ralph Selan and Angelo Bandettini. August 1953. 81p. diagrs., photos., tabs. (NACA RM A53E12)

Test results are presented to show the effects of various modifications including several leading-edge chord extensions, a trailing-edge extension, and a fence on the static longitudinal stability of a model having a wing with 35° sweepback, an aspect ratio 4.5, and a taper ratio 0.5. The tests were conducted at various Mach numbers up to 0.92 at a Reynolds number of 2 million, and at a Mach number of 0.20 at a Reynolds number of 11 million.

NACA RM A54E10

EFFECTS OF HIGH-LIFT DEVICES AND HORIZONTAL-TAIL LOCATION ON THE LOW-SPEED CHARACTERISTICS OF A LARGE-SCALE 45° SWEPT-WING AIRPLANE CONFIGURATION. Ralph L. Maki and Ursel R. Embry. August 1954. 46p. diagrs., photo., tabs. (NACA RM A54E10)

An investigation was made of a 45° swept-wing model of aspect ratio 3.5 and taper ratio 0.3 with high-lift devices designed to delay the occurrence of stalled flow to a wing-lift coefficient of 1.4 at 14° angle of attack. Unstable pitching moments after stalled flow began were largely controlled by locating the horizontal tail in the extended wing-chord plane.

NACA RM A54G13

INVESTIGATION OF THE NACA 4-(5)(05)-037 SIX- AND EIGHT-BLADE, DUAL-ROTATION PROPELLERS AT POSITIVE AND NEGATIVE THRUST AT MACH NUMBERS UP TO 0.90, INCLUDING SOME AERODYNAMIC CHARACTERISTICS OF THE NACA 4-(5)(05)-041 TWO- AND FOUR-BLADE, SINGLE-ROTATION PROPELLERS. John H. Walker and Robert M. Reynolds. October 1954. 148p. diagrs., photos., tabs. (NACA RM A54G13)

Presented are the results of tests in the Ames 12-foot pressure tunnel for a wide range of propeller blade angles and forward speeds. Limited comparisons show the effects of total solidity, of spinner shape, and of blade-angle differential between the front and rear units of the dual propeller. Included are the results of tests of the propellers at near static conditions.

NACA RM E6L06

PERFORMANCE OF A 20-INCH STEADY-FLOW RAM JET AT HIGH ALTITUDES AND RAM-PRESSURE RATIOS. Eugene Perchonok, William H. Sterbentz, and Fred A. Wilcox. June 25, 1947. 39p. diagrs., photos. (NACA RM E6L06)

The investigation was conducted in the Cleveland altitude wind tunnel at altitudes ranging from 7000 to 41,500 feet and at ram-pressure ratios equivalent to free-stream Mach numbers as great as 1.84 using preheated 62-octane fuel. Supplementary tests to determine any change in performance caused by changing the fuel to preheated 100-octane were also made. An extension of the methods of data reduction and of the generalizing performance parameters applicable at supersonic Mach numbers and over a wide range of operating conditions is presented. The magnitudes of the total-pressure losses across the various phases of the ram-jet cycle are analyzed and discussed.

NACA RM E7I05a

FLIGHT INVESTIGATION OF A 20-INCH-DIAMETER STEADY-FLOW RAM JET. John H. Disher. January 14, 1948. 29p. diagrs., photo. (NACA RM E7I05a)

A flight investigation was conducted on a 20-inch steady-flow ram jet. The ram jet was studied in flight at altitudes from 5,000 to 30,000 feet and free-stream Mach numbers up to 0.51. A range of fuel-air ratios from 0.013 to 0.11 and combustion-chamber-inlet velocities up to 154 feet per second were covered. Data were obtained on flame stability and combustion efficiency for these conditions.

NACA RM E8D22

INVESTIGATION OF EFFECTS OF MOVABLE EXHAUST-NOZZLE PLUG ON OPERATIONAL PERFORMANCE OF 20-INCH RAM JET. William H. Sterbentz and Fred A. Wilcox. July 27, 1948. 32p. diagrs., photos. (NACA RM E8D22)

Effects of a movable exhaust-nozzle plug on the operational performance of a 20-inch ram jet were determined in an investigation conducted in the Cleveland altitude wind tunnel. Incorporation of the nozzle plug into the combustion chamber of the ram jet improved the combustion efficiency of the engine. The negligible effect of the exhaust-nozzle plug on the net thrust per square foot of exhaust-nozzle area indicated that the total-pressure losses over the exhaust-nozzle plug were small.

PERFORMANCE OF A RAM-JET-TYPE COMBUSTOR WITH FLAME HOLDERS IMMERSED IN THE COMBUSTION ZONE. Roland Breitwieser. November 1, 1948. 47p. diagrs., photos. (NACA RM E8F21)

A performance comparison was made between a conventional single-row ram-jet burner and burners embodying one, two, and three rows of gutters immersed in the combustion zone. The stepwise addition of rows of wedges immersed in the combustion zone regularly extended the stability limits of combustion. The maximum allowable inlet-air velocity for the four-row configuration was approximately twice the inlet-air velocity of the conventional single-row configuration.

DESIGN FACTORS FOR 4- BY 8-INCH RAM-JET COMBUSTOR. Donald W. Male and Adolph J. Cervenka. August 11, 1949. 47p. diagrs., photos. (NACA RM E9F09)

An investigation was made of a series of flame holders designed with objective of providing high combustion efficiency in a 4- by 8-inch ram-jet combustor 24 inches long at inlet-air velocity of 200 feet per second, inlet-air pressure of 60 inches mercury absolute, inlet-air temperature of 200° F, and near stoichiometric fuel-air ratio. The most efficient and stable combustor designs investigated employed fuel injection directly at upstream end of flame holder that combined surfaces heated to incandescence by immersion in flame with continuous path of low stream velocity for flame propagation between upstream and downstream ends of flame holder. Silicon-coated molybdenum was satisfactorily used as flame-holder material at high temperatures encountered.

NACA RM E9F20

INVESTIGATION OF INTERNAL REGENERATIVE FUEL-HEATING SYSTEM FOR 20-INCH RAM JET. Sol Baker and Eugene Perchonok. September 1, 1949. 22p. diagrs., photos. (NACA RM E9F20)

A test-stand investigation was undertaken to evaluate the effectiveness of a simple internal regenerative fuel preheater for a 20-inch-diameter ram jet. Data obtained at subsonic sea-level conditions indicate that the fuel can be successfully preheated in this manner. The distance the preheater was located downstream of the flame holder is the primary variable affecting the final fuel temperature. The additional pressure loss caused by the introduction of the preheater in the combustion chamber may be considered negligible.

NACA RM E9F22

FREE-FLIGHT PERFORMANCE OF 16-INCH-DIAMETER SUPERSONIC RAM-JET UNITS. I - FOUR UNITS DESIGNED FOR COMBUSTION-CHAMBER-INLET MACH NUMBER OF 0.12 AT FREE-STREAM MACH NUMBER OF 1.6 (UNITS A-2, A-3, A-4, AND A-5). William W. Carlton and Wesley E. Messing. September 22, 1949. 51p. diagrs., photos. (NACA RM E9F22)

Free-flight investigations were conducted on four 16-inch-diameter ram-jet units to determine the performance at high subsonic and supersonic velocities. The effects of free-stream Mach number and gas total-temperature ratio on diffuser total-pressure recovery, thrust coefficient, and external-drag coefficient are correlated. Performance data of individual ram-jet units were obtained over a range of free-stream Mach numbers from 0.38 to 1.73 and for gas total-temperature ratios between 1.0 and 6.6.

NACA RM E9H12

EXPERIMENTAL INVESTIGATION OF PRESSURE FLUCTUATIONS IN 3.6-INCH RAM JET AT MACH NUMBER 1.92. James F. Connors and Albert H. Schroeder. October 13, 1949. 20p. diagrs., photos. (NACA RM E9H12)

From experiments on 3.6-inch ram jet at Mach number 1.92, pressure-fluctuation amplitudes based on single-point instantaneous measurements are presented as function of fuel-air ratio for several outlet-inlet area ratios. With both burner configurations at optimum mean combustion-chamber static pressure, maximum instantaneous pressure coincided with static pressure at optimum cold recovery. With conical flame-holder configuration, minimum instantaneous pressure at optimum mean pressure recovery approximated cold static pressure corresponding to particular outlet area. Fundamental frequency varied from 6 to 35 cycles per second. Improved diffuser performance was realized with regenerative-type burner as compared with perforated conical flame-holder configuration.

NACA RM E9H19

ANALYSIS AND EXPERIMENTAL OBSERVATION OF PRESSURE LOSSES IN RAM-JET COMBUSTION CHAMBERS. William H. Sterbentz. November 4, 1949. 22p. diagrs. (NACA RM E9H19)

Analyses were made to determine the effect of primary variables on pressure losses resulting from flame-holder drag and heat addition in a ram-jet combustion chamber. From a sudden-expansion flow-area theory, an estimate of flame-holder pressure-drop coefficient was made that may be used in the design or performance estimation of ram jets. Experimental data on combustion-chamber pressure losses due to heat addition were obtained from wall-static-pressure measurements and indicated a deviation of pressure-drop coefficient as high as 1.31 times the one-dimensional theoretical value.

NACA RM E9L09

COOLING OF RAM JETS AND TAIL-PIPE BURNERS - ANALYTICAL METHOD FOR DETERMINING TEMPERATURES OF COMBUSTION CHAMBER HAVING ANNULAR COOLING PASSAGE. William K. Koffel, Eugene Stamper, and Newell D. Sanders. March 21, 1950. 51p. diagrs., tab. (NACA RM E9L09)

An analytical method is given for calculating the maximum wall temperature of a tail-pipe burner or a ram-jet combustion chamber cooled by air or gas flowing through a surrounding annular passage. An empirical equation is developed, which expresses the outlet cooling-gas temperature in terms of known conditions of flow and geometry. When the outlet cooling-gas temperature is known, two parameters can be evaluated that make possible the determination of the maximum temperature of the inside wall from a working chart, which solves the heat balance across the inside wall at the outlet.

NACA RM E50I06

FREE-JET PERFORMANCE OF 16-INCH RAM-JET ENGINE WITH SEVERAL FUELS. Fred A. Wilcox. October 31, 1950. 23p. diagrs., photos. (NACA RM E50I06)

Gasoline (AN-F-48b), kerosene (AN-F-32), isopentane, a blend (by volume) of 50-percent gasoline plus 50-percent propylene oxide, and a blend (by volume) of 75-percent kerosene plus 25-percent propylene oxide were used in a 16-inch ram jet during a free-jet investigation of ram-jet performance in the Lewis altitude wind tunnel. Maximum ranges of operation were obtained with the blends of propylene oxide. Gasoline gave minimum values of weight specific fuel consumption, whereas kerosene gave minimum values of volume specific fuel consumption.

NACA RM E51C12

PRELIMINARY EVALUATION OF THE AIR AND FUEL SPECIFIC-IMPULSE CHARACTERISTICS OF SEVERAL POTENTIAL RAM-JET FUELS. I - OCTENE-1, ALUMINUM, AND ALUMINUM - OCTENE-1 SLURRIES. Benson E. Gammon. April 30, 1951. 20p. diagrs. (NACA RM E51C12)

A preliminary analytical evaluation of the air and fuel specific-impulse characteristics of octene-1, aluminum, and aluminum - octene-1 slurries has been made. Adiabatic constant pressure combustion flame temperatures for each fuel at several equivalence ratios were calculated for an initial air temperature of 560° R and a pressure of 2 atmospheres.

NACA RM E51D25

PRELIMINARY EVALUATION OF THE AIR AND FUEL SPECIFIC-IMPULSE CHARACTERISTICS OF SEVERAL POTENTIAL RAM-JET FUELS. III - DIBORANE, PENTABORANE, BORON, AND BORON-OCTENE-1 SLURRIES. Benson E. Gammon. July 1951. 26p. diagrs. (NACA RM E51D25)

A preliminary analytical evaluation of the air and fuel specific-impulse characteristics of diborane, pentaborane, boron, and boron - octene-1 slurries has been made. Adiabatic constant-pressure combustion flame temperatures for each fuel at several equivalence ratios were calculated for an initial air temperature of 560° R and a pressure of 2 atmospheres.

NACA RM E51E01

PERFORMANCE CHARACTERISTICS OF AIRCRAFT COOLING EJECTORS HAVING SHORT CYLINDRICAL SHROUDS. Fred D. Kochendorfer and Morris D. Rousso. May 22, 1951. 39p. diagrs. (NACA RM E51E01)

The factors affecting the performance of ejectors suitable for aircraft cooling are investigated both theoretically and experimentally. The investigation covers a range of shroud-to-nozzle diameter ratios from 1.1 to 1.6, of shroud lengths from 0.2 to 2.28 nozzle diameters, of secondary-to-primary weight-flow ratios from 0 to 0.12, and of ambient-to-nozzle pressure ratios from 0.7 to 0.06. For low values of the ratio of the jet ambient pressure to the primary total pressure, the performance of ejectors can be adequately explained by the methods of nonviscous fluid mechanics. Mixing effects can be neglected.

NACA RM E51F05

PRELIMINARY EVALUATION OF THE AIR AND FUEL SPECIFIC-IMPULSE CHARACTERISTICS OF SEVERAL POTENTIAL RAM-JET FUELS. IV - HYDROGEN, α-METHYLNAPHTHALENE, AND CARBON. Benson E. Gammon. August 1951. 22p. diagrs. (NACA RM E51F05)

A preliminary analytical evaluation of the air and fuel specific-impulse characteristics of hydrogen, α-methylnaphthalene, and graphite carbon has been made. Adiabatic constant-pressure combustion flame temperatures for each fuel at several equivalence ratios were calculated for an initial air temperature of 560° R and a pressure of 2 atmospheres.

NACA RM E51H02

ANALYTICAL INVESTIGATION OF RAM-JET ENGINE PERFORMANCE IN FLIGHT MACH NUMBER RANGE FROM 3 TO 7. Philip J. Evans, Jr. October 1951. 29p. diagrs. (NACA RM E51H02)

An analytical investigation was made of the performance of isolated ram-jet engines in the flight Mach number range from 3 to 7 for two types of diffuser, a high-efficiency diffuser, and a normal-shock diffuser. The fuel was assumed to be a hydrocarbon similar to gasoline. The conclusions reached are: (1) a design altitude of about 100,000 feet is desirable for a high-efficiency high Mach number ram jet on the basis of engine construction and performance; and (2) although greater thrust could be obtained with other fuels, gasoline provides sufficient energy release for maximum engine efficiency in the flight Mach number range investigated. The maximum engine efficiency calculated was 0.47, which occurred at a Mach number of 5. At a Mach number of 7, the maximum propulsive-thrust coefficient was 0.57.

NACA RM E52D08

EFFECT OF FUEL-AIR DISTRIBUTION ON PERFORMANCE OF A 16-INCH RAM-JET ENGINE. A. J. Cervenka and E. E. Dangle. June 1952. 25p. diagrs., photos., tab. (NACA RM E52D08)

The effect of combustion on diffusion in the fuel preparation zone of a 16-inch ram-jet engine was determined. The eddy diffusion coefficients were found to vary from 0.6 square foot per second for no burning in the engine to 1.6 square feet per second with burning. This information was applied in the design of a combustor to operate at lean fuel-air ratios. Operation to a lean fuel-air ratio limit of 0.007 was accomplished with the use of a cylindrical sleeve which limited fuel-air mixing upstream of the flame holder.

NACA RM E52E05

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. I - AERODYNAMIC DESIGN PROCEDURE. Walter M. Osborn and Joseph T. Hamrick. September 1952. 42p. diagrs., photo., tab. (NACA RM E52E05)

A mixed-flow impeller was designed with special emphasis upon the reduction or elimination of velocity decelerations along the wetted surface, especially along the blade suction surface. With the use of a provisional hub-shroud profile, the blade shape at the blade mean height was determined from a prescribed velocity distribution. The blade shape at all other locations was fixed by the introduction of radial blade elements and blade taper which were specified in consideration of stress requirements. The variation in flow conditions from hub to shroud and changes in the hub-shroud profile required to obtain the desired flow rate were investigated by an analysis in the hub-shroud plane in which axially symmetrical flow was assumed. The method was extended to obtain the blade surface-velocity distribution for a finite number of blades. In order to allow for viscous effects and to increase the blade-height-to-passage-width ratio, the blade height was arbitrarily increased and splitter vanes were added. Preliminary experimental results show that an impeller designed by this procedure with allowances for viscous effects had higher than average efficiency and good operating characteristics.

NACA RM E52E21

PRELIMINARY AIR-FLOW AND THRUST CALIBRATIONS OF SEVERAL CONICAL COOLING-AIR EJECTORS WITH A PRIMARY TO SECONDARY TEMPERATURE RATIO OF 1.0. I - DIAMETER RATIOS OF 1.21 AND 1.10. W. K. Greathouse and D. P. Hollister. July 1952. 24p. diagrs. (NACA RM E52E21)

An investigation of the performance of several conical cooling-air ejectors was made at primary jet pressure ratios from 1 to 10, secondary shroud

pressure ratios from 0.60 to 4.00, and a primary to secondary temperature ratio of 1.0. Primary air flow, secondary air flow, primary nozzle thrust, and gross ejector thrust were measured. The data are presented in terms of secondary to primary weight-flow ratio and gross ejector to primary nozzle thrust ratio. This phase of the investigation was limited to ejectors having shroud-exit to primary-nozzle-exit diameter ratios of 1.21 and 1.10 with several spacing ratios for each. The experimental results indicated that for an ejector having a given diameter ratio the spacing ratio for maximum thrust was considerably less than the spacing ratio for maximum pumping. The smaller-diameter-ratio ejector produced less thrust loss at secondary pressure ratios below 1.00 than did the large-diameter-ratio ejector. The data indicated that significant losses in gross thrust will occur if the cooling-air flow is controlled by throttling in the upstream secondary flow passage.

NACA RM E52E22

DESIGN AND TEST OF MIXED-FLOW IMPELLERS. II - EXPERIMENTAL RESULTS, IMPELLER MODEL MFI-1A. Joseph R. Withee, Jr., and William L. Beede. September 1952. 28p. diagrs., photos., tab. (NACA RM E52E22)

An investigation was conducted to determine the performance characteristics of a mixed-flow impeller which was designed with special emphasis on the reduction or elimination of flow decelerations along the wetted surfaces. The performance was investigated over a range of equivalent impeller speeds from 700 to 1600 feet per second and over a range of flow rates from maximum to point of incipient surge. The peak pressure ratio and maximum adiabatic temperature-rise efficiency, measured at 1-1/2 impeller diameters in a vaneless diffuser, at the design speed of 1400 feet per second were 4.00 and 0.83, respectively.

NACA RM E52E27

INFILTRATION OF TITANIUM CARBIDE WITH SEVERAL METALS. Raymond S. Gurnick and Anthony L. Cooper. July 1952. 21p. diagrs., photos. (NACA RM E52E27)

An investigation was made to determine the applicability of infiltration techniques for producing ceramals of titanium carbide with various metals or alloys. Nickel, S-816, Stellite 21 (AMS-5385), Hastelloy B, and Stellite 93 were used as infiltrant materials. Specimens for elevated-temperature modulus-of-rupture and stress-rupture testing, and turbosupercharger blades, were fabricated by infiltrating titanium carbide with S-816 alloy. Turbosupercharger blades were also fabricated by arc-welding or precision-casting of alloy roots to infiltrated ceramal airfoils by means of titanium carbide and S-816 alloy. The ceramal composed of titanium carbide and S-816 had a modulus-of-rupture strength of more than 100,000 pounds per square inch at 1600° F and 54,000 pounds per square inch at 1800° F. The stress-rupture life was 1082 hours at 1500° F and 112 hours at 1600° F at a stress of 15,000 pounds per square inch.

NACA RM E52E28

PRELIMINARY INVESTIGATION OF FLOW FLUCTUATIONS DURING SURGE AND BLADE ROW STALL IN AXIAL-FLOW COMPRESSORS. Merle C. Huppert. August 1952. 52p. diagrs., photos. (NACA RM E52E28)

A preliminary investigation of the flow fluctuations of surge and blade row stall was conducted with three single-stage axial-flow compressors with hub-tip ratios of 0.9, 0.8, and 0.5 and with a multistage axial-flow compressor. Flow fluctuations of large amplitude associated with stall were detected in all compressors investigated. The fluctuations were caused by low flow regions affecting 25 to 40 percent of the annulus area and propagating in the direction of compressor rotation, but at a lower speed. Mild audible surge was obtained with the single-stage compressors with hub-tip ratios of 0.9 and 0.8. No audible surge was detected with the 0.5 hub-tip ratio stage. A severe audible surge was obtained with the multistage axial-flow compressor. The surge point was coincident with the sharp drop in pressure ratio due to stall.

NACA RM E52F26

PRELIMINARY AIR-FLOW AND THRUST CALIBRATIONS OF SEVERAL CONICAL COOLING-AIR EJECTORS WITH A PRIMARY TO SECONDARY TEMPERATURE RATIO OF 1.0. II - DIAMETER RATIOS OF 1.06 AND 1.40. W. K. Greathouse and D. P. Hollister. August 1952. 35p. diagrs. (NACA RM E52F26)

An investigation was made of the performance of nine conical cooling-air ejectors at primary jet pressure ratios from 1 to 10, secondary pressure ratios to 4.0, and a temperature ratio of unity. This phase of the investigation was limited to conical ejectors having shroud-exit to primary-nozzle-exit diameter ratios of 1.06 and 1.40, with several spacing ratios for each. The experimental results indicated that the pumping range and amount of cooling-air flow obtained with a 1.06-diameter-ratio ejector were relatively small for cooling purposes but that the maximum possible thrust loss, which occurred with no secondary flow, was only 7 percent of convergent-nozzle thrust. The 1.40-diameter-ratio ejector produced a large cooling-air flow and showed a possible thrust loss of 29.5 percent with no cooling-air flow. Thrust gains were attained with ejectors of both diameter ratios at secondary pressure ratios greater than 1.0. The limiting primary pressure ratio below which an ejector can operate at a specific secondary pressure ratio (cut-off point) may be estimated for various flight conditions from data contained herein.

NACA RM E52I23

COMBUSTION EFFICIENCY OF HOMOGENEOUS FUEL-AIR MIXTURES IN A 5-INCH RAM-JET-TYPE COMBUSTOR. Thaine W. Reynolds and Robert D. Ingebo. November 1952. 36p. diagrs., tabs. (NACA RM E52I23)

Combustion-efficiency data have been obtained for a 5-inch-diameter ram-jet-type combustor with a straight V-gutter flame holder and a simple cone flame holder with gasoline, isopentane, benzene, and propylene oxide. The data cover a range of inlet static pressures from 2 to 0.5 atmospheres, inlet temperatures from 100° F to 300° F, and inlet velocivelocities from 170 to 300 feet per second. A correlation of the data is presented and is shown to be in agreement with a propagation mechanism based on the concept that the rate of flame propagation through an unburned mixture is a function of the fundamental flame speed.

NACA RM E53C20

EFFECT OF FUELS ON COMBUSTION EFFICIENCY OF 5-INCH RAM-JET-TYPE COMBUSTION. Thaine W. Reynolds. May 1953. 40p. diagrs., tabs. (NACA RM E53C20)

Combustion-efficiency data were obtained for a 5-inch ram-jet-type combustor employing a simple V-gutter flame holder. The data, which are for homogeneous fuel-air mixtures of 14 pure fuels and 2 fuel blends, cover a range of inlet static pressures and velocities. The data are shown to correlate with the following parameter for all of the fuels tested except carbon disulfide:

$$\frac{P^{0.3}T}{V^{0.8}}\left(\frac{U_f}{U_{ref}}\right)^{1.1}$$

where P is the inlet pressure in atmospheres, T is the inlet temperature in °R, V is the inlet velocity in feet per second, U_f is the maximum fundamental flame velocity in feet per second, and U_{ref} is the maximum fundamental flame velocity of the reference fuel in feet per second. This relation was arrived at experimentally and also analytically from an assumption that the combustion proceeded by an increase of the flame-front area through turbulence in the combustor and that the flame propagated at the fundamental flame speed of the fuel-air mixture.

NACA RM L50G17a

TRANSONIC FLIGHT TESTS TO COMPARE THE ZERO-LIFT DRAG OF UNDERSLUNG AND SYMMETRICAL NACELLES VARIED CHORDWISE AT 40 PERCENT SEMISPAN OF A 45° SWEPTBACK, TAPERED WING. William B. Pepper, Jr., and Sherwood Hoffman. October 25, 1950. 36p. diagrs., photos., tabs. (NACA RM L50G17a)

Rocket-powered models were flown at transonic speeds to determine the effect of nacelle location on the zero-lift drag. Solid nacelles were mounted in underslung and symmetrical (midwing) positions and varied chordwise at the 40-percent-semispan station of a 45° sweptback, tapered wing. From these tests it is apparent that the drag increment associated with adding nacelles to a wing-body combination is largely dependent upon the nacelle location.

NACA RM L50H08

A TRANSONIC-WING INVESTIGATION IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL AT HIGH SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. WING-FUSELAGE CONFIGURATION WITH A WING OF 45° SWEEPBACK, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. Robert S. Osborne. October 10, 1950. 49p. diagrs., photos. (NACA RM L50H08)

A wing-fuselage combination employing a wing with 45° sweepback of the 0.25-chord line, aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil section parallel to the plane of symmetry was tested at high subsonic Mach numbers and at a Mach number of 1.2 to determine its force, moment, wake, and downwash characteristics.

NACA RM L50H10

INITIAL FLIGHT INVESTIGATION OF A TWIN-ENGINE SUPERSONIC RAM JET. Maxime A. Faget and H. Rudolph Dettwyler. September 15, 1950. 28p. diagrs., photos. (NACA RM L50H10)

A flight investigation was made of a supersonic twin-ram-jet test vehicle using short-flame-length burners. The test demonstrated a maximum acceleration of 3.6g and a maximum flight Mach number of 3.02. Data were obtained over a Mach number range from about 1.9 to 3.0, an altitude range from 1,800 to 40,900 feet, and a fuel-air-ratio range from 0.012 to 0.065.

NACA RM L50J09

A TRANSONIC WING INVESTIGATION IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL AT HIGH SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. WING-FUSELAGE CONFIGURATION HAVING A WING OF 35° SWEEPBACK, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. Beverly Z. Henry, Jr. November 15, 1950. 40p. diagrs., photo., tab. (NACA RM L50J09)

Lift, drag, and pitching-moment characteristics, wake characteristics, and downwash angles are presented for a wing-fuselage configuration employing a wing with quarter-chord line swept back 35°, an aspect ratio of 4, a taper ratio of 0.6, and an NACA 65A006 airfoil section. Results are presented for various angles of attack at high subsonic Mach numbers and at a Mach number of 1.2.

NACA RM L50L06

FREE-JET TESTS OF A 6.5-INCH-DIAMETER RAM-JET ENGINE AT MACH NUMBERS OF 1.81 AND 2.00. Maxime A. Faget, Raymond S. Watson, and Walter A. Bartlett, Jr. March 7, 1951. 38p. diagrs., photos. (NACA RM L50L06)

Results of free-jet tests of a ram-jet engine at Mach numbers of 1.81 and 2.00, together with a method for evaluation of the performance, are presented. A range of fuel-air ratios from 0.015 to 0.100 was tested. The effects on the engine performance of changes in free-stream temperature are included. The results are compared with flight tests of the engine.

NACA RM L51B23

TABULATED PRESSURE COEFFICIENTS AND AERODYNAMIC CHARACTERISTICS MEASURED ON THE WING OF THE BELL X-1 AIRPLANE IN AN UNACCELERATED STALL AND IN PULL-UPS AT MACH NUMBERS OF 0.74, 0.75, 0.94, AND 0.97. Lawrence A. Smith. June 19, 1951. 49p. diagrs., photo., tabs. (NACA RM L51B23)

Presents tabulated pressure coefficients and aerodynamic characteristics measured on the wing of the Bell X-1 research airplane in an unaccelerated stall and in pull-ups at Mach numbers of approximately 0.74, 0.75, 0.94, and 0.97.

NACA RM L51F13

COMPARISON OF ZERO-LIFT DRAGS DETERMINED BY FLIGHT TESTS AT TRANSONIC SPEEDS OF SYMMETRICALLY MOUNTED NACELLES IN VARIOUS CHORDWISE POSITIONS AT THE WING TIP OF A 45° SWEPTBACK WING AND BODY COMBINATION. William B. Pepper, Jr., and Sherwood Hoffman. September 1951. 16p. diagrs., photos. (NACA RM L51F13)

The effect on drag at transonic speeds of varying the chordwise location of a nacelle at the wing tip of a 45° sweptback wing and body combination has been determined by use of rocket-propelled models at zero lift. The drag of the wing-body-fin configuration was reduced near $M = 1.0$ by adding nacelles at the wing tips.

NACA RM L51K02

TRANSONIC FLIGHT TESTS TO DETERMINE ZERO-LIFT DRAG AND PRESSURE RECOVERY OF NACELLES LOCATED AT THE WING TIPS ON A 45° SWEPTBACK WING AND BODY COMBINATION. Sherwood Hoffman and William B. Pepper, Jr. January 1952. 21p. diagrs., photos., tabs. (NACA RM L51K02)

The zero-lift drag of a high-aspect-ratio 45° sweptback wing and body combination with nacelles having the NACA 1-50-250 nose inlet located at the wing tips was determined by flight tests of rocket-propelled models at transonic speeds. The inlet pressure recovery at transonic speeds was determined from flight tests and at supersonic speeds by preflight jet tests.

NACA RM L51L18

FREE-JET TESTS OF A 1.1-INCH-DIAMETER SUPERSONIC RAM-JET ENGINE. Joseph H. Judd and Otto F. Trout, Jr. March 1952. 24p. diagrs., photos., tabs. (NACA RM L51L18)

Results of free-jet tests of a 1.1-inch-diameter hydrogen-burning ram-jet engine over a Mach number range of 1.42 to 2.28 and a Reynolds number range of 6.01×10^6 to 15.78×10^6 are presented. Tests demonstrated the reliability and wide operating range of the engine and showed its suitability for installation on wind-tunnel models of airplane and missile configurations. A comparison of engine operation with combustion-chamber lengths of 3.33 and 1.51 engine diameters was made at a Mach number of 2.06. A maximum test thrust coefficient of 0.905 was obtained at fuel-air ratio of 0.034 and a Mach number of 2.06 for the engine with the 3.33-diameter combustion chamber.

NACA RM L51L27

TRANSONIC FLIGHT TESTS TO COMPARE THE ZERO-LIFT DRAGS OF 45° SWEPTBACK WINGS OF ASPECT RATIO 3.55 AND 6.0 WITH AND WITHOUT NACELLES AT THE WING TIPS. Sherwood Hoffman and Richard C. Mapp, Jr. March 1952. 17p. diagrs., photos. (NACA RM L51L27)

The zero-lift drags of 45° sweptback wings of aspect ratio 3.55 and 6.0 with and without solid nacelles at the wing tips were determined from flight tests of rocket-propelled models at transonic speeds. The wing-tip nacelle location was found favorable from a drag standpoint.

NACA RM L52D24

FLIGHT MEASUREMENTS AT MACH NUMBERS FROM 1.1 TO 1.9 OF THE ZERO-LIFT DRAG OF A TWIN-ENGINE SUPERSONIC RAM-JET CONFIGURATION. Abraham Leiss. June 1952. 16p. diagrs., photos. (NACA RM L52D24)

A flight investigation was conducted to determine the zero-lift drag of a twin-engine supersonic ram-jet configuration having a fineness ratio of 23.69. Two vehicles were tested - one with nacelles and one without nacelles. The test covered a Mach number range from 0.7 to 1.9 and a Reynolds number range from 20×10^6 to 1.18×10^6. The external drag of the nacelles was 60 percent of the total external drag of the configuration and the fuselage and fins accounted for the other 40 percent.

NACA RM L52E06

EFFECTS OF STABILIZING FINS AND A REAR-SUPPORT STING ON THE BASE PRESSURES OF A BODY OF REVOLUTION IN FREE FLIGHT AT MACH NUMBERS FROM 0.7 TO 1.3. Roger G. Hart. September 1952. 19p. diagrs., photos., tab. (NACA RM L52E06)

Isolated fuselages were flight-tested at Mach numbers from 0.7 to 1.3 in order to determine the contributions of the body and the fin-body interference to the total drag of previously tested combinations. A rear-support sting similar to those used in wind tunnels was tested with one of the fuselages.

#NACA RM L52E07a

NACA RM L52E13

EFFECT OF FUSELAGE INTERFERENCE ON THE DAMPING IN ROLL OF DELTA WINGS OF ASPECT RATIO 4 IN THE MACH NUMBER RANGE BETWEEN 0.6 AND 1.6 AS DETERMINED WITH ROCKET-PROPELLED VEHICLES. William M. Bland, Jr. July 1952. 13p. diagrs., photos. (NACA RM L52E13)

The effect of fuselage-diameter - wing-span ratio on the damping-in-roll characteristics of a delta wing of aspect ratio 4 with 4-percent-thick symmetrical double-wedge airfoil sections was investigated in the Mach number range between 0.6 and 1.6 by a technique which used rocket-propelled vehicles in free flight. It is shown that the damping-in-roll derivative decreased when the fuselage-diameter - wing-span ratio was increased from 0 to 0.4 and then to 0.6; furthermore, it is shown that the experimental results agree with theory.

NACA RM L52E29

A CORRELATION WITH FLIGHT TESTS OF RESULTS OBTAINED FROM THE MEASUREMENT OF WING PRESSURE DISTRIBUTIONS ON A 1/4-SCALE MODEL OF THE X-1 AIRPLANE (10-PERCENT-THICK WING). Jack F. Runckel and James H. Henderson. September 1952. 60p. diagrs., photos., tab. (NACA RM L52E29)

A comparison of wing pressure-distribution measurements obtained on a 1/4-scale model in a slotted wind tunnel with results from flight tests of the X-1 airplane is presented. Results were obtained through a Mach number range from 0.70 to 1.00 at Reynolds numbers up to 4.6 million and at angles of attack up to 15° at lower speeds and up to 5° at $M = 1.00$.

NACA RM L53D23

FLOW DIFFUSION IN A CONSTANT-DIAMETER DUCT DOWNSTREAM OF AN ABRUPTLY TERMINATED CENTER BODY. Charles C. Wood and James T. Higginbotham. July 1953. 27p. diagrs. (NACA RM L53D23)

A preliminary investigation of the flow properties of a constant-outer-wall annular diffuser in combination with a tailpipe has been conducted for the purpose of obtaining qualitative information which might lead to a short efficient configuration applicable to turbojet afterburners. The diffuser has an outer diameter of 21 inches, and area ratio of 1.9:1, and a 180° overall equivalent conical angle of expansion. Tests were conducted with fully developed pipe flow with and without vortex generators, with axial flow and with 20.6° whirling inlet flow, up to a maximum inlet Mach number of 0.33 and a corresponding Reynolds number of 1.06×10^6. With axial flow, a vena contracta region is formed rendering the first 1/2 diameter of tailpipe length ineffective. The introduction of whirl in the inlet flow suppresses the vena contracta resulting in a 170-percent gain in static-pressure rise and a 28-percent reduction in total-pressure loss. The installation of vortex generators has little effect on the vena contracta for axial flow and removes the favorable effect of whirl.

NACA RM L53E06

EFFECTS OF HORIZONTAL-TAIL HEIGHT AND A WING LEADING-EDGE MODIFICATION CONSISTING OF A FULL-SPAN FLAP AND A PARTIAL-SPAN CHORD-EXTENSION ON THE AERODYNAMIC CHARACTERISTICS IN PITCH AT HIGH SUBSONIC SPEEDS OF A MODEL WITH A 45° SWEPTBACK WING. William D. Morrison, Jr. and William J. Alford, Jr. June 1953. 37p. diagrs., photo., tab. (NACA RM L53E06)

The effects of horizontal-tail height (13.9 percent wing semispan below and 13.9 and 25.6 percent semispan above chord plane extended) on the pitch characteristics of a general-research model having full-span wing leading-edge deflection and a partial-span chord-extension have been determined at Mach numbers of 0.40 through 0.93 at Reynolds numbers ranging from about 2,000,000 to 3,000,000. Lift, drag, and pitching moments were determined, for three horizontal tail angles, at all Mach numbers investigated for angles of attack ranging from -2° to 24° except at the higher Mach numbers where tunnel choking restricted this angle range.

NACA RM L53E19

WIND-TUNNEL INVESTIGATION TO DETERMINE THE HORIZONTAL- AND VERTICAL-TAIL CONTRIBUTIONS TO THE STATIC LATERAL STABILITY CHARACTERISTICS OF A COMPLETE-MODEL SWEPT-WING CONFIGURATION AT HIGH SUBSONIC SPEEDS. James W. Wiggins, Richard E. Kuhn, and Paul G. Fournier. July 1953. 34p. diagrs., photo. (NACA RM L53E19)

Results are presented of an investigation made in the Langley high-speed 7- by 10-foot tunnel to determine the horizontal- and vertical-tail contributions to the static lateral stability of a complete-model configuration. The general research model was tested through a Mach number range from 0.40 to 0.95 and an angle-of-attack range from -3° to 25° at angles of sideslip of $\pm 4^{\circ}$.

NACA RM L53E20

WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS IN PITCH OF WING-FUSELAGE COMBINATIONS AT HIGH SUBSONIC SPEEDS. TAPER-RATIO SERIES. Thomas J. King, Jr. and Thomas B. Pasteur, Jr. June 1953. 37p. diagrs., photos., tab. (NACA RM L53E20)

This paper presents the aerodynamic characteristics of wing-fuselage combinations of aspect ratio 4, sweepback angle of 45°, and taper ratios of 0.3, 0.6, and 1.0. The tests covered a Mach number range from 0.4 to 0.95 at Reynolds numbers of 2,000,000 to 3,000,000 and an angle-of-attack range from -2° to 26°.

NACA RM L53E20a

COMPARISON OF LIFT-CURVE SLOPES FOR A MODEL TESTED IN TWO SLOTTED TUNNELS OF DIFFERENT SIZES AT HIGH SUBSONIC SPEEDS. Robert W. Boswinkle, Jr. June 1953. 13p. diagrs. (NACA RM L53E20a)

The boundary effects on an 18-inch span, 60° triangular wing model tested in the 26-inch Langley transonic blowdown tunnel are shown to cause only small decreases in the lift-curve slopes from those obtained with the same model in the Langley 8-foot transonic tunnel; the decreases amount to less than 0.001 per degree and 0.003 per degree at Mach numbers of 0.80 and 0.975, respectively. The theory of a previously published paper, although not exactly applicable to the present case, gave corrections to the lift-curve slopes obtained in the smaller tunnel which appeared to be of the correct sign and of the proper order of magnitude.

NACA RM L53E26

A COLLECTION OF DATA FOR ZERO-LIFT DAMPING IN ROLL OF WING-BODY COMBINATIONS AS DETERMINED WITH ROCKET-POWERED MODELS EQUIPPED WITH ROLL-TORQUE NOZZLES. David G. Stone. July 1953. 23p. diagrs., tab. (NACA RM L53E26)

Zero-lift damping-in-roll data have been collected from experimentally determined results through high subsonic, transonic, and low supersonic speeds by a torque-nozzle forced-roll technique utilizing rocket-propelled models. These data collections show the effects of wing plan form and airfoil section, and, qualitatively, the effects of wing aeroelasticity and show all wings tested to have damping in roll in this speed range at 0° angle of attack.

NACA RM L53E26a

PRELIMINARY RESULTS OF SUPERSONIC-JET TESTS OF SIMPLIFIED WING STRUCTURES. Richard R. Heldenfels and Richard Rosecrans. July 1953. 19p. diagrs., photos. (NACA RM L53E26a)

Seven small multiweb wing structures were tested under simulated supersonic flight conditions to investigate the structural effects of aerodynamic heating. Three models experienced chordwise flutter and failure; the other four incorporated structural modifications that prevented flutter. The tests are discussed and the conclusion is reached that the models failed as a result of the combined action of aerodynamic heating and loading.

NACA RM L53E27

TEST OF AN AERODYNAMICALLY HEATED MULTIWEB WING STRUCTURE (MW-1) IN A FREE JET AT MACH NUMBER 2. Richard R. Heldenfels, Richard Rosecrans, and George E. Griffith. July 1953. 37p. diagrs., photos. (NACA RM L53E27)

A mulitweb wing structure, representing an airplane or missile wing, was tested under simulated supersonic flight conditions to determine the transient temperature distribution. The aerodynamic loads played an important and unanticipated role, however, in that the model experienced a dynamic failure near the end of the test. The test is discussed and the conclusion reached that the model failed as a result of the combined action of aerodynamic heating and loading. The temperature data collected are analyzed and shown to be in reasonable agreement with calculated values.

NACA RM L53E27a

TRANSIENT TEMPERATURE DISTRIBUTION IN AN AERODYNAMICALLY HEATED MULTIWEB WING. George E. Griffith. July 1953. 10p. diagrs. (NACA RM L53E27a)

Transient skin and interior temperatures are presented for a multiweb wing tested at Mach number 1.99. Four methods involving various degrees of approximation are used to calculate the temperatures; the results are shown to be in good agreement with the experimental temperatures when the significant types of heat conduction are taken into account.

NACA RM L53L24b

PRELIMINARY INVESTIGATION AT SUBSONIC AND TRANSONIC SPEEDS OF THE AERODYNAMIC CHARACTERISTICS OF A BIPLANE COMPOSED OF A SWEPTBACK AND A SWEPTFORWARD WING JOINED AT THE TIPS. Jones F. Cahill and Dexter H. Stead. March 1954. 19p. diagrs., photos. (NACA RM L53L24b)

Results are presented of a preliminary investigation of a swept biplane configuration composed of a sweptback and a sweptforward wing joined at the tips. The aspect ratio is defined on the basis of the total area of both wings. Lift, drag, and pitching moments are presented for Mach numbers of 0.2, 0.76, and 0.90 for a Reynolds number of approximately 2×10^6. Drag data for low lift coefficients are shown for transonic Mach numbers from 0.7 to 1.27 at a Reynolds number of approximately 1.0×10^6. Effective dihedral data are presented for several angles of attack at a Mach number of 0.8.

NACA RM L54E03a

STRESSES AND DEFLECTIONS OF A SWEPT BIPLANE WING. George W. Zender and John E. Duberg. August 1954. 41p. diagrs., photo., tabs. (NACA RM L54E03a)

The results of experimental and theoretical structural studies of a solid swept biplane wing composed of a sweptback front wing and a sweptforward rear wing joined at the tip are compared.

NACA RM L54E13

LONGITUDINAL STABILITY AND DRAG CHARACTERISTICS OF A FIN-STABILIZED BODY OF REVOLUTION WITH A FINENESS RATIO OF 12 AS MEASURED BY THE FREE-FALL METHOD. Max C. Kurbjun. June 1954. 19p. diagrs., photos., tab. (NACA RM L54E13)

Measurements were made of the longitudinal stability and drag characteristics of a fin-stabilized body of revolution with a fineness ratio of 12 at low angles of attack by the free-fall method. The Mach numbers ranged from subsonic to 1.26 and the normal-force coefficients from 0.11 to 0.24. Analysis indicates that the instability of the body decreases more rapidly with increasing normal-force coefficient than the theory of NACA RM A9I26 predicts. The difference in the investigation results and theory is assumed to be attributable to the effect of the increase in Mach number which accompanied the increase in normal-force coefficient. Longitudinal force measurements agreed favorably at subsonic speeds and were 20 percent less at supersonic speeds than the zero-lift drag of NACA RM L9J27.

NACA RM L54E19

SOME INTERNAL-FLOW CHARACTERISTICS AT ZERO FLIGHT SPEED OF AN ANNULAR SUPERSONIC INLET AND AN OPEN-NOSE INLET WITH SHARP AND ROUNDED LIPS. Joseph R. Miliillo. July 1954. 23p. diagrs., photo. (NACA RM L54E19)

A conical-shock inlet and open-nose inlet with three lip shapes were investigated at zero flight speed. Measurements of pressure recovery, surface pressure, total pressure, and mass flow are presented. The pressure recovery and choking mass-flow ratio were greatly improved by replacing the sharp lip by two alternate shapes with lip roundness or internal contraction just behind the leading edge. It was found that inlets with thin sharp lips had similar pressure-recovery characteristics which were adequately defined by theory.

NACA RM L54E19a

SOME INTERNAL-FLOW CHARACTERISTICS OF SEVERAL AXISYMMETRICAL NACA 1-SERIES NOSE AIR INLETS AT ZERO FLIGHT SPEED. Carroll R. Bryan and Frank F. Fleming. July 1954. 30p. diagrs., photos. (NACA RM L54E19a)

Six 8-inch-diameter NACA 1-series nose inlets (one with protruding central body) were tested at zero forward velocity. Presented are total-pressure surveys, pressure-recovery measurements, and flow visualization studies at mass flows from below the normal operating range to choking. Parameters were found which define choking mass flow and choking average total-pressure ratio for inlets whose inner lip geometry is related to those tested.

NACA RM L54E20

INVESTIGATION OF A CANARD MISSILE CONFIGURATION (NACA RM-4) IN THE LANGLEY 9-INCH SUPERSONIC TUNNEL AT MACH NUMBERS OF 1.62 AND 1.93. Carl E. Grigsby. June 1954. 24p. diagrs., photo. (NACA RM L54E20)

An investigation was made in the Langley 9-inch supersonic tunnel of a canard missile configuration designated the NACA RM-4 configuration. Measurements of lift, drag, and pitching moment were made over an angle-of-attack range of -5° to 15° at Mach numbers of 1.62 and 1.93. Breakdown tests were made at a Mach number of 1.62 for several roll angles. For the complete configuration, the deflections of the canard fins and the angle of roll were varied at both Mach numbers. The configuration was tested with the canard fins inline and with the canard fins interdigitated 45° with respect to the wings. The data are presented without analysis.

NACA RM L54J28

VIBRATORY-STRESS INVESTIGATION OF SIX- AND EIGHT-BLADE DUAL-ROTATING PROPELLERS OPERATING AT ZERO ADVANCE. Atwood R. Heath, Jr. and Robert L. O'Neal. February 1955. 26p. diagrs., photo., tabs. (NACA RM L54J28)

An investigation of the vibratory stresses of a dual-rotating propeller of both six- and eight-blade configurations has been made on the NACA 6,000-horsepower propeller dynamometer at the Langley propeller static test stand. The investigation covered a range of blade angle from 4° to 36° and a range of rotational speed from 600 rpm to 2,200 rpm. The propeller-blade vibratory stresses caused by mutual interference of the propeller blades are presented as well as the vibratory stresses resulting from other causes.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1223

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF HEAT TRANSFER BY LAMINAR NATURAL CONVECTION BETWEEN PARALLEL PLATES. A. F. Lietzke. 1955. ii, 7p. diagrs. (NACA Rept. 1223. Supersedes TN 3328)

For the experimental work, parallel walls (one heated uniformly and the other cooled uniformly) were simulated by an annulus with an inner-to-outer diameter ratio near 1. The theoretical results are presented in equations for the velocity and temperature profiles and the ratio of actual temperature drop across the fluid to temperature drop for pure conduction. No experimental measurements were made of the velocity and temperature profiles, but the experimental results are compared with theory on the basis of the ratio of the actual temperature drop to the temperature drop for pure conduction. Good agreement was obtained between theory and experiment for axial temperature gradients above 40^{0} F/ft.

NACA Rept. 1231

NACA TRANSONIC WIND-TUNNEL TEST SECTIONS. Ray H. Wright and Vernon G. Ward. 1955. ii, 38p. diagrs., photos., tabs. (NACA Rept. 1231. Supersedes RM L8J06)

An approximate subsonic theory has been developed for the solid blockage in a circular wind tunnel with walls slotted in the direction of flow. In tests of a tunnel based on this theory, a prediction of the theory regarding the possibility of practical elimination of the interference due to solid blockage has been realized. Choking limitations did not occur in the slotted tunnel, and it could be operated with continuous Mach number variation up to low supersonic Mach numbers merely by varying the power. Pressure distributions over the surface of a nonlifting model in the slotted tunnel were compared with those obtained over the same model in a much larger tunnel where the interference was negligible.

NACA Rept. 1233

SHOCK-TURBULENCE INTERACTION AND THE GENERATION OF NOISE. H. S. Ribner. 1955. iii, 19p. diagrs., tab. (NACA Rept. 1233. Supersedes TN 3255)

Interaction of convected field of turbulence with shock wave is analyzed to yield modified turbulence, entropy spottiness, and noise generated downstream of the shock. Analysis is generalization of single-spectrum-wave treatment of TN 2864. Formulas for spectra and correlations are obtained. Numerical calculations yield curves of rms velocity components, temperature, pressure, and noise in db against Mach number for $M = 1$ to ∞; both isotropic and strongly axisymmetric (lateral/longitudinal = 36/1) initial turbulence are treated. In either case, turbulence of 0.1 percent longitudinal component generates about 120 dbs of noise.

NACA Rept. 1240

AN INVESTIGATION OF THE EFFECTS OF HEAT TRANSFER ON BOUNDARY-LAYER TRANSITION ON A PARABOLIC BODY OF REVOLUTION (NACA RM-10) AT A MACH NUMBER OF 1.61. K. R. Czarnecki and Archibald R. Sinclair. 1955. 11p. diagrs., photos., tab. (NACA Rept. 1240. Supersedes TN 3165 and TN 3166)

This report presents the results of an investigation of the effects of heat transfer on boundary-layer transition on a parabolic body of revolution (NACA RM-10). This report includes also a study of the effectiveness of cooling on boundary-layer transition with the model surface roughened and with tunnel disturbances impinging on the model. The tests were made at a Mach number of 1.6 and over a Reynolds number range from 2.5×10^{6} to 35×10^{6}. A comparison is made between the experimental results and theory.

NACA Rept. 1253

A CORRELATION BY MEANS OF TRANSONIC SIMILARITY RULES OF EXPERIMENTALLY DETERMINED CHARACTERISTICS OF A SERIES OF SYMMETRICAL AND CAMBERED WINGS OF RECTANGULAR PLAN FORM. John B. McDevitt. 1955. ii, 23p. diagrs., tabs. (NACA Rept. 1253. Supersedes RM A51L17b; RM A53G31)

The transonic similarity rules have been used to correlate the experimental lift, drag, and pitching-moment data, obtained by use of the transonic bump

technique, for a series of 40 rectangular wings having NACA 63A0XX, 63A2XX, and 63A4XX sections, aspect ratios from 1/2 to 6, and thicknesses from 2 to 10 percent. The usefulness of certain alternative forms of the transonic similarity parameters was investigated and a range of validity for slender-body theory was demonstrated.

NACA RM 56C20

CORRELATION OF CREEP-BUCKLING TESTS WITH THEORY. Sharad A. Patel, Joseph Kempner, Burton Erickson, and Abol H. Mobassery, Polytechnic Institute of Brooklyn. May 1956. 39p. diagrs., photos., tabs. (NACA RM 56C20)

Results are presented of short-time creep-buckling and creep-bending tests of 2024-T4 aluminum-alloy columns of slenderness ratio 111. The tests were performed at 600° F, and strain measurements were made with high-temperature electric-resistance strain gages. The development of the gages is described in an appendix. The bending results are used together with a previously derived creep-buckling theory to develop a semiempirical formula suitable as a guide for determining the critical time for columns.

NACA RM A55L14

PRELIMINARY REPORT ON A STUDY OF SEPARATED FLOWS IN SUPERSONIC AND SUBSONIC STREAMS. Dean R. Chapman, Donald M. Kuehn, and Howard K. Larson. June 1956. 15p. diagrs., photos. (NACA RM A55L14)

Some results are described of fundamental research conducted on various flow separation phenomena in two-dimensional streams. Experimental and theoretical results are described for the pressure rise across a reattachment region, and for the Reynolds number dependence of the pressure rise to a separation point. Observations are made throughout of the location of transition relative to reattachment and to separation, since this relative location turned out to be the dominant variable investigated.

NACA RM E56C02

PRELIMINARY INVESTIGATION OF SHORT TWO-DIMENSIONAL SUBSONIC DIFFUSERS. Richard R. Woollett. May 1956. 19p. diagrs., photos., tab. (NACA RM E56C02)

The designs which were tested over a range of throat Mach numbers from 0.3 to 0.9, incorporated an effective diffusion angle of approximately 30° and an area ratio of 3. Included were: (1) a 30° faired diffuser with four variations of screens and vanes, (2) a diffuser in which the longitudinal velocity distribution is a step function and which utilizes suction early in the diffusion process, and (3) a vortex-trap design incorporating flow injection and suction. At a throat Mach number of 0.7, the resulting profile distortion of the unmodified 30° diffuser was diminished from about 11 to approximately 4 percent by use of any of the configurations.

NACA TM 1400

BOUNDARY LAYER. (Pogranichnyi sloi). L. G. Loitsianskii. May 1956. 29p. (NACA TM 1400. Trans. from Mechanics in the U.S.S.R. over Thirty Years, 1917-1947, p. 300-320)

The author reviews the scope of papers on boundary layer contained in seventy references for the period from 1917 to 1948.

NACA TN 3274

SOME LINEAR DYNAMICS OF TWO-SPOOL TURBOJET ENGINES. David Novik. June 1956. 35p. diagrs. (NACA TN 3274)

Transfer functions, descriptive of the responses of inner- and outer-spool speed to changes in turbine-inlet temperature and exhaust-nozzle area, were derived analytically and corroborated experimentally. The speed responses of both spools to a change in turbine-inlet temperature appeared as identical first-order lags, specified by the inner-spool time constant. The response to exhaust-nozzle area was characterized by a first-order lag response of the outer-spool, specified by the outer-spool time constant, accompanied by virtually no change in inner-spool speed.

NACA TN 3578

INFLUENCE OF LARGE AMPLITUDES ON FLEXURAL MOTIONS OF ELASTIC PLATES. George Herrmann, Columbia University. May 1956. 45p. diagrs. (NACA TN 3578)

A nonlinear plate theory of motion, valid for large deflections, is developed and discussed in the light of other theories. The influence of large rotations is demonstrated by solution of the resulting equations for the case of straight-crested waves. A study is made of the origin of certain terms appearing in nonlinear plate theories.

NACA TN 3580

STALL PROPAGATION IN AXIAL-FLOW COMPRESSORS. Alan H. Stenning, Anthony R. Kriebel, and Stephen R. Montgomery, Massachusetts Institute of Technology. June 1956. 83p. diagrs., photos., tab. (NACA TN 3580)

A theory for the prediction of the stall propagation velocity in axial-flow compressors has been developed and compared with experiments on a stationary circular cascade and a single-stage compressor. The theory, which is valid for small perturbations in velocity about a mean flow condition with finite pressure rise across the cascade, includes the effects of finite blade chord and boundary-layer response to changes in angle of attack.

NACA TN 3632

CORRELATION, EVALUATION, AND EXTENSION OF LINEARIZED THEORIES FOR TIRE MOTION AND WHEEL SHIMMY. Robert F. Smiley. June 1956. iv, 139p. diagrs., tab. (NACA TN 3632)

An evaluation is made of the existing theories of linearized tire motion and wheel shimmy. It is demonstrated that most of the previously published theories represent varying degrees of approximation to a summary theory developed herein which is a minor modification of the basic theory of Von Schlippe and Dietrich. In most cases where strong differences exist between the previously published theories and the summary theory, it is shown that the previously published theories are of inferior merit. A series of systematic approximations to the summary theory is developed for the treatment of problems too simple to merit the use of the complete summary theory and procedures are discussed for applying the summary theory and its systematic approximations to the shimmy of more complex landing-gear structures than have previously been considered. Comparisons of the existing experimental data with the predictions of the summary and systematic approximation theories provide a fair substantiation of the higher approximate theories.

NACA TN 3639

APPROXIMATE INDICIAL LIFT FUNCTIONS FOR SEVERAL WINGS OF FINITE SPAN IN INCOMPRESSIBLE FLOW AS OBTAINED FROM OSCILLATORY LIFT COEFFICIENTS. Joseph A. Drischler. May 1956. 26p. diagrs., tab. (NACA TN 3639)

The unsteady-lift functions for a wing undergoing a sudden change in sinking speed are presented for delta wings having aspect ratios of 0, 2, and 4 and for rectangular and elliptical wings with aspect ratios of 0, 3, and 6. For the elliptical and rectangular wings the local lift functions are also presented. These functions were calculated from the lift coefficients associated with a wing oscillating harmonically in pure translational motion.

NACA TN 3640

A METHOD FOR DEFLECTION ANALYSIS OF THIN LOW-ASPECT-RATIO WINGS. Manuel Stein and J. Lyell Sanders, Jr. June 1956. 65p. diagrs. (NACA TN 3640)

A method is presented for obtaining influence coefficients for thin low-aspect-ratio wings of built-up construction. Chordwise deflections are assumed to be parabolic (or linear) and the principle of minimum potential energy is used to obtain an appropriate set of equilibrium equations. A simple method is given for taking account of attachment to a flexible fuselage. The computations involved are for the most part organized into matrix form so as to be suitable for high-speed computing machines. The matrices needed at the beginning of the computing process can be set up directly from the data of the wing design.

NACA TN 3649

STATIC LONGITUDINAL AND LATERAL STABILITY CHARACTERISTICS AT LOW SPEED OF UNSWEPT-MIDWING MODELS HAVING WINGS WITH AN ASPECT RATIO OF 2, 4, OR 6. Walter D. Wolhart and David F. Thomas, Jr. May 1956. 41p. diagrs., photos., tabs. (NACA TN 3649)

An experimental investigation was made at low speed in the Langley stability tunnel to determine the static longitudinal and lateral stability characteristics of unswept-midwing models having wings with an aspect ratio of 2, 4, or 6 through an angle-of-attack range from -4° to 32°. The results indicate that the decrease in the tail contribution to longitudinal stability for wing-on configurations at low and moderate angles of attack increases with decreasing wing aspect ratio. There is a decrease in the tail contribution to directional stability at moderate and high angles of attack because of wing-fuselage interference at the tail which is counteracted by a stable shift in the directional stability of all wing-fuselage combinations investigated.

NACA TN 3671

WIND-TUNNEL INVESTIGATION OF THE EFFECT OF CLIPPING THE TIPS OF TRIANGULAR WINGS OF DIFFERENT THICKNESS, CAMBER, AND ASPECT RATIO - TRANSONIC BUMP METHOD. Horace F. Emerson. June 1956. 183p. diagrs., photo., tabs. (NACA TN 3671. Supersedes RM A53L03)

Transonic aerodynamic characteristics are presented for four basic triangular wings having aspect ratios of 2.0, 2.5, 3.0, and 4.0, and for these wings when their tips were progressively clipped to provide taper ratios of 0.1, 0.2, 0.3, 0.4 and in some cases 0.5. The NACA 63A00X profile was used with thickness-to-chord ratios of 0.02, 0.04, and 0.06. In addition, a wing with the NACA 63A(1.5)04 section was tested for each aspect ratio investigated. The Mach number range extended from 0.60 to 1.10, corresponding to a test Reynolds number range from 1.85 million to 2.90 million. Lift, drag, and pitching-moment coefficients are presented for each of the wings.

NACA TN 3673

ON THE RANGE OF APPLICABILITY OF THE TRANSONIC AREA RULE. John R. Spreiter. May 1956. 21p. diagrs. (NACA TN 3673. Supersedes RM A54F28)

Some insight into the range of applicability of the transonic area rule has been gained by comparison with the appropriate similarity rule of transonic flow theory and with experimental data for a large family of rectangular wings having NACA 63AXXX profiles.

NACA TN 3676

INVESTIGATION OF LATERAL CONTROL NEAR THE STALL. FLIGHT TESTS WITH HIGH-WING AND LOW-WING MONOPLANES OF VARIOUS CONFIGURATIONS. Fred E. Weick and H. Norman Abramson, Agricultural and Mechanical College of Texas. June 1956. 34p. diagrs., photos., tabs. (NACA TN 3676)

Flight tests were made with typical light airplanes to investigate possibilities for obtaining reliable lateral control at low flight speeds. The maximum angle of attack below the stall at which control is still available was determined for each airplane, as well as the elevator deflection required to trim at this condition, with power off and on, and to make a three-point landing. One airplane was tested with different horizontal tail configurations in an attempt to provide an arrangement that would give near-optimum conditions with regard to the effect of power change on longitudinal trim near the stall.

NACA TN 3677

INVESTIGATION OF LATERAL CONTROL NEAR THE STALL. ANALYSIS FOR REQUIRED LONGITUDINAL TRIM CHARACTERISTICS AND DISCUSSION OF DESIGN VARIABLES. Fred E. Weick and H. Norman Abramson, Agricultural and Mechanical College of Texas. June 1956. 91p. diagrs., tabs. (NACA TN 3677)

Analytical design procedures for estimating the elevator deflection required to trim in steady longitudinal flight are presented. Pertinent data and formulas for use in evaluating longitudinal trim characteristics are summarized from existing literature and two light airplanes are analyzed quantitatively to illustrate the use of the methods and to provide a comparison with flight-test results. Calculated values of elevator deflection for both airplanes are presented to demonstrate the quantitative effects of changes in some of the more important design parameters.

NACA TN 3681

INVESTIGATION OF PLASTIC BEHAVIOR OF BINARY ALUMINUM ALLOYS BY INTERNAL-FRICTION METHODS. R. E. Maringer, L. L. Marsh, and G. K. Manning, Battelle Memorial Institute. June 1956. 44p. diagrs., tabs. (NACA TN 3681)

The relationship between internal friction and plastic deformation in binary aluminum alloys was investigated, with the percentage of alloying element taken as a variable parameter. The effects of strain rate, amount of strain, heat treatment, temperature, and testing frequency on internal friction during plastic deformation were also studied. The experimental observations are analyzed in light of modern dislocation theory.

NACA TN 3685

FATIGUE CRACK PROPAGATION IN SEVERELY NOTCHED BARS. W. S. Hyler, E. D. Abraham, and H. J. Grover, Battelle Memorial Institute. June 1956. 31p. diagrs., photos., tabs. (NACA TN 3685)

Fatigue tests were made in rotating bending on severely notched bars machined from 2024-T4 aluminum-alloy extruded round rods. Two sizes of specimens were studied, 1/4-inch-diameter and 2-inch-diameter specimens. The smaller specimens were notched with a V-groove and had notch severities K_t of 5.2. The larger specimens also contained V-grooves with notch severities of 5.2 and 13.9.

NACA TN 3687

SOME WIND-TUNNEL EXPERIMENTS ON SINGLE-DEGREE-OF-FREEDOM FLUTTER OF AILERONS IN THE HIGH SUBSONIC SPEED RANGE. Sherman A. Clevenson. June 1956. 32p. diagrs., photo., tabs. (NACA TN 3687. Supersedes RM L9B08)

Results of tests of three wing models with various aileron configurations are presented. Density had little effect on the initial magnitude or initial Mach number of buzz. Buzz frequency decreased with decrease in density. Initial buzz Mach number decreased with increasing angle of attack. Mass balancing and changes of spring stiffness of the ailerons in these tests had little effect on buzz. Increasing the aileron mass moment of inertia lowered the buzz frequency. Placing the aileron at the wing tip delayed the onset of buzz. A comparison of the test results with two empirical analyses is made.

NACA TN 3696

A STUDY OF THE HIGH-SPEED PERFORMANCE CHARACTERISTICS OF 90° BENDS IN CIRCULAR DUCTS. James T. Higginbotham, Charles C. Wood, and E. Floyd Valentine. June 1956. 28p. diagrs. (NACA TN 3696)

Four 90° bends in ducts of constant diameter with ratios of radius of curvature to diameter (r/d) of 0.75, 1.00, 2.50, and 4.00 have been investigated with both a thin and a thick inlet boundary layer to determine the choke Mach number and general performance of each of the elbows. Inlet-boundary-layer thickness had a very small detrimental effect on the choking Mach number and practically no effect on the losses through the elbows. The elbow with $r/d = 2.50$ gave the greatest value of inlet choking Mach number and the least static-pressure loss and total-pressure loss.

NACA TN 3697

FLIGHT TESTS AT SUPERSONIC SPEEDS TO DETERMINE THE EFFECT OF TAPER ON THE ZERO-LIFT DRAG OF SWEPTBACK LOW-ASPECT-RATIO WINGS. Murray Pittel. June 1956. 20p. diagrs., photos. (NACA TN 3697. Supersedes RM L50F30a)

Comparison of experimental flight-test results with theoretical calculations to determine the effect of wing taper and aspect ratio on the zero-lift drag of wings with thin double-wedge sections at supersonic speeds is presented.

NACA TN 3699

SOME EFFECTS OF JOINT CONDUCTIVITY ON THE TEMPERATURES AND THERMAL STRESSES IN AERODYNAMICALLY HEATED SKIN-STIFFENER COMBINATIONS. George E. Griffith and Georgene H. Miltonberger. June 1956. 62p. diagrs. (NACA TN 3699)

Temperatures and thermal stresses in aerodynamically heated skin-stiffener combinations were calculated with the aid of an electronic differential analyzer. Variations were made in an aerodynamic heat-transfer parameter, a joint conductivity parameter, and the ratio of skin width to skin thickness. The results indicate that decreasing the joint conductivity or increasing the heat-transfer coefficient increases the peak thermal stresses in the skin and may appreciably increase the peak stresses in the stiffener, whereas increasing the ratio of skin width to skin thickness produces some increase in the peak stiffener stresses but a corresponding decrease in the peak skin stresses.

NACA TN 3708

INVESTIGATION AT SUPERSONIC SPEEDS OF THE VARIATION WITH REYNOLDS NUMBER AND MACH NUMBER OF THE TOTAL, BASE, AND SKIN-FRICTION DRAG OF SEVEN BOATTAIL BODIES OF REVOLUTION DESIGNED FOR MINIMUM WAVE DRAG. August F. Bromm, Jr. and Julia M. Goodwin. June 1956. 20p. diagrs., photo. (NACA TN 3708. Supersedes RM L53I29b)

Results are presented from an investigation of the variation with Reynolds number and Mach number of the total, base, and skin-friction drag of seven boattail bodies of revolution designed for minimum wave drag according to the theory of NACA TN 2550. The tests covered a Reynolds number range from approximately 1.0×10^6 to 10.0×10^6 at Mach numbers of 1.62, 1.93, and 2.41, respectively.

NACA TN 3712

BOUNDARY LAYER BEHIND SHOCK OR THIN EXPANSION WAVE MOVING INTO STATIONARY FLUID. Harold Mirels. May 1956. i, 53p. diagrs., tabs. (NACA TN 3712)

The boundary layer behind a shock or thin expansion wave moving into a stationary fluid has been studied. Both laminar and turbulent boundary layers were considered. The wall surface temperature behind the waves was also investigated. Numerical and analytical results are presented for the various boundary-layer parameters of interest. It was found that the wall surface temperature was uniform (as a function of distance behind the wave) for the laminar-boundary-layer case but varies with distance for the turbulent-boundary-layer case.

NACA TN 3713

SELECTION OF OPTIMUM CONFIGURATIONS FOR HEAT EXCHANGER WITH ONE DOMINATING FILM RESISTANCE. E. R. G. Eckert and T. F. Irvine, Jr. June 1956. 48p. diagrs. (NACA TN 3713)

A study is presented for selecting an optimum configuration for a heat exchanger. Compact heat-exchanger configurations with one dominating film resistance are considered. Any one of the parameters (power, weight, volume, or frontal area) can be optimized against any one of the remaining three when the heat exchanger is arranged normal to the approaching primary fluid. When the heat exchanger is inclined at an angle to the upstream direction, any one of the parameters (power, weight, or volume) can be optimized against any one of the remaining two. The projected frontal area of the inclined heat exchanger will equal the frontal area of the exchanger requiring the minimum duct cross-sectional area when arranged normal to the flow.

NACA TN 3715

COMPARISON OF THE EXPERIMENTAL AND THEORETICAL DISTRIBUTIONS OF LIFT ON A SLENDER INCLINED BODY OF REVOLUTION AT $M = 2^1$. Edward W. Perkins and Donald M. Kuehn. May 1956. 39p. diagrs., photos., tabs. (NACA TN 3715. Supersedes RM A53E01)

An investigation of the pressure distribution for a body of revolution, consisting of a 33-1/3 caliber (5.75 fineness ratio) tangent ogival nose and a cylindrical afterbody, has been made for an angle-of-attack range of 0° to 35.5° at a Mach number of 1.98 and a Reynolds number of approximately 0.5×10^6, based on body diameter. Comparisons of the theoretical and experimental pressure distributions are made to show the nature of the effects of both viscosity and cross-flow compressibility. The experimental load distributions are compared with those predicted by the method suggested in NACA RM A9I26 which includes an approximate method for taking into account the effects of viscosity on the lift distribution.

NACA TN 3716

COMPARISON OF EXPERIMENTAL AND THEORETICAL NORMAL-FORCE DISTRIBUTIONS (INCLUDING REYNOLDS NUMBER EFFECTS) ON AN OGIVE-CYLINDER BODY AT MACH NUMBER 1.98. Edward W. Perkins and Leland H. Jorgensen. May 1956. 50p. diagrs., tab. (NACA TN 3716. Supersedes RM A54H23)

Effects of Reynolds number and angle of attack on the pressure distribution and normal-force characteristics of a body of revolution consisting of a fineness ratio 3 ogival nose tangent to a cylindrical afterbody 7 diameters long have been determined. The test Mach number was 1.98 and the angle-of-attack range from 0° to 20°. The Reynolds numbers, based on body diameter, were 0.15×10^{6} and 0.45×10^{6}. The experimental results are compared with theory.

NACA TN 3720

COMPARISON BETWEEN EXPERIMENTAL AND PREDICTED DOWNWASH AT A MACH NUMBER OF 0.25 BEHIND A WING-BODY COMBINATION HAVING A TRIANGULAR WING OF ASPECT RATIO 2.0. Norman E. Sorensen and Edward J. Hopkins. May 1956. 29p. diagrs., photos. (NACA TN 3720)

A comparison is made between experimental and predicted downwash angles and span load distributions for a wing-body combination (maximum diameter to wing span ratio = 0.259) through an angle-of-attack range from 0° to 20°. Positions of the vortex cores indicated by the tuft-grid, the water-tank technique, and a numerical method are compared.

BRITISH REPORTS

Royal Aircraft Establishment (Gt. Brit.)
THE STRENGTH OF TUBES UNDER UNIFORM EXTERNAL PRESSURE. P. C. Cleaver. November 1955. 191p. diagrs., photos., tabs. (RAE Structures 193)

This report traces the development of theoretical solutions to the problem of determining the strength of tubes subjected to uniform external pressure, and describes an extensive series of tests to check the accuracy of the Sturm solution to this problem and the effects of material properties on collapse pressure. A total of 530 tests were made covering ranges of length:diameter from 14.0 to 0.51 and nominal thickness:diameter from 0.0098 to 0.056. The mean collapse pressure of the tests designed to check the accuracy of the Sturm solution corrected for eccentricity effects exceeded the mean theoretical collapse pressure by 2.2 percent, the standard deviation was 7.0 percent, and the distribution approximately Gaussian. It is concluded that this theory may confidently be used to predict the strength of tubes under uniform external pressure applied to the sides only.

Royal Aircraft Establishment (Gt. Brit.)
MECHANICAL PROPERTIES OF Ti 75A SHEET TITANIUM AT ROOM AND ELEVATED TEMPERATURES. D. C. Hayward. November 1955. 19p. diagrs., tabs. (RAE Tech. Note Met. 210)

The mechanical properties in tension and compression were determined on 16 S.W.G. (0.064 inch) sheet at room temperature, 200° C, and 400° C in directions along and transverse to rolling. It was found that at each temperature level, Young's modulus was of a similar order for tension and compression in the same direction but transverse values exceeded longitudinal values. While longitudinal proof-stress values for tension and compression were in most cases exceeded by values in the transverse direction, ultimate tensile stresses were of similar magnitude in both directions. Elongation was greater at 200° C than at either room temperature or 400° C. Stress-strain, tangent-moduli, and secant-moduli curves are given.

EFFECT OF TWO TYPES OF ETCHING PENCIL MARKING ON THE FATIGUE STRENGTH OF ALUMINUM ALLOY DTD. 683. J. T. Ballett. November 1955. 7p. diagrs., tabs. (RAE Tech. Note Met. 232)

Wohler type fatigue tests have been made on specimens of high strength aluminum alloy DTD 683 after treatment by two types of marking pencils, that is, electric etching and pneumatic etching. When compared with plain longitudinally polished specimens, the former type of marking resulted in a drop of fatigue strength at 10^7 cycles of about 70 percent while the latter type resulted in a drop of about 30 percent.

MECHANICAL PROPERTIES OF R. C. 130A SHEET TITANIUM AT ROOM AND ELEVATED TEMPERATURES. D. C. Hayward. November 1955. 20p. diagrs., tabs. (RAE Tech. Note Met. 214)

The mechanical properties in tension and compression were determined on 16 S.W.G. R.C. 130A titanium alloy sheet now designated C. 110M, at room temperature, 200° C, and 400° C in directions along and transverse to rolling. It was found that at each temperature level Young's modulus was about the same for tension and compression in the same direction but transverse values exceeded longitudinal values. Marked differences, up to 25 percent of the maximum stress, between longitudinal and transverse proof stress values were found for both tension and compression; however, at maximum stress these differences were reduced to about 5 percent. Elongation values decreased with increase in temperature over the range considered. Stress-strain, tangent-moduli, and secant-moduli curves are given.

THERMAL SHOCK STRESSES IN A CYLINDER OF RECTANGULAR CROSS SECTION. P. W. H. Howe. February 1956. 27p. diagrs., tabs. (NGTE Memo. M. 263)

The stresses arising when a hot cylinder of rectangular cross section is quenched are calculated. On account of the computing work involved the calculation is made for one set of values only of the length/width ratio of the rectangular cross section, heat-transfer coefficient, and time after quenching starts. For this case the maximum tensile stresses at the corners, at the midpoint of the short side, and at the midpoint of the long side are in the approximate ratio of 3:2:1. The stresses are of the same order as those in a quenched circular cylinder. If the method can be programed for an automatic computing machine, it will be a practical proposition to calculate thermal shock stresses in a turbine blade.

CORROSION AND STRESS CORROSION PROPERTIES OF ALUMINUM-COPPER AND ALUMINUM-COPPER-CADMIUM ALLOYS. C. Braithwaite. November 1955. 9p. tabs. (RAE Tech. Note Met. 219)

Fulmer Research Institute have carried out some work for the Ministry of Supply on the aging characteristics. etc., of aluminium-copper alloys. It was required to investigate the corrosion resistance with and without stress on the most promising of these alloys after heat treatment to obtain the maximum tensile strength. The alloys supplied by the Institute were aluminium/$4\frac{1}{4}$ percent copper and aluminium/$4\frac{1}{4}$ percent copper/0.097 percent cadmium. Both alloys showed remarkable high corrosion resistance under intermittent sea-water spray conditions with and without stress. A safe stress of over the 0.1-percent proof stress was maintained for 18 months. When exposed without load for 18 months neither of the alloys lost any tensile strength.

AN INVESTIGATION INTO THE TRANSMISSION OF DATA OVER A TELEPRINTER LINK. A. Cohen. January 1956. 10p. (RAE Tech. Note TD 2)

The necessity for sending G. W. Trials Data from G. W. T. W., Aberporth to R. A. E. Farnborough for computations on the R. A. E. Digital Computer "DEUCE" has led to an investigation of a system for transmitting the data over a teleprinter link. This method appears to be promising but it is considered necessary to carry out a series of tests on such a teleprinter link. Some 3 months' experience with this test link indicates that, to cope with most eventualities, a system of automatic detection and correction of errors would be necessary. A system is proposed using direct transmission between Hollerith cards. It is shown that the efficiency of this system would be of the order of 90 percent.

Marine Aircraft Experimental Establishment (Gt. Brit.) TOWING TANK TESTS TO DETERMINE THE WATER DRAG TO THE HULL OF A JET PROPELLED FLYING BOAT FIGHTER (SPEC. E. 6/44) AND COMPARISON WITH FULL SCALE MEASUREMENTS. R. V. Gigg, A. G. Kurn, and J. K. Friswell. May 1955; February 1956 (rev.). 41p. diagrs., tab. (MAEE F/Res/263)

The water drag, draught, wetted areas, and mean wetted lengths of a 1/9-scale E. 6/44 flying boat model hull have been measured for all anticipated take-off loads and attitudes over the take-off run. A method of scaling up model drag to make allowances for the differences in skin friction, model and full scale, has been used and the results compared with actual full-scale tests. There is not satisfactory agreement between estimated and measured full-scale results, and the tests do not provide sufficient evidence to determine whether the accurate estimation of full-scale water resistance by the methods used is possible.

Royal Aircraft Establishment (Gt. Brit.) FLUTTER PREDICTION IN PRACTICE. E. G. Boradbent. (To be presented at Structures and Materials Panel, Advisory Group for Aeronautical Research and Development, Washington, D. C., April 1956). February 1956. 32p. diagrs., tabs. (RAE Tech. Note Structures 185)

A brief summary is given of the resources available for flutter prediction, both experimental and theoretical. Specific flutter investigations are described for four separate flutter incidents which have occurred in Great Britain during the past few years. In all four examples good agreement is eventually obtained between the calculations and full-scale experience and it is thought that useful lessons can be learned from the steps which proved necessary to get this agreement. Two of the examples relate to classical flutter, in which compressibility is unimportant, but in the other two examples, although compressibility is important, it would have been wrong to conclude that the incidents were only due to negative aerodynamic damping in one degree of freedom. Conclusions for future guidance are drawn from all the examples, with particular reference to the aerodynamic treatment. The paper concludes with a few points from a more general statistical survey of recent incidents.

Aeroplane and Armament Experimental Establishment (Gt. Brit.) AN ANALYSIS OF THE METEOROLOGICAL CONDITIONS WHICH MAY CAUSE THE MISTING OF AIRCRAFT TRANSPARENCIES. G. C. Abel and K. W. Taylor. March 21, 1956. 9p. diagrs., tabs. (AAEE/Tech/123)

Analysis of meteorological data shows that the atmospheric conditions in U.K. give little direct indication of the chances of aircraft transparencies misting in the tropics. The tropical high altitude temperatures are lower and the low altitude dewpoints higher, especially over the sea, so that even the worst conditions obtainable in U.K. are less likely to cause misting than those that can be experienced almost any day in the tropics by high flying aircraft descending rapidly for a strike or for combat or to land.

Polytechnic Institute of Brooklyn. CALCULATION OF STABILITY OF CONSTANT-PRESSURE BOUNDARY LAYERS ON ISOTHERMAL SURFACES WITH AN INTEGRAL-METHOD MEAN-FLOW SOLUTION. Martin Bloom. September 25, 1953. 68p. diagrs., tabs. (Polytechnic Institute of Brooklyn. PIBAL Rept.179)

The laminar boundary layer with constant pressure, heat transfer through an isothermal surface, unit Prandtl number, a linear temperature-viscosity relation, and constant heat capacity is considered. Velocity profile derivatives obtained by assuming a sixth-degree polynomial profile in the Kármán-Pohlhausen integral method are shown to agree well with those of a mathematically exact solution. Comparative calculations of minimum critical Reynolds numbers for laminar boundary-layer stability, made with both integral-method and more exact mean-flow values, for $M < 2$, are shown to agree reasonably well with each other. The stability theory of Lees and Lin is used for this purpose.

HARMONIC ANALYSIS APPLIED TO VIBRATION TESTS OF NONLINEAR STRUCTURES. (L'analyse harmonique appliquee aux essais de vibration des structures non-lineaires). G. deVries. April 1956. 15p. diagrs. (Trans. from Recherche Aéronautique, no.44, March-April 1955)

The application of harmonic analysis to the measurement of vibration offers unquestionable advantages from both the theoretical and practical viewpoint. It gives an effective means of measuring with precision the natural values of nonlinear systems, but it facilitates equally measurements on practically linear systems. In view of the fact that the mobile elements of the pickups may be very light, the structure is little affected by the measuring apparatus. The absence of electronic means makes the measurement simple, avoids elements variable with time, thus repeated calibrations, and facilitates employment of a great number of pickups.

National Bureau of Standards. STRENGTH AND STRESS DISTRIBUTION TEST OF A SIMPLIFIED LOW ASPECT RATIO SWEPT WING SUBJECTED TO LATERAL POINT LOADS. Stanley Goodman and Stanton B. Russell. July 30, 1954. 30p. diagrs., photos., tabs. (National Bureau of Standards. Rept.3486)

Stress distribution, deformation, and rotation at the root were measured for a tapered, swept, low-aspect-ratio two-cell simplified wing subjected to a sequence of elastic lateral loads at various points. The wing was tested to failure by a lateral point load applied to the main spar. For purposes of comparison, influence coefficients were computed by conventional methods for a nonswept wing having the same bending and torsional stiffness as the swept wing clear of the root and tip sections. In addition comparison was made between the measured influence coefficients and available influence coefficients computed for the wing by a method developed for delta wings.

Harvard University. RESEARCH REPORT, OCTOBER 1952 - MARCH 1953. J. A. Cole. (NACA Lubrication Project). March 1953. 20p. diagrs. (Harvard University)

The construction and limitations of the Harvard rotating cylinder viscometer are examined in the light of experience gained since the resumption of work on the project, and relative to high shear viscometry generally. Results of a series of tests using a mineral oil and of preliminary tests using a polymer-containing oil in the shear rate range 0.001-0.25 million reciprocal sec. are presented in terms of the Hagg thermal effects analysis. The temperature measurements are shown to be in good agreement, but the torque measurements confirm that the present torque-meter is unsatisfactory. An extension of the analysis of thermal conditions to the case of non-Newtonian lubricants is proposed.

Columbia University. ADIABATIC HEATING AND TEMPERATURE-RECOVERY FACTOR OF THE WALLS OF TUBES CARRYING LIQUIDS OF HIGH PRANDTL NUMBER. Charles F. Bonilla, James P. Collins, and Susanta K. Aditya. (Final report). March 15, 1955. 51p. diagrs., tabs. (Columbia University. CU-4-55-NAw-6160-Ch.E)

Oil of Prandtl number ranging from 80 to 600 was pumped at velocities of 20 to 70 ft/sec through a tube of 0.4 in. internal diameter and 100 diameters long, with a rounded inlet nozzle. The adiabatic wall temperature rise was measured, ranging up to 3.8° F. Low or negative recovery factors were obtained at both ends. Streamline flow was obtained at diameter RN up to 12,000. The temperature-recovery factor based on mean stream temperature and velocity increased downstream fairly linearly towards a highest value of 17 to 37, giving indication that it would keep on increasing in a longer tube, possibly towards the theoretical value of twice the Prandtl number. Turbulent flow was achieved in the stream by inserting a rod across the stream and fairly uniform values of the recovery factor, roughly equal to the square root of the Prandtl number, were obtained over at least half of the length of the tube. No clear-cut transition from a laminar to a turbulent boundary layer was noted.

Applied Science Research Laboratory, University of Cincinnati. OXIDATIVE DEGRADATION OF METHYLCYCLOHEXANE AND n-HEPTANE. Donald Swarts. (Final report, September 1, 1954 - August 31, 1955). August 10, 1955. 32p. diagrs., tabs. (Applied Science Research Laboratory, University of Cincinnati)

The present study shows the tendency of methylcyclohexane and n-heptane to form carbonaceous deposits and their relative rates of vapor phase oxidation at various temperatures and hydrocarbon-oxygen compositions. The formation of cokes and resins from these two compounds at both high and low temperatures was observed and the relation between temperature, contact time, hydrocarbon-oxygen composition and residue formation was studied. The rate of hydrocarbon disappearance in excess oxygen was also studied and the quantitative difference in susceptibility to oxidation of methylcyclohexane and n-heptane was measured. The effect of temperature on reaction rate led to the determination of an approximate over-all energy of activation for the oxidations.

Polytechnic Institute of Brooklyn. A NUMERICAL SOLUTION FOR A CIRCULAR CYLINDRICAL SHELL WITH A SINUSOIDAL LOAD ALONG ONE GENERATOR. Nicholas Perrone and F. S. Shaw. April 1954. 30p. diagrs. (Polytechnic Institute of Brooklyn. PIBAL Rept. 250)

A numerical solution is presented for a circular cylinder of uniform thickness and finite length which is stressed by the application of a normal sinusoidal load acting along one generator. The three simultaneous linear displacement equations derived by Donnell are solved. For boundary conditions it is assumed that both ends of the cylinder are clamped. Finite-difference approximations to derivatives are used, and the resulting simultaneous algebraic equations are solved by a relaxation-iteration technique. For the finite-difference representations a rectangular mesh is used, rather than the usual square one. Values and contours of stress components are presented, as well as displacement components, both for membrane and bending.

Guggenheim Aeronautical Laboratory, California Institute of Technology. ON THE ACOUSTIC RADIATION FROM BOUNDARY LAYERS AND JETS. H. W. Liepmann. August 1954. 24p. diagrs. (Guggenheim Aeronautical Laboratory, California Institute of Technology)

A general discussion of aerodynamically created sound is given which is essentially theoretical but arrives at a description of the physical phenomena in such a way as to yield an immediate access to experiments. The problem of aerodynamic noise is defined and two simple mechanical analogues discussed. The general equations of motion of a viscous, compressible fluid are rearranged in a form suitable for a comparison with Lighthill's approach, but instead the concept of induced velocities due to displacement effects is put forward and carried through for noise produced by boundary-layer flow. The same concept is then extended to describe the sound field created by a jet.

PRELIMINARY EVALUATION OF THE AIR AND FUEL SPECIFIC-IMPULSE CHARACTERISTICS OF SEVERAL POTENTIAL RAM-JET FUELS. II - MAGNESIUM AND MAGNESIUM - OCTENE-1 SLURRIES. Benson E. Gammon. May 2, 1951. 15p. diagrs. (NACA RM E51C23)

A preliminary analytical evaluation of the air and fuel specific-impulse characteristics of magnesium and magnesium - octene-1 slurries has been made. Adiabatic constant-pressure combustion temperatures for each fuel at several equivalence ratios were calculated for an initial air temperature of 560° R and a pressure of 2 atmospheres.

NACA RM E52L08

SUMMARY REPORT ON ANALYTICAL EVALUATION OF AIR AND FUEL SPECIFIC-IMPULSE CHARACTERISTICS OF SEVERAL NONHYDROCARBON JET-ENGINE FUELS. Roland Breitwieser, Sanford Gordon and Benson Gammon. February 1953. 58p. diagrs., tab. (NACA RM E52L08)

An analytical evaluation of the air and fuel specific-impulse characteristics of magnesium, magnesium - octene-1 slurries, aluminum, aluminum - octene-1 slurries, boron, boron - octene-1 slurries, carbon, hydrogen, α-methylnaphthalene, diborane, and pentaborane, is presented herein. Adiabatic constant pressure combustion temperature, air specific impulse, fuel specific impulse, and equilibrium composition data are given for each fuel over a range of equivalence ratios. Data for octene-1, considered representative of aviation gasoline performance, are presented for comparison. Magnesium, magnesium - octene-1 slurries, aluminum, aluminum - octene-1 slurries, boron - octene-1 slurries, pentaborane, diborane, and hydrogen, permit the attainment of air-specific-impulse values beyond the octene-1 limit. At any fixed air specific impulse below 135 seconds, the fuel-weight specific impulses of hydrogen, diborane, pentaborane, boron, boron - octene-1 slurries, are superior to octene-1. The fuel-volume specific impulses of boron, aluminum, carbon, boron - octene-1 slurries, magnesium, pentaborane, α-methylnaphthalene, and magnesium - octene-1 slurries, are superior to octene-1.

NACA RM A9F14

AERODYNAMIC STUDY OF A WING-FUSELAGE COMBINATION EMPLOYING A WING SWEPT BACK 63°. - AERODYNAMIC CHARACTERISTICS IN SIDESLIP OF A LARGE-SCALE MODEL HAVING A 63° SWEPT-BACK VERTICAL TAIL. Gerald M. McCormack. October 7, 1949. 26p. diagrs., photos. (NACA RM A9F14)

Aerodynamic characteristics in sideslip are presented for a wing-fuselage combination employing a wing with the leading edge swept back 63° with and without a vertical tail having the leading edge swept back 63°. Included also are the rudder effectiveness and the rudder hinge-moment characteristics. The experimental results are compared with values predicted theoretically in order to provide a basis for estimating the effects of geometric changes of the vertical tail.

NACA RM A51F15

SOME LOW-SPEED CHARACTERISTICS OF AN AIR-INDUCTION SYSTEM HAVING SCOOP-TYPE INLETS WITH PROVISIONS FOR BOUNDARY-LAYER CONTROL. Earl C. Watson. August 1951. 42p. diagrs., photos., tab. (NACA RM A51F15)

Results are presented of an experimental investigation at subsonic speeds of the main and boundary-layer control air-induction systems designed for a supersonic airplane. A lip profile for the main scoop was developed which provided unseparated external flow for mass-flow ratios down to 0.75 for a wide range of angle of attack, and which improved the pressure recovery in the main duct. The effects of angle of attack, angle of sideslip, and of boundary-layer removal on the pressure recovery in the main and boundary-layer-control ducts are shown for a wide range of mass-flow ratios.

NACA RM A52F16

EFFECT OF CAMBER AND TWIST ON THE STABILITY CHARACTERISTICS OF MODELS HAVING A 45° SWEPT WING AS DETERMINED BY THE FREE-FALL METHOD AT TRANSONIC SPEEDS. Maurice D. White. August 1952. 35p. diagrs., photos., tab. (NACA RM A52F16)

Measurements were made in free fall at transonic speeds of the dynamic stability characteristics of three models. Two of the models had 45° swept wings of aspect ratio 6 and 45° swept tail surfaces, and differed from each other only in that the wing of one of the models was plane and the wing of the other was cambered and twisted. The third model had the same fuselage-tail arrangement as the others, but had no wing. Static and dynamic longitudinal stability characteristics are presented for Mach numbers ranging from 0.84 to 1.16, and static directional-stability characteristics for Mach numbers from 0.60 to 1.13.

NACA RM A53F03

THE LATERAL CONTROL CHARACTERISTICS OF CONSTANT-PERCENT-CHORD TRAILING-EDGE ELEVONS ON A POINTED WING OF ASPECT RATIO 2 AT MACH NUMBERS UP TO 0.95. Verlin D. Reed and Donald W. Smith. August 1953. 105p. diagrs., photo., tabs. (NACA RM A53F03)

Results of tests made of a wing-body combination to determine the lateral control characteristics of constant-percent-chord trailing-edge elevons on a pointed wing with an aspect ratio of 2 and the effectiveness of tabs in reducing elevon hinge moments are presented. The data were obtained for a range of Mach numbers from 0.24 to 0.95 at a constant Reynolds number of 3.0 million and for Reynolds numbers up to 15.0 million at a constant Mach number of 0.24.

NACA RM A53F23

THE EFFECTS OF FENCES ON THE HIGH-SPEED LONGITUDINAL STABILITY OF A SWEPT-WING AIRPLANE. Richard S. Bray. August 1953. 37p. diagrs., photos., tabs. (NACA RM A53F23)

A swept-wing airplane was tested with a series of fence configurations to determine their effects on the longitudinal instability, or pitch-up, noted at Mach numbers between 0.80 and 0.95. Several fence installations significantly delayed the pitch-up to higher lift coefficients at Mach numbers near 0.9.

NACA RM E8F15

PRELIMINARY INVESTIGATION OF EFFECTS OF COMBUSTION IN RAM JET ON PERFORMANCE OF SUPERSONIC DIFFUSERS. I - SHOCK DIFFUSER WITH TRIPLE-SHOCK PROJECTING CONE. J. F. Connors and A. H. Schroeder. September 15, 1948. 18p. diagrs. (NACA RM E8F15)

The effect of combustion on the total-pressure recovery and the Mach number distribution at the diffuser outlet has been determined with a 3.6-inch-diameter ram jet at a Mach number of 1.92. Normal-shock oscillation, initiated by pressure pulsations from the combustion process, causes a rapid decrease in peak total-pressure recovery with increasing outlet area and increasing fuel flows. The cold steady-flow peak total-pressure recovery was not attainable with combustion.

NACA RM E8F28

PERFORMANCE INVESTIGATION OF CAN-TYPE COMBUSTOR. II - WATER INJECTION AT VARIOUS STATIONS IN COMBUSTOR. William P. Cook and Eugene V. Zettle. September 30, 1948. 27p. diagrs. (NACA RM E8F28)

For water introduced at one station ahead of combustor and three stations in can-type combustor of 4000-pound-thrust axial-flow turbojet engine operating at various simulated altitudes from 15,000 to 45,000 feet, the effect on exhaust-gas temperature distribution, the location in the combustor at which the maximum quantity of water can be injected, and the maximum quantities of water that can be injected are determined. The maximum quantity of water was injected in approximately the center of the combustion chamber and the total liquid-air ratio was approximately 0.07.

NACA RM E8G16

PRELIMINARY INVESTIGATION OF EFFECTS OF COMBUSTION IN RAM JET ON PERFORMANCE OF SUPERSONIC DIFFUSERS. II - PERFORATED SUPERSONIC INLET. Albert H. Schroeder and James F. Connors. October 4, 1948. 14p. diagrs. (NACA RM E8G16)

An investigation was conducted on a 3.6-inch-diameter ram jet with a variable-outlet nozzle at a Mach number of 1.92 to determine the effect of an actual combustion process on the performance of a perforated diffuser. Peak total-pressure recovery decreased with increased outlet area and fuel flow. The theory of normal-shock oscillation initiated by pressure pulsations from the combustion process is believed to be an explanation for this decrease. The combustion process did not alter the Mach number distribution at the combustion-chamber inlet as compared with the distribution without combustion on the basis of equal pressure recovery.

NACA RM E8J18

PRELIMINARY INVESTIGATION OF EFFECTS OF COMBUSTION IN RAM JET ON PERFORMANCE OF SUPERSONIC DIFFUSERS. III - NORMAL-SHOCK DIFFUSER. Albert H. Schroeder and James F. Connors. December 22, 1948. 15p. diagrs. (NACA RM E8J18)

Effects of combustion on performance of a basic normal-shock diffuser were experimentally determined at a Mach number of 1.92 on a 3.60-inch-diameter ram jet. Total-pressure recovery was evaluated as a function of outlet-inlet area ratio and fuel flow. As a result of unsteady flow conditions associated with normal-shock oscillations, a rapid decrease in peak total-pressure recovery was obtained with increasing outlet-inlet area ratio. Modifications to the combustion chamber produced no noticeable change in this phenomenon. A marked improvement in total-pressure recovery was obtained, however, when a powdered magnesium flare was used as source of smooth combustion.

NACA RM E50D20

STARTING OF ROCKET ENGINE AT CONDITIONS OF SIMULATED ALTITUDE USING CRUDE MONOETHYLANILINE AND OTHER FUELS WITH MIXED ACID. Dezso J. Ladanyi, John L. Sloop, Jack C. Humphrey, and Gerald Morrell. July 19, 1950. 64p. diagrs., photos., tabs. (NACA RM E50D20)

Experiments were conducted at sea level and pressure altitude of about 55,000 feet at various temperatures to determine starting characteristics of a commercial rocket engine using crude monoethylaniline and other fuels with mixed acid. With crude monoethylaniline, ignition difficulties were encountered at temperatures below about 20° F. With mixed butyl mercaptans, water-white turpentine, and α-pinene, no starting difficulties were experienced at temperatures as low as -74° F. Turpentine and α-pinene, however, sometimes left deposits on the injector face. With blends containing furfuryl alcohol and with other blends, difficulties were experienced either from appreciable deposits or from starting.

NACA RM E50H16

LOW-TEMPERATURE IGNITION-DELAY CHARACTERISTICS OF SEVERAL ROCKET FUELS WITH MIXED ACID IN MODIFIED OPEN-CUP-TYPE APPARATUS. Riley O. Miller. October 17, 1950. 23p. diagrs., photos., tabs. (NACA RM E50H16)

Summaries of low-temperature self-ignition data of various rocket fuels with mixed acid (nitric plus sulfuric) are presented. Several fuels are shown to have shorter ignition-delay intervals and less variation in delay intervals at moderate and subzero temperatures than crude N-ethylaniline (monoethylaniline), a rocket fuel in current use.

NACA RM E51F12

TWO-DIMENSIONAL CASCADE INVESTIGATION OF THE MAXIMUM EXIT TANGENTIAL VELOCITY COMPONENT AND OTHER FLOW CONDITIONS AT THE EXIT OF SEVERAL TURBINE BLADE DESIGNS AT SUPERCRITICAL PRESSURE RATIOS. Cavour H. Hauser and Henry W. Plohr. August 1951. 34p. diagrs., photos. (NACA RM E51F12)

The nature of the flow at the exit of a row of turbine blades for the range of conditions represented by four different blade configurations was evaluated by the conservation-of-momentum principle using static-pressure surveys and by analysis of schlieren photographs of the flow. It was found that for blades of the type investigated, the maximum exit tangential-velocity component is a function of the blade geometry only and can be accurately predicted by the method of characteristics. A maximum value of exit velocity coefficient is obtained at a pressure ratio immediately below that required for maximum blade loading followed by a sharp drop after maximum blade loading occurs.

NACA RM E51J01

IGNITION DELAY EXPERIMENTS WITH SMALL-SCALE ROCKET ENGINE AT SIMULATED ALTITUDE CONDITIONS USING VARIOUS FUELS WITH NITRIC ACID OXIDANTS. Dezso J. Ladanyi. January 1952. 44p. diagrs., photos., tabs. (NACA RM E51J01)

Ignition delay determinations of several fuels with nitric acid oxidants were made at simulated altitude conditions utilizing a small-scale rocket engine of approximately 50 pounds thrust. Included in the fuels were aniline, hydrazine hydrate, furfuryl alcohol, furfuryl mercaptan, turpentine, and mixtures of triethylamine with mixed xylidines and diallylaniline. Red fuming, white fuming, and anhydrous nitric acids were used with and without additives. A diallylaniline - triethylamine mixture and a red fuming nitric acid analyzing 3.5 percent water and 16 percent NO_2 by weight was found to have a wide temperature-pressure ignition range, yielding average delays from 13 milliseconds at 110° F to 55 milliseconds at -95° F regardless of the initial ambient pressure that ranged from sea-level pressure to a pressure altitude of 94,000 feet.

NACA RM E52C21

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. XI - INTERNAL-STRUT-SUPPORTED ROTOR BLADE. Reeves P. Cochran, Francis S. Stepka, and Morton H. Krasner. June 1952. 45p. diagrs., photos., tabs. (NACA RM E52C21)

The cooling effectiveness and cooling-air pressure losses of an air-cooled internal-strut-supported blade were investigated in a modified production turbojet engine over a range of engine speeds and coolant-to-gas weight-flow ratios per blade. Comparisons of the results of this investigation with similar investigations of shell-supported blades showed that the cooling effectiveness and stress-ratio factor are higher for the strut-supported blade than for the shell-supported blades, and that the cooling-air pressure losses for the strut-supported blade are within the range of pressure losses for the shell-supported blades. On the basis of these comparisons, the strut-supported blade indicated promise of operating at higher turbine-inlet temperatures or at lower coolant-to-gas weight-flow ratios per blade than shell-supported blades. Comparison of experimental results with analytically predicted results indicated that the analytical method of predicting temperatures in a strut-supported blade was sufficiently accurate for design purposes.

NACA RM E52F24

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. XII - COOLING EFFECTIVENESS OF A BLADE WITH AN INSERT AND WITH FINS MADE OF A CONTINUOUS CORRUGATED SHEET. Edward R. Bartoo and John L. Clure. August 1952. 33p. diagrs., photos. (NACA RM E52F24)

An investigation was conducted in a modified turbojet engine to determine the cooling effectiveness of an air-cooled corrugated-fin blade. The results of this investigation are shown and comparisons are made with two of the most promising shell-supported blade types previously investigated at NACA and also with an air-cooled blade in which the shell was supported by an internal strut. Calculations indicate that a corrugated fin blade made of Timken 17-22A(S) nonstrategic steel can operate safely at rated engine conditions at cooling-air-to-combustion-gas flow ratios of 0.01 or less with cooling-air inlet temperatures up to 450° F.

NACA RM E52J01

SOME FUNDAMENTAL ASPECTS OF NITRIC ACID OXIDANTS FOR ROCKET APPLICATIONS. Dezso J. Ladanyi, Riley O. Miller, Wolf Karo, and Charles E. Feiler. January 1953. ii, 95p. diagrs., tabs. (NACA RM E52J01)

The literature pertaining to the preparation, physical properties, corrosiveness, thermal stability, constitution, and analysis of various nitric acids is reviewed primarily with respect to their use as rocket oxidants. Conflicting data are evaluated and recommendations for additional experimental work are indicated. Reactions of nitric acid which could occur during the starting and steady-stage phases of rocket operation are discussed and probable mechanisms are selected on the basis of reported thermal and kinetic data.

NACA RM E52J15

PRELIMINARY INVESTIGATION OF COMPRESSOR BLADE VIBRATION EXCITED BY ROTATING STALL. Merle C. Huppert, Donald F. Johnsen, and Eleanor L. Costilow. December 1952. 27p. diagrs., photos. (NACA RM E52J15)

A preliminary investigation of compressor blade vibration excited by rotating stall was conducted on a single-stage axial-flow compressor with a hub-tip ratio of 0.5. Resonant bending vibrations were excited in the aluminum stator blades by rotating stall.

NACA RM E52K19

ORTHOTOLUIDINE AND TRIETHYLAMINE IN ROCKET ENGINE APPLICATIONS. Dezso J. Ladanyi. January 1953. 24p. diagrs., tabs. (NACA RM E52K19)

The literature pertaining to the use of orthotoluidine and triethylamine in rocket propellant combinations was surveyed and summarized with particular emphasis on ignition delay investigations and fuel mixture applications. In addition, experimental ignition delay determinations of two orthotoluidine-triethylamine mixtures (1:1 and 3:7 by volume) and a low-freezing-point red fuming nitric acid were conducted at simulated altitude conditions utilizing a small-scale rocket engine of approximately 50 pounds thrust. The delays varied almost linearly from about 12 milliseconds at 120° F to about 28 milliseconds at -70° F for both propellant combinations. At -95° F, the ignition delays for the 1:1 and 3:7 fuel blends were about 101 and 29 milliseconds, respectively. Experiments at pressure altitudes of about 90,000 feet at the two temperature extremes indicated no significant effect of low initial ambient pressure on ignition delay.

NACA RM E53D03

COMPARISON OF IGNITION DELAYS OF SEVERAL PROPELLANT COMBINATIONS OBTAINED WITH MODIFIED OPEN-CUP AND SMALL-SCALE ROCKET ENGINE APPARATUS. Dezso J. Ladanyi and Riley O. Miller. June 1953. 20p. diagrs., photos., tabs. (NACA RM E53D03)

Ignition delays of several propellant combinations obtained with a modified open-cup apparatus and with a small-scale rocket engine of approximately 50-pounds thrust were compared to study any correlations that might exist between the two methods of ignition-delay determination. The comparison showed that the results were generally similar for the same propellant combinations at the same operating conditions as long as the propellant viscosities were low enough to produce no significant effect on ignition delay.

NACA RM E53G14

ANALYTICAL EVALUATION OF EFFECT OF EQUIVALENCE RATIO, INLET-AIR TEMPERATURE, AND COMBUSTION PRESSURE ON PERFORMANCE OF SEVERAL POSSIBLE RAM-JET FUELS. Leonard K. Tower and Benson E. Gammon. September 1953. 59p. diagrs., tabs. (NACA RM E53G14)

The results of an analytical investigation of the theoretical air specific impulse performance and adiabatic combustion temperatures of several possible ram-jet fuels over a range of equivalence ratios, inlet-air temperatures, and combustion pressures, are presented herein. The fuels include octene-1, 50-percent-magnesium slurry, boron, pentaborane, diborane, hydrogen, carbon, and aluminum. Thermal effects from high combustion temperatures were found to affect considerably the combustion performance of all the fuels. An increase in combustion pressure was beneficial to air specific impulse at high combustion temperatures. The use of these theoretical data in engine operation and in the evaluation of experimental data is described.

NACA RM E53G31

EFFECTS OF NITROGEN TETROXIDE AND WATER CONCENTRATION ON FREEZING POINT AND IGNITION DELAY OF FUMING NITRIC ACID. Riley O. Miller. September 1953. 32p. diagrs., tabs. (NACA RM E53G31)

The interrelated effects of water from 0 to 10 percent and nitrogen tetroxide from 0 to 25 percent by weight in fuming nitric acid were investigated with respect to the freezing points of the acids and the ignition delays of the acids with several fuels. An equilibrium freezing-point surface for the acids in the composition range studied is presented. A minimum freezing point of -88.5° F occurs in the region of approximately 5 percent water and 17 percent nitrogen tetroxide and a binary eutectic line extends from this region to nearly anhydrous acids containing 25 to 26 percent nitrogen tetroxide (-82.5° F). The ignition delays of fuel blends of 30 percent o-toluidine, 50 percent allylamine, and 50 percent ethylenimine, respectively, in triethylamine were determined at 70° and -40° F. In general, acids containing small amounts of water and large amounts of nitrogen tetroxide give shorter delays than acids containing large amounts of water and small amounts of nitrogen tetroxide; this effect is more pronounced at low temperature. An acid composition region giving low freezing points falls within the region of short ignition delay.

NACA RM E53I09

EXPERIMENTAL AND THEORETICAL INVESTIGATION OF ROTATING-STALL CHARACTERISTICS OF SINGLE-STAGE AXIAL-FLOW COMPRESSOR WITH HUB-TIP RATIO OF 0.76. Robert W. Graham and Vasily D. Prian. November 1953. 34p. diagrs., photos., tab. (NACA RM E53I09)

The rotating-stall characteristics of a single-stage compressor with a hub-tip ratio of 0.76 and a symmetrical velocity diagram were investigated over a wide range of weight flow and speed. The number and speed of total- and partial-span rotating stalls were experimentally determined. The compressor performance map reveals no effect of compressor speed on the magnitude of the flow coefficients marking the boundaries of the rotating-stall regions; however, hysteresis effects were apparent in shifting the rotating-stall regions during increasing and decreasing weight-flow operations. A theory on rotating stall was applied to the data obtained from this and other similar compressors in an attempt to evaluate some of the factors that affect the mechanism of rotating stall. A correlation was obtained between a stall-propagation-rate parameter and the aerodynamic phase angle of the rotor blades.

NACA RM E54F23a

EXPERIMENTAL INVESTIGATION OF AIR-COOLED TURBINE BLADES IN TURBOJET ENGINE. XIV - ENDURANCE EVALUATION OF SHELL-SUPPORTED TURBINE ROTOR BLADES MADE OF TIMKEN 17-22A(S) STEEL. Francis S. Stepka, H. Robert Bear, and John L. Clure. September 1954. 29p. diagrs., photos., tabs. (NACA RM E54F23a)

These blades with mild-steel tube inserts were investigated over a range of cooling-air to combustion-gas flow ratios in a modified turbojet engine. Modifications of the original construction and various heat treatments effected a satisfactory durability. At a coolant-flow ratio of 0.027, for example, two blades were in good condition after 350-hour operation. A design criterion for the blades, the stress-ratio factor (av. allowable stress-rupture strength to av. centrifugal stress), is presented, the mean value of which was about 2.3 over the range of coolant-flow ratio from 0.015 to 0.027.

NACA RM L50F06

PRESSURE MEASUREMENTS ON A SHARPLY CONVERGING FUSELAGE AFTERBODY WITH JET ON AND OFF AT MACH NUMBERS FROM 0.8 TO 1.6. William E. Stoney, Jr., and Ellis Katz. August 10, 1950. 18p. diagrs., photos. (NACA RM L50F06)

Pressure measurements were made in free flight on a sharply converging fuselage afterbody with jet on and off at Mach numbers from 0.8 to 1.6. The negative pressures over the afterbody were indicated to be very high although less than predicted by linearized theory. This difference may account for the discrepancy in experimental and theoretical drag shown by previous flight tests of this type of body.

NACA RM L50F08

EFFECTS OF VARYING THE SIZE AND LOCATION OF TRAILING-EDGE FLAP-TYPE CONTROLS ON THE AERODYNAMIC CHARACTERISTICS OF AN UNSWEPT WING AT A MACH NUMBER OF 1.9. Meade H. Mitchell, Jr. August 16, 1950. 33p. diagrs., photo., tab. (NACA RM L50F08)

Plain flaps covering a range of flap chords, spans, and spanwise locations were tested on an unswept, semispan wing that had an aspect ratio of 2.5, a taper ratio of 0.625, and 6-percent-thick modified double-wedge airfoil sections. The tests were made with the wing in the presence of a half-fuselage in the Langley 9- by 12-inch supersonic blowdown tunnel at a Mach number of 1.9 and a Reynolds number of 2.3×10^6 and covered a small angle-of-attack range. Experimental flap characteristics are compared with the characteristics calculated by linearized theory.

NACA RM L50H21

FLIGHT INVESTIGATION OF A ROLL-STABILIZED MISSILE CONFIGURATION AT VARYING ANGLES OF ATTACK AT MACH NUMBERS BETWEEN 0.8 AND 1.79. Jacob Zarovsky and Robert A. Gardiner. March 6, 1951. 38p. diagrs., photos., tab. (NACA RM L50H21)

A missile research model was flown at supersonic speed to determine the quality of automatic roll stabilization at varying angles of attack. Aerodynamic rolling and pitching derivatives were determined from the flight record. It was concluded that the combination of the gyro-actuated automatic pilot with wing-tip ailerons provided adequate roll stabilization under conditions encountered in flight.

NACA RM L51F07

TRANSONIC-WING INVESTIGATION IN THE LANGLEY 8-FOOT HIGH-SPEED TUNNEL AT HIGH SUBSONIC MACH NUMBERS AND AT A MACH NUMBER OF 1.2. ANALYSIS OF PRESSURE DISTRIBUTION OF WING-FUSELAGE CONFIGURATION HAVING A WING OF 45° SWEEPBACK, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTION. Donald L. Loving and Bruce B. Estabrooks. September 1951. 132p. diagrs., photos. (NACA RM L51F07)

An analysis is presented of the detailed pressure distributions measured in the Langley 8-foot high-speed tunnel on a fuselage and wing-fuselage combination employing a wing with 45° sweepback of the 0.25-chord line, aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil section. Pressure measurements were obtained on the wing-fuselage combination at angles of attack from -2° to 14° at Mach numbers from 0.60 to 0.96 and at angles of attack from -2° to 6° at a Mach number of 1.2. Fuselage pressure measurements were obtained at angles of attack from 0° to 14° for all Mach numbers investigated. Flow phenomena are discussed and the problems of wing-fuselage interference are explored.

NACA RM L52F02a

TRANSONIC FLIGHT TESTS TO DETERMINE THE EFFECT OF THICKNESS RATIO AND PLAN-FORM MODIFICATION ON THE ZERO-LIFT DRAG OF A 45° SWEPTBACK WING. William B. Pepper, Jr., and Sherwood Hoffman. August 1952. 24p. diagrs., photos., tabs. (NACA RM L52F02a)

Rocket-powered models were flown at transonic speeds to determine the effect of wing-thickness-ratio variation on the zero-lift drag coefficient of a 45° sweptback wing of aspect ratio 6 and taper ratio 0.6 and on a composite plan-form wing of aspect ratio 4 with considerable taper. The wing-plus-interference pressure drag coefficient for both plan forms was found to vary approximately linearly with the square of the mean thickness ratio at low supersonic speeds.

NACA RM L52F05

LONGITUDINAL STABILITY, TRIM, AND DRAG CHARACTERISTICS OF A ROCKET-PROPELLED MODEL OF AN AIRPLANE CONFIGURATION HAVING A 45° SWEPTBACK WING AND AN UNSWEPT HORIZONTAL TAIL. James H. Parks and Alan B. Kehlet. August 1952. 29p. diagrs., photos., tab. (NACA RM L52F05)

The longitudinal aerodynamic characteristics of a swept-wing rocket-propelled model of an airplane configuration with a fixed horizontal tail were investigated in free flight at Mach numbers from 0.63 to 1.16. Static and dynamic longitudinal-stability data were obtained by a pulse rocket technique and continuous values of trim lift and drag at trim lift were determined.

NACA RM L52F06

LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A CANARD MISSILE CONFIGURATION FOR MACH NUMBERS FROM 1.1 TO 1.93 AS DETERMINED FROM FREE-FLIGHT AND WIND-TUNNEL INVESTIGATIONS. Howard J. Curfman, Jr., and Carl E. Grigsby. August 1952. 28p. diagrs., tab. (NACA RM L52F06)

A comparison has been made of the static longitudinal stability and control characteristics of a canard missile configuration as determined from supersonic free-flight and wind-tunnel tests to a Mach number of 1.93. Correlation was shown for the lift and moment curve slopes, including the nonlinear variations with angle of attack. Frequency-response curves are presented using derivatives obtained from both flight and wind-tunnel tests.

NACA RM L52F09

PRELIMINARY FREE-FLIGHT INVESTIGATION OF THE EFFECTS OF RIVETS AND LAP JOINTS ON THE DRAG OF BODIES AT ZERO LIFT AT SUPERSONIC MACH NUMBERS TO 2.1. Russell N. Hopko. August 1952. 12p. diagrs., photos., tab. (NACA RM L52F09)

The effects of protruding rivets and lap joints on the drag of bodies at zero lift at supersonic Mach numbers to 2.1 were measured in free flight. Brazier head rivets caused the smallest drag increases while forward-facing lap joints caused the largest drag increases.

NACA RM L52F10

PRELIMINARY DATA AT A MACH NUMBER OF 2.40 OF THE CHARACTERISTICS OF FLAP-TYPE CONTROLS EQUIPPED WITH PLAIN OVERHANG BALANCES. James N. Mueller and K. R. Czarnecki. September 1952. 43p. diagrs., photos. (NACA RM L52F10)

The preliminary results of an investigation to determine the aerodynamic characteristics of plain overhang balances on flap-type controls are presented for a Mach number of 2.40 and a Reynolds number of 0.78×10^6. The values of section hinge moment, pitching moment, normal force, and chord force as a function of flap deflection and angle of attack for a basic wing equipped with flaps of 38-, 60-, and 82-percent balance are included. Some effects of gap size are shown for the flap of least balance.

NACA RM L52F30

FREE-FLIGHT TESTS AT MACH NUMBERS FROM 0.8 TO 1.4 TO DETERMINE THE EFFECT ON ZERO-LIFT DRAG OF INCREASING THE LEADING-EDGE BLUNTNESS OF A 45° SWEPTBACK WING HAVING AN NACA 65A009 AIRFOIL. William B. Pepper, Jr. August 1952. 15p. diagrs., photos., tabs. (NACA RM L52F30)

The effect on zero-lift drag of increasing the leading-edge bluntness of a 45° sweptback wing of aspect ratio 6 having NACA 65A009 airfoil sections has been measured by rocket-propelled free-flight models for a range of Mach numbers from 0.8 to 1.4. An increase in the wing leading-edge bluntness increased the wing-plus-interference drag coefficient approximately 0.002 through a range of Mach numbers from 0.8 to 1.2, and 0.006 at a Mach number of 1.37.

NACA RM L53F09

WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF GEOMETRIC DIHEDRAL ON THE AERODYNAMIC CHARACTERISTICS IN PITCH AND SIDESLIP OF AN UNSWEPT- AND A 45° SWEPTBACK-WING-FUSELAGE COMBINATION AT HIGH SUBSONIC SPEEDS. Richard E. Kuhn and John W. Draper. July 1953. 41p. diagrs., photos. (NACA RM L53F09)

This report presents the effect of geometric dihedral on the aerodynamic characteristics in pitch and sideslip on two wing-fuselage configurations. The wings had sweepback angles of 3.6° and 45° at the quarter-chord line, aspect ratio of 4, taper ratio of 0.6, and an NACA 65A006 airfoil section parallel to the fuselage center line. The tests covered a Mach number range from 0.40 to 0.95 (Reynolds numbers from 1.8 to 3.0×10^6), an angle-of-attack range from -3° to 24°, sideslip angles from -3° to 12°, and dihedral angles of -10°, -5°, 5°, and 10°.

NACA RM L53F10

A PRELIMINARY INVESTIGATION OF THE POWER REQUIREMENTS OF SLOTTED TEST SECTIONS. John S. Dennard. July 1953. 32p. diagrs. (NACA RM L53F10)

A series of preliminary tests has been conducted to examine the nature of bleed-air power losses of slotted tunnels and to examine methods of reducing these losses. The use of a sharpened slot cutoff at the downstream end of the slot together with an auxiliary pump for bleed-air removal provided operation for Mach numbers less than 1.2 at power parameters

less than those for any other configuration tested. The installation in the open-ejector-type test section of a small volume bleed-flow passage together with a slot diffuser in place of the original plenum did not radically change the longitudinal Mach number distribution of the basic slotted test section and resulted in operation at Mach numbers above 1.2 at power parameters less than those for any other configuration tested.

NACA RM L53F11

SLOTTED-BOUNDARY INTERFERENCE EFFECTS ON WEDGE AIRFOILS AT LOW SUPERSONIC MACH NUMBERS. William J. Nelson and Allen R. Vick. July 1953. 27p. diagrs., photos. (NACA RM L53F11)

An investigation of shock reflection and boundary interference effects at Mach numbers between 1.0 and 1.5 has been conducted in a two-dimensional jet with flat, slotted boundaries above and below the test models. The 1/16-inch slots were separated by 1/4-inch rectangular bars of 1/2-inch depth providing a free area equal to 20 percent of the slotted-wall area. Three simple wedges with apex angles of 4°, 6°, and 10° were tested at 0° angle of attack over a range of model to wall spacings from 3/8 to 1-7/8 times the model chord. Surface pressure variations with Mach number are compared with interference-free data and shock theory to determine the magnitude of the slotted wall interference.

NACA RM L53F17a

REVIEW AND INVESTIGATION OF UNSATISFACTORY CONTROL CHARACTERISTICS INVOLVING INSTABILITY OF PILOT-AIRPLANE COMBINATION AND METHODS FOR PREDICTING THESE DIFFICULTIES FROM GROUND TESTS. William H. Phillips, B. Porter Brown, and James T. Matthews, Jr. August 1953. 57p. diagrs., photos. (NACA RM L53F17a)

A number of examples are presented of control difficulties which appear to result from a tendency for dynamic instability of the combination of the pilot, control system, and airplane. These difficulties have occurred in both conventional and power control systems. Tests of a bomber and a fighter airplane equipped with hydraulic-power controls have been made to study this problem. The effect of friction in the control valves of the power control systems is discussed. An analytical study of the problem and a method of detecting such control difficulties by means of ground simulator tests are presented.

NACA RM L53F24

EFFECT OF REDUCTION IN THICKNESS FROM 6 TO 2 PERCENT AND REMOVAL OF THE POINTED TIPS ON THE SUBSONIC STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A 60° TRIANGULAR WING IN COMBINATION WITH A FUSELAGE. William E. Palmer. August 1953. 44p. diagrs., photo., tab. (NACA RM L53F24)

Lift, drag, and pitching-moment data are presented to show the effect of reducing the thickness ratio of a 60° triangular wing from 6 percent to 2 percent at Mach numbers from 0.15 to 0.40 and Reynolds numbers from 0.9×10^6 to 9×10^6. Presented, in addition, are the effects of removing the outer 24.9 percent of the span of the 6-percent-thick wing through a range of Mach number from 0.40 to 0.85 at Reynolds numbers of 3×10^6 to 6×10^6. Angles of attack range from -4° to 36° for all tests except where limited by tunnel choke.

NACA RM L53H18

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 0.09-SCALE MODEL OF THE BELL X-5 RESEARCH AIRPLANE AND COMPARISON WITH FLIGHT. Ralph P. Bielat and George S. Campbell. October 1953. 65p. diagrs., photo. (NACA RM L53H18)

An investigation was conducted in the Langley 8-foot transonic tunnel to determine the longitudinal stability and control characteristics of a 0.09-scale model of the Bell X-5 research airplane. Tests were made for the wing swept back 60°. Lift, drag, pitching-moment, elevator hinge-moment, and pressure-distribution results are presented at Mach numbers varying from 0.60 to 1.10 and Reynolds numbers varying from 2.86×10^6 to 3.56×10^6 based on the mean aerodynamic chord. The wind-tunnel results and dynamic-response calculations based on wind-tunnel data are compared with flight data.

NACA RM L54F23

COMPARISON BETWEEN THEORETICAL AND EXPERIMENTAL RATES OF ROLL OF TWO MODELS WITH FLEXIBLE RECTANGULAR WINGS AT SUPERSONIC SPEEDS. John M. Hedgepeth and Robert J. Kell. August 1954. 21p. diagrs., photo., tabs. (NACA RM L54F23)

A comparison is presented between the experimentally measured and theoretically calculated (by the method of NACA TN 3067) rates of roll of two rocket-propelled models with flexible rectangular wings.

NACA RM L54F24

STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A COMPOSITE-PLAN-FORM WING MODEL INCLUDING SOME COMPARISONS WITH A 45° SWEPTBACK WING AT TRANSONIC SPEEDS. Walter D. Wolhart. August 1954. 36p. diagrs., photo., tabs. (NACA RM L54F24)

Results are presented of an investigation of the low-speed static longitudinal stability characteristics of a composite-plan-form wing tested as a wing-fuselage combination and as a complete model. The Mach number for these tests was 0.16 corresponding to a Reynolds number of 1.98×10^6. Also included are the wing-alone transonic-speed characteristics obtained from tests of small-scale semispan models of the composite-plan-form wing and the conventional sweptback wing from which the composite-plan-form wing was derived. The Mach number range of these tests was 0.70 to 1.09 corresponding to a Reynolds number range of 1.07×10^6 to 1.25×10^6 based on the mean aerodynamic chord of the composite-plan-form wing.

NACA RM L54F29a

SOME EFFECTS OF EXTERNAL WING TIP STORES ON THE ROLLING EFFECTIVENESS AND DRAG OF PLAIN AND HALF-DELTA TIP AILERONS ON A 4-PERCENT-THICK, TAPERED, UNSWEPT WING. Roland D. English. August 1954. 14p. diagrs., photos., tab. (NACA RM L54F29a)

An investigation has been made of some effects of external wing tip stores on the rolling effectiveness and drag of plain and half-delta tip ailerons on a 4-percent-thick, unswept, tapered wing. The results indicate that the addition of tip tanks to the wing reduces the rolling effectiveness of the plain aileron but increases slightly the rolling effectiveness of the tip aileron over the test Mach number range from 0.6 to 1.5. Drag coefficient was increased by essentially the same amount for both control configurations by the addition of tip tanks.

NACA Rept. 1220

CALCULATIONS OF LAMINAR HEAT TRANSFER AROUND CYLINDERS OF ARBITRARY CROSS SECTION AND TRANSPIRATION-COOLED WALLS WITH APPLICATION TO TURBINE BLADE COOLING. E. R. G. Eckert and J. N. B. Livingood. 1955. ii, 21p. diagrs., tabs. (NACA Rept. 1220. Supersedes RM E51F22)

An approximate method for development of flow and thermal boundary layers in laminar regime on cylinders with arbitrary cross section and transpiration-cooled walls is obtained by use of Karman's integrated momentum equation and an analogous heat-flow equation. Incompressible flow with constant property values throughout boundary layer is assumed. Shape parameters for approximated velocity and temperature profiles and functions necessary for solution of boundary-layer equations are presented as charts, reducing calculations to a minimum. The method is applied to determine local heat-transfer coefficients and surface temperatures in the laminar region of transpiration-cooled turbine blades for a given flow rate. Coolant flow distributions necessary for maintaining uniform blade temperatures are also determined.

NACA Rept. 1228

CALCULATED SPANWISE LIFT DISTRIBUTIONS, INFLUENCE FUNCTIONS, AND INFLUENCE COEFFICIENTS FOR UNSWEPT WINGS IN SUBSONIC FLOW. Franklin W. Diederich and Martin Zlotnick. 1955. ii, 69p. diagrs., tabs. (NACA Rept. 1228. Supersedes TN 3014)

Spanwise lift distributions have been calculated for 19 unswept wings with various aspect ratios and taper ratios and with a variety of angle-of-attack or twist distributions, including flap and aileron deflections, by means of the Weissinger method with eight control points on the semispan. Also calculated were aerodynamic influence coefficients which pertain to a certain definite set of stations along the span, and several methods are presented for calculating aerodynamic influence coefficients for stations other than those stipulated.

NACA RM 56D27

STABILITY OF SYSTEMS CONTAINING A HEAT SOURCE - THE RAYLEIGH CRITERION. Boa-Teh Chu, Johns Hopkins University. June 1956. 25p. diagrs. (NACA RM 56D27)

The stability of systems containing a heat source is examined from the energy point of view. Rayleigh's criterion is derived. In the case of a flame, it is found that Rayleigh's criterion must be modified slightly if the specific-heat ratios γ of the burned and unburned gases are different.

NACA TN 3275

INVESTIGATION OF THE EFFECT OF IMPACT DAMAGE ON FATIGUE STRENGTH OF JET-ENGINE COMPRESSOR ROTOR BLADES. Albert Kaufman and André J. Meyer, Jr. June 1956. 25p. diagrs., photos. (NACA TN 3275)

Compressor rotor blades, which had suffered impact damage from a foreign object while being run in an axial-flow engine, were fatigue tested to determine the reduction in structural endurance. The most serious damage was nicks at the blade edges. The farther the damage was from the maximum-vibratory-stress section of the airfoil and from the edges the less detrimental it was. The strength of the dented blades was restored by reworking them.

NACA TN 3277

SPACE HEATING RATES FOR SOME PREMIXED TURBULENT PROPANE-AIR FLAMES. Burton D. Fine and Paul Wagner. June 1956. 26p. diagrs., tab. (NACA TN 3277)

Space heating rate measurements can yield information that is useful in characterizing turbulent combustion. For Bunsen burner flames stabilized over a field of pipe-induced turbulence, the space heating rate decreased with increasing linear flow and burner diameter, and was independent of pilot conditions. Calculated space heating rates, at 1-atmosphere pressure, were in the range of 2×10^7 to 6×10^7 Btu per cubic foot per hour. Turbulent burning velocities over the same flow range were correlated by linear velocity at constant burner diameter, but the variation with burner diameter could not be expressed by a simple correlation.

NACA TN 3279

EFFECT OF PHOSPHATE COATINGS ON TEMPERATURE OF METAL PARTS EXPOSED TO FLAME ENVIRONMENTS. George C. Fryburg, Norman H. Katz, and Sidney L. Simon. July 1956. 20p. diagrs., photo., tabs. (NACA TN 3279)

The effect of phosphate coatings on the temperature of metal specimens placed in a flame environment was investigated. Since flames contain large numbers of atoms and radicals that react on metal surfaces liberating heat, it was thought that a phosphate coating might decrease the temperature of the metal by poisoning the surface to these reactions. Temperature lowerings of about 100° to 200° F were obtained. These are shown to arise mainly from the high emittance (about 1) of the phosphate coating rather than from a poisoning action.

NACA TN 3644

LIFT AND MOMENT COEFFICIENTS FOR AN OSCILLATING RECTANGULAR WING-AILERON CONFIGURATION IN SUPERSONIC FLOW. Julian H. Berman. July 1956. 46p. diagrs. (NACA TN 3644)

The problem of a partial-span rectangular control surface, hinged at its leading edge and harmonically oscillating in supersonic flow, is treated by linearized flow theory. The velocity potentials for a wing-aileron configuration performing vertical translation, wing pitching, and aileron rotation are derived as power series in terms of a frequency parameter to the fifth power of the frequency of oscillation. Expressions for force and moment coefficients at any spanwise location are presented. These expressions are applied to a flutter study of a rectangular wing-aileron configuration with the aileron in different spanwise positions.

NACA TN 3654

PERFORMANCE ANALYSIS OF FIXED- AND FREE-TURBINE HELICOPTER ENGINES. Richard P. Krebs and William S. Miller, Jr. June 1956. 49p. diagrs. (NACA TN 3654)

Generalized performance charts are given for these engines and comparison is made of off-design specific fuel consumption, altitude performance, power-speed characteristics, and response times. Flight performance results for an assumed 30,000-pound helicopter powered by the fixed- and free-turbine engines are given. Flight range, hovering duration, and rates of climb are compared for the two power-plant installations. A comparison of the dynamic response and stability of both engines in combination with a rotor is included.

NACA TN 3675

THE EFFECTS OF COMPRESSIBILITY ON THE UPWASH AT THE PROPELLER PLANES OF A FOUR-ENGINE TRACTOR AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10[1]. Armando E. Lopez and Jerald K. Dickson. July 1956. 38p. diagrs., photos., tab. (NACA TN 3675. Supersedes RM A53A30a)

The upflow angles at the horizontal center lines of the propeller planes were measured at Mach numbers up to 0.92 on a wing-fuselage-nacelle combination and on an isolated nacelle. A comparison is made between the experimental and theoretical values of the variation of the upwash angle with angle of attack.

NACA TN 3682

TIME CORRELATOR FOR PROBLEMS IN AERODYNAMICS. George Tolmie Skinner, California Institute of Technology. June 1956. 32p. diagrs. (NACA TN 3682)

An instrument of fairly simple design for measuring time correlation functions of two stationary random electrical signals is discussed. It is intended primarily for use in problems connected with aerodynamically produced acoustic fields but has suitable properties for application to a rather wide range of aerodynamic problems involving turbulent fields. It has been designed and constructed with a view to economy and simplicity of operation and makes extensive use of the general statistical properties of the problems for which it is intended.

NACA TN 3686

EXPERIMENTAL MEASUREMENTS OF FORCES AND MOMENTS ON A TWO-DIMENSIONAL OSCILLATING WING AT SUBSONIC SPEEDS. Sherman A. Clevenson and Edward Widmayer, Jr. June 1956. 28p. diagrs., tab. (NACA TN 3686. Supersedes RM L9K28a)

Experimental results of lifts and moments about the quarter chord of a two-dimensional wing at subsonic Mach numbers are presented. A comparison of the experimental magnitude of the lift vector with the theory as given by Dietze showed good agreement. Comparisons of the moments and the quadrature component of lift with theory indicated that some refinements in the testing technique are necessary for the experimental determination of these quantities in the transonic range.

NACA TN 3695

AN ANALYSIS OF BUZZING IN SUPERSONIC RAM JETS BY A MODIFIED ONE-DIMENSIONAL NON-STATIONARY WAVE THEORY. Robert L. Trimpi. July 1956. 72p. diagrs., photos. (NACA TN 3695. Supersedes RM L52A18)

Experimental instantaneous pressure records of simulated ram-jet models without heat addition showed that they buzzed in a manner governed internally by quasi-one-dimensional (plane-wave) theory, a manner which is not compatible with the laws of the Helmholtz theory. A theory applicable to the buzzing problem was obtained through modification of the one-dimensional, unsteady-flow theory. Theoretical computations of the pressure-time curves agreed closely with the experimental records. A possible simulation of the buzzing in ram jets with combustion by the test of a cold-flow model in which a contraction in area replaces the combustion chamber is also discussed.

NACA TN 3698

PRELIMINARY INVESTIGATION OF SELF-EXCITED VIBRATIONS OF SINGLE PLANING SURFACES. Elmo J. Mottard. June 1956. 19p. diagrs., photos., tab. (NACA TN 3698. Supersedes RM L55J27)

The effect of various planing-surface shapes, conditions of restraint, loads, trims, and speeds on the occurrence of self-excited vibrations was sought. It was found that vibration occurs with high aspect ratio (order of 10) of the wetted portion with freedom in rise. It may occur without freedom in trim. Limiting the aspect ratio (by the use of dead rise or a pointed trailing edge, for example) tends to reduce or eliminate the vibrations. Data are presented for the range of variables likely to be encountered with airplane hydro-skis.

NACA TN 3702

MEASUREMENTS OF ATMOSPHERIC TURBULENCE OVER A WIDE RANGE OF WAVELENGTH FOR ONE METEOROLOGICAL CONDITION. Harold L. Crane and Robert G. Chilton. June 1956. 18p. diagrs., photo. (NACA TN 3702)

A power spectrum of gust vertical velocity over a wide range of wavelengths, 10 feet to 60,000 feet, has been obtained by a simultaneous set of measurements in flight. The method used, which had the advantage of not involving airplane transfer functions, proved to be practicable. The data were obtained on film records and the power spectrum was calculated by digital methods.

NACA TN 3703

THE FLOW PAST AN UNSWEPT- AND A SWEPT-WING—BODY COMBINATION AND THEIR EQUIVALENT BODIES OF REVOLUTION AT MACH NUMBERS NEAR 1.0. Walter F. Lindsey. June 1956. 18p. diagrs., photos. (NACA TN 3703. Supersedes RM L54A28a)

The complete flow fields past an unswept- and a swept-wing—body combination and their equivalent bodies of revolution at Mach numbers around 1.0 have been observed by means of motion-picture schlieren photography. The results of these observations indicate that the shock growth and positions on the wing-body combinations are closely reproduced in the flow past their respective equivalent bodies.

NACA TN 3705

AN INVESTIGATION OF FORWARD-LOCATED FIXED SPOILERS AND DEFLECTORS AS GUST ALLEVIATORS ON AN UNSWEPT-WING MODEL. Delwin R. Croom, C. C. Shufflebarger, and Jarrett K. Huffman. June 1956. 26p. diagrs., photo. (NACA TN 3705)

The present paper presents the results and discussion of an investigation in the Langley 300-MPH 7- by 10-foot tunnel and the Langley gust tunnel to determine the longitudinal aerodynamic characteristics and the gust-alleviation capabilities of forward-located fixed spoilers, deflectors, or spoiler-deflector combinations on a simulated transport airplane model having an unswept wing. Analysis indicates that a forward-located fixed deflector would be a practicable and an effective alleviator of gust loads when turbulence is encountered inasmuch as it reduces the normal accelerations, aids in slowdown, and requires small attitude and trim changes.

NACA TN 3707

FLUTTER OF THIN PROPELLER BLADES, INCLUDING EFFECTS OF MACH NUMBER, STRUCTURAL DAMPING, AND VIBRATORY-STRESS MEASUREMENTS NEAR THE FLUTTER BOUNDARIES. Harvey H. Hubbard, Marvin F. Burgess, and Maurice A. Sylvester. June 1956. 25p. diagrs., tab. (NACA TN 3707)

Experimental results are presented of an investigation on the flutter of thin propeller blades with three different plan forms. Flutter boundaries are presented for a highly twisted blade for which several modes of flutter were observed. Some effects of Mach number and structural damping on the flutter boundaries are described and it is noted that these effects may be beneficial in alleviating flutter. Vibratory-stress measurements in the region of the stall flutter boundary indicate that an increase in the internal blade damping is beneficial in reducing the magnitudes of the stresses.

NACA TN 3710

PRELIMINARY INVESTIGATION OF THE EFFECTS OF EXTERNAL WING FUEL TANKS ON DITCHING BEHAVIOR OF A SWEPTBACK-WING AIRPLANE. Ellis E. McBride. July 1956. 21p. diagrs., photos., tab. (NACA TN 3710)

An experimental investigation was made by use of a 1/10-scale dynamically similar model of a typical sweptback-wing airplane equipped with external wing fuel tanks to determine the effects of the tanks on the ditching behavior. The tanks used were of two fineness ratios, three fuel capacities, and various cross-section shapes. Data on the various tank configurations and on the basic model without tanks are presented in tabular form, time-history curves of acceleration and attitude, and sequence photographs.

NACA TN 3718

THEORETICAL WAVE DRAG OF SHROUDED AIRFOILS AND BODIES. Paul F. Byrd. June 1956. 40p. diagrs. (NACA TN 3718)

Formulas for the wave drag of shrouded symmetrical airfoils and shrouded bodies of revolution of arbitrary shape are derived by means of linearized theory. In the case of the airfoils, the shroud consists of flat plates and for the bodies of revolution the shroud is a cylindrical shell. The results obtained hold for a Mach number range dependent on the geometry of the configuration. Expressions are also given for determining a class of body shapes for which the wave drag is theoretically zero.

NACA TN 3719

APPLICATION OF SCATTERING THEORY TO THE MEASUREMENT OF TURBULENT DENSITY FLUCTUATIONS BY AN OPTICAL METHOD. Howard A. Stine and Warren Winovich. June 1956. 21p. diagrs., (NACA TN 3719)

It is shown that photometric measurements in the scattered field produced by passing an unpolarized plane light wave through a nonabsorbing turbulent fluid can be used to define an average integral scale and average intensity of density fluctuations. The analysis is based upon the scattering coefficient deduced by Booker and Gordon for a turbulence model possessing isotropic fluctuations and an exponentially decaying correlation function. A limited number of experimental results are presented which demonstrate the functional adequacy of the derivation.

NACA TN 3721

AN EVALUATION OF FOUR EXPERIMENTAL METHODS FOR MEASURING MEAN PROPERTIES OF A SUPERSONIC TURBULENT BOUNDARY LAYER. George J. Nothwang. June 1956. 34p. diagrs., photos. (NACA TN 3721)

Surveys were made through the flat plate turbulent boundary layer at a Mach number of 3 using a pitot probe, an X-ray densitometer, and cold-wire and hot-wire probes. The first three methods indicated consistent mean values of pitot pressure, density, and total temperature; the hot-wire probe, however, indicated larger values of mean mass flow. The assumption of constant total temperature through the boundary layer yielded negligible errors in velocity distribution, and displacement and momentum thicknesses.

NACA TN 3740

PRELIMINARY WIND-TUNNEL TESTS OF TRIANGULAR AND RECTANGULAR WINGS IN STEADY ROLL AT MACH NUMBERS OF 1.62 AND 1.92. Clinton E. Brown and Harry S. Heinke, Jr. June 1956. 36p. diagrs., tabs. (NACA TN 3740. Supersedes RM L8L30)

Damping-in-roll coefficients for a series of triangular plan-form wings and two rectangular plan-form wings have been obtained from supersonic-tunnel tests. The wings were mounted on a body of revolution and tested at Mach numbers of 1.62 and 1.92.

CHOKING EFFECTS AND SOME REYNOLDS NUMBER EFFECTS ON THE MACH NUMBER DISTRIBUTION ROUND A TWO-DIMENSIONAL AEROFOIL IN THE RAE 10-FT X 7-FT HIGH-SPEED TUNNEL. D. A. Clarke and H. E. Gamble. 1955. 30p. diagrs., photo., tabs. (ARC R & M 2912; ARC 13,123. Supersedes: RAE Aero 2337)

A two-dimensional airfoil of NACA 0015 section was tested at zero incidence. Measurements were made of (a) static pressure on the airfoil surface at Reynolds numbers of 1.4×10^6 to 5.5×10^6 and (b) static pressure on the airfoil surface, on the tunnel walls and in the stream between the airfoil and the walls at $R = 2.8 \times 10^6$. All tests were made at Mach numbers of 0.7 upwards and were continued past the choking Mach number of 0.764 until either the maximum permissible fan speed was reached or the maximum available power was being used.

MEASUREMENT OF LIFT, PITCHING MOMENT AND HINGE MOMENT ON A TWO-DIMENSIONAL CAMBERED AEROFOIL TO ASSIST THE ESTIMATION OF CAMBER DERIVATIVES. H. C. Garner and A. S. Batson. 1955. 34p. diagrs., tabs. (ARC R & M 2946. Supersedes: ARC 15,456; S & C 2709)

Aerodynamic camber derivatives are used in predicting three-dimensional control characteristics, in estimating wind-tunnel interference, and in applying model data to full scale. Experiments were performed to confirm empirical formulas for the derivatives of lift and pitching moment and to check widely differing formulas for the hinge-moment derivative. A two-dimensional airfoil (RAE 102) with a 4-percent parabolic center line and plain control surfaces of chord ratios 0.2 and 0.4 has been tested at low speed and RN of 0.95×10^6. Particular attention was given to boundary-layer transition. Aerodynamic coefficients were obtained from measured forces and moments and from the pressure distribution at one section.

N-44019*

Aeronautical Research Council (Gt. Brit.)
NOTES ON THE TRANSONIC MOVEMENT OF WING AERODYNAMIC CENTRE. S. B. Gates. 1956. 34p. diagrs., tabs. (ARC R & M 2785; ARC 12,430. Supersedes RAE Aero 2325)

These notes aim at providing a framework to display what is known of the backward movement of the aerodynamic center of wing shapes likely to be used for transonic operation, as the flow progresses from incompressible through subsonic to supersonic, the shock-wave regime being ignored. A new geometrical parameter δ is taken as the main variable because (a) it gives a neat classification of the various wing shapes, (b) it expresses the results of supersonic theory in a simple form, (c) it simplifies the subsonic analysis by making direct use of the similarity law for three-dimensional compressible flow, and so (d) it is possible to display on one diagram most of the theoretical and experimental data at present available.

Aeronautical Research Council (Gt. Brit.)
HINGE-MOMENT DERIVATIVES FOR AN OSCILLATING CONTROL. C. S. Sinnott. 1955. 11p. diagrs. (ARC R & M 2923. Supersedes ARC 15,670, 0.1044, S & C 2744 & ARC 16,130, 0.1044a, S & C 2744a)

The semiempirical "equivalent profile" method of W. P. Jones is extended to the case of an airfoil with an oscillating control. The oscillatory hinge-moment derivatives for such an airfoil-control combination in a low-speed wind tunnel are estimated, an allowance for tunnel wall interference effects being included. A comparison with measured values of the control derivatives is made for two values of the control chord ratio, representing an aileron and a tab. The method of this report gives results in much better agreement with experiment than those obtained by vortex-sheet theory.

AN EXPERIMENTAL INVESTIGATION OF A THICK-AEROFOIL NOZZLE CASCADE. S. J. Andrews and N. W. Schofield. 1956. 13p. diagrs., photos., tab. (ARC R & M 2883; ARC 13,632. Supersedes NGTE Memo.M.84)

The cascade tests on a thick-airfoil turbine nozzle blade suitable for a cooled turbine show that it has a good performance over a wide incidence range up to $M = 0.8$. Above this value the loss coefficient rises and does not fall again as $M = 1$ is approached. Several methods of indication of the transition point have been tried and results show that the method depending on the evaporation of crystals gives a position inconsistent with three other methods, that is, lamp-black deposit, surface total-head measurement, and stethoscope search tube. The effect of the thick trailing edge on loss coefficient is almost that predicted assuming zero velocity behind the blade trailing edge. The heat-transfer increase due to transition is probably not large, and is no worse than that on a conventional turbine section.

AEROFOIL DESIGN IN TWO-DIMENSIONAL SUBSONIC COMPRESSIBLE FLOW. L. C. Woods. 1955. 54p. diagrs., tabs. (ARC R & M 2845. Supersedes ARC 14,708, FM 1688)

The method of two-dimensional airfoil design in incompressible flow due to Lighthill is extended to compressible subsonic flow. Lighthill's equations are derived as special cases of more general equations due to the author, and some advances are made in the application of these equations to airfoil design. The method of reference 1 requires that the velocity distribution be prescribed analytically, whereas this paper deals with distributions defined numerically. The compressible flow theory is based on an approximation to the equation of flow not unlike the Kármán-Tsien approximation for calculating the flow about a given airfoil. A method of estimating the effects of a modification to the designed airfoil shape on the velocity distribution is also given. Five examples have been calculated.

WIND-TUNNEL FLUTTER TESTS ON A MODEL DELTA WING UNDER FIXED AND FREE ROOT CONDITIONS. D. R. Gaukroger, E. W. Chapple, and A. Milln. 1955. 10p. diagrs., tab. (ARC R & M 2826; ARC 13,721. Supersedes RAE Structures 89)

Wind-tunnel tests on a model wing of delta plan form are described. Tests have been made with the wing root fixed and also with the root free in pitch and vertical translation. Critical flutter speed and frequency are given for a wide range of variation of wing and fuselage inertia parameters. The results show that, under root-free conditions, body freedom flutter occurs at low values of fuselage pitching moment of inertia, but that at higher values the flutter is similar to that obtained with root-fixed conditions.

ANALYSIS OF REYNOLDS NUMBER EFFECTS IN FLUID FLOW THROUGH TWO-DIMENSIONAL CASCADES. D. J. K. Stuart. 1955. 39p. diagrs., tab. (ARC R & M 2920; ARC 15,260)

In this report particular emphasis has been placed on the causes of high loss, especially at very low Reynolds numbers. Separation of both the laminar and turbulent boundary layers is verified as sources of low efficiency in this particular type of flow and these phenomena have been studied in considerable detail. Mach number effects were specifically avoided in the experimental work although a wide range of Reynolds number was covered (RN = 30,000 to 500,000); the effect of compressibility has not been considered in the main analysis. It is shown that design methods can be modified to insure improved performance at a specified Reynolds number or over a range of Reynolds numbers.

TESTS IN THE R.A.E. 10-FT x 7-FT HIGH SPEED WIND TUNNEL ON DROP TANKS FITTED TO TWO SWEPT-BACK WINGS. PART I. COMPARISON OF UNDER-WING AND WING-TIP INSTALLATIONS. D. E. Hartley and A. B. Haines. PART II. COMPARISON OF VARIOUS UNDER-WING DROP-TANK ARRANGEMENTS. By Staff of R.A.E. High Speed Wind Tunnel. 1956. 45p. diagrs., photos., tabs. (ARC R & M 2951; ARC 14,653; ARC 15,402. Supersedes RAE Aero 2442 & RAE Tech.Note Aero 2177)

Two wings, having the same plan form with a sweepback of 40° and an aspect ratio of 3.5, but differing in thickness/chord ratio, being 10 percent and 8.5 percent thick, respectively, were tested. Part 1 compares the results obtained with the drop tanks mounted in two alternative positions on the 10 percent thick wing: under the wing at about midsemispan, supported by an 8.5 percent thick strut or at the wing tip in a midwing position. Part 2 compares the results obtained with several different types of underwing installation, for example, with different designs of strut or alternatively dispensing with the strut and fitting the tanks directly on to the lower surface of the wing. Most of the tanks had a fineness ratio of 8:1.

THE THEORY OF TORSIONAL VIBRATIONS OF A FOUR-BOOM THIN-WALLED CYLINDER OF RECTANGULAR CROSS-SECTION. E. H. Mansfield. 1955. 16p. diagrs., tab. (ARC R & M 2867; ARC 14,024. Supersedes RAE Structures 103)

Torsional vibrations of a four-boom cylinder of doubly symmetrical rectangular cross section are considered and the differential equation of motion is derived on the assumption that the ribs maintain the section shape but do not themselves resist any warping out of their plane and that the walls of the cylinder are effective only in shear. Frequency equations are derived for a length of cylinder, free at both ends and prevented from rotating at the midsection. Complete behavior of the cylinder is determined by two nondimensional parameters; curves are given from which the frequencies for any such cylinder may be determined. Higher frequencies in particular may be underestimated by between 40 to 80 percent if warping constraint effects are ignored. An approximate method is given for estimating the torsional frequencies of a cylinder with nonuniform characteristics.

THE CALCULATION OF THE LOADING AND PRESSURE DISTRIBUTION ON CRANKED WINGS.
G. G. Brebner. 1955. 31p. diagrs., tab. (ARC R & M 2947; ARC 15,933. Supersedes RAE Aero 2483)

Using distributions of vortices and sources over the airfoil surface, approximate formulas are developed for finding the spanwise and chordwise loadings of cranked wings (i. e., wings with discontinuous changes of sweep), and the chordwise pressure distribution at the crank, in incompressible flow. The method can be extended to subcritical compressible flow by considering the "analogous wing." Calculations by the present method are compared with experimental results on two wings and with calculations by another method for wings of M, W, and Λ plan form. Agreement with experiment is good. Comparison with the other method shows satisfactory agreement between the spanwise loadings, but the present method yields more information about chordwise distributions, and is quicker.

THEORETICAL REQUIREMENTS OF TUNNEL EXPERIMENTS FOR DETERMINING STABILITY DERIVATIVES IN OSCILLATORY LONGITUDINAL DISTURBANCES. S. Neumark and A. W. Thorpe. 1955. 14p. diagrs. (ARC R & M 2903; ARC 13,667. Supersedes RAE Tech.Note Aero 2059)

The need of using stability derivatives of unsteady (oscillatory) motion is explained, and requirements of tunnel experiments for determining them are established. These are based on simple theoretical considerations, valid for both incompressible and compressible (subsonic and supersonic) flow. Two alternative schemes of experimental tests are critically examined. *Nondimensional derivatives* are defined and applied in modified stability equations, referred to fixed or moving systems of coordinate axes.

ROLLING POWER MEASUREMENTS AND COMPARATIVE CALCULATIONS FOR A FLEXIBLE MODEL WING CONSTRUCTED FROM XYLONITE.
N. C. Lambourne, A. S. Batson, and A. Chinneck.
Appendix: APPLICATION OF LIFTING LINE THEORY. H. C. Garner. 1955. 35p. diagrs., photos., tabs. (ARC R & M 2895. Supersedes ARC 13,322, 0.884, S & C 2422 & ARC 14,608, 0.884a, S & C 2422a)

Partly to gain experience of aeroelastic models constructed from Xylonite, and partly to provide information regarding loss of rolling power due to wing distortion, a tip-to-tip model of the wings of a Spitfire aircraft was constructed. It was mounted on a longitudinal axis in a wind tunnel so that it could roll continuously. Rates of rolling were measured for a range of airspeeds and the results are compared with those of calculations. The variation of rolling power with airspeed was calculated by (a) the Collar and Broadbent method which is based on strip theory and (b) a method developed by H. C. Garner based on lifting-line theory.

A FULL-SCALE INVESTIGATION INTO THE HYDRODYNAMIC BEHAVIOUR OF A HIGHLY FAIRED FLYING-BOAT HULL. J. A. Hamilton. 1956. 36p. diagrs., photos., tab. (ARC R & M 2899; ARC 15,196. Supersedes MAEE F/Res/223)

This report describes an investigation into the hydrodynamic qualities of a Sunderland flying-boat hull, weight 50,000 pounds, fitted with a main-step fairing of fairing ratio 17:1. The fairing was equipped with ventilating ducts, drawing air at atmospheric pressure through ports on the hull side, and discharging it through exit vents on the afterbody planing bottom. No pumping apparatus was fitted, the air flow being induced by the subatmospheric pressures on the fairing. The general conclusion of the investigation is that successful hulls may be designed without conventional steps, provided that sufficient internal ventilation is provided.

THE EFFECT OF IMPEDANCE MISMATCH ON THE FREQUENCY RESPONSE OF A SUPERHET RECEIVER. M. B. Barnes. December 1955. 18p. diagrs., tabs. (RAE Tech.Note GW 392)

In this note the effects of impedance mismatches between crystal mixer, preamplifier, and I. F. amplifier on the frequency response of a superhet receiver are described. The method of measuring and matching the output impedance of the mixer crystal is described. A sensitive method of estimating the input impedance of the I. F. amplifier, and of matching it to the Z_0 of the input cable, is developed. This method could equally well be used to form an estimate of the output impedance of the preamplifier. It was necessary to take special matching precautions to achieve an overall frequency response which was smooth and flat-topped to within 0.1 db over the band 44-46 mc/s when the mixer, preamplifier, and I. F. amplifier were separated by long lengths of cable. The Appendix gives details of the X Band wobbulation method used for adjusting the overall frequency response of the receiver.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1252

QUASI-CYLINDRICAL THEORY OF WING-BODY INTERFERENCE AT SUPERSONIC SPEEDS AND COMPARISON WITH EXPERIMENT. Jack N. Nielsen. 1955. ii, 56p. diagrs., tabs. (NACA Rept. 1252. Supersedes TN 2677; TN 3128)

A theoretical method is presented for calculating the flow field about wing-body combinations employing bodies deviating only slightly in shape from a circular cylinder. The method is applied to the calculation of the pressure field acting between a circular cylindrical body and a rectangular wing. The case of zero body angle of attack and variable wing incidence is considered as well as the case of zero wing incidence and variable body angle of attack. An experiment was performed especially for the purpose of checking the calculative examples.

NACA RM E56E11

USE OF TRUNCATED FLAPPED AIRFOILS FOR IMPINGEMENT AND ICING TESTS OF FULL-SCALE LEADING-EDGE SECTIONS. Uwe H. von Glahn. July 1956. 29p. diagrs., photos., tabs. (NACA RM E56E11)

Experimental studies were made with an NACA 65_1-212 airfoil section truncated at the 30- and 50-percent-chord stations and equipped with a trailing-edge flap. When the truncated airfoils were compared with the full-chord airfoils, the velocity distribution and the impingement characteristics were similar with the flap properly deflected, but were altered substantially without flap deflection. Use of flapped truncated airfoils permits impingement and icing studies in icing tunnels to be conducted with full-scale leading-edge sections over a greater range of conditions than previously possible.

NACA RM L56C27

STATIC-THRUST CHARACTERISTICS OF THE NACA 8.75-(5) (05)-037 DUAL-ROTATION PROPELLER. Harry T. Norton, Jr. July 1956. 16p. diagrs., photo. (NACA RM L56C27)

This paper presents the static-thrust characteristics of the NACA 8.75-(5) (05)-037 dual-rotation propeller having six and eight blades.

NACA RM L56D16

ZERO-LIFT DRAG OF A SERIES OF BOMB SHAPES AT MACH NUMBERS FROM 0.60 TO 1.10. William E. Stoney, Jr., and John F. Royall. July 1956. 12p. diagrs., photos., tabs. (NACA RM L56D16)

Zero-lift drag data were obtained on a series of six bomb shapes. Five configurations had the same body shape, the only difference being in the body-surface conditions and the profile and plan form of the fins, while the sixth configuration had a different and longer body shape. The models were launched from a helium gun (at the Langley Pilotless Aircraft Research Station at Wallops Island, Va.), and data were obtained for Mach numbers from 0.60 to 1.10 with corresponding Reynolds numbers based on body length of 5×10^6 to 10×10^6. It was found that at subsonic speeds the blunt trailing edge of the fins contributed a large share of the drag while the effect of the blunt leading edge was negligible. Two models whose roughness did not exceed 20 rms microinches had measurably lower subsonic drag coefficients than the remaining models whose roughness varied between 100 and 250 rms microinches.

NACA TM 1422

ON LANDING GEAR STRESSES. (Sur les Sollicitations des Atterrisseurs). A. Gentric. July 1956. 45p. diagrs., photos. (NACA TM 1422. Trans. from Docaéro, no.25, January 1954, p.17-38).

This paper presents the French viewpoint on ground loads problems and discusses their current efforts and new research equipment. Some data are presented on tangential forces due to wheel spin-up effects and on longitudinal oscillations of landing gears. The subject of fatigue failures resulting from longitudinal oscillations is discussed and several case histories are presented. Overall suggestions for improvement in landing-gear design techniques are given and the areas where additional research is needed are indicated.

NACA TN 3688

STATIC-THRUST MEASUREMENTS OF THE AERODYNAMIC LOADING ON A HELICOPTER ROTOR BLADE. John P. Rabbott, Jr. July 1956. 22p. diagrs., photos. (NACA TN 3688)

Plots of the chordwise and spanwise aerodynamic loading measured on a helicopter rotor blade in static

thrust are presented. A comparison of the spanwise loading with the strip-analysis theoretical loading, as modified by a simple correction for the number of blades, shows fair agreement. The data also suggest that a tip-loss factor for performance calculations should be a function of the thrust coefficient, rather than a constant factor.

NACA TN 3701

COMPARISON OF SEVERAL METHODS FOR OBTAINING THE TIME RESPONSE OF LINEAR SYSTEMS TO EITHER A UNIT IMPULSE OR ARBITRARY INPUT FROM FREQUENCY-RESPONSE DATA. James J. Donegan and Carl R. Huss. July 1956. 39p. diagrs., tabs. (NACA TN 3701)

Several methods of obtaining the time response of linear systems to either a unit impulse or an arbitrary input from frequency-response data are described and compared. Comparisons indicate that all of the methods give good accuracy when applied to a second-order system; the main difference is the required computing time to obtain the same degree of accuracy. When applied to higher order systems, however, the methods generally classified as inverse Laplace transform methods were found most effective. Some discussion is given of the use of the methods as flight-data-analysis techniques in predicting loads and motions for a flexible aircraft when the aircraft frequency response is known.

NACA TN 3706

INVESTIGATION OF THE LAMINAR AERODYNAMIC HEAT-TRANSFER CHARACTERISTICS OF A HEMISPHERE-CYLINDER IN THE LANGLEY 11-INCH HYPERSONIC TUNNEL AT A MACH NUMBER OF 6.8. Davis H. Crawford and William D. McCauley. July 1956. 38p. diagrs., photos. (NACA TN 3706)

A program to investigate the aerodynamic heat transfer of a nonisothermal hemisphere-cylinder has been conducted in the Langley 11-inch hypersonic tunnel at a Mach number of 6.8 and a Reynolds number from approximately 1.09×10^5 to 1.03×10^6 based on diameter and free-stream conditions. The experimental heat-transfer coefficients were slightly less over the whole body than those predicted by the Stine and Wanlass theory (NACA TN 3344) for an isothermal surface. For stations within 45° of the stagnation point the heat-transfer coefficients could be correlated by a single relation between local Stanton number and local Reynolds number.

NACA TN 3717

THREE-DIMENSIONAL TRANSONIC FLOW THEORY APPLIED TO SLENDER WINGS AND BODIES. Max. A. Heaslet and John R. Spreiter. July 1956. 72p. diagrs. (NACA TN 3717)

Integral equations for transonic flow around slender wings and bodies are derived assuming shock waves are present. For sonic flow, Oswatitsch's equivalence rule is extended to lifting cases at small angles of attack. Relationships are presented between the pressure distributions and integrated forces on slender wings and bodies having the same longitudinal distribution of cross-section area. Specific application is made to slender cone-cylinders of elliptic cross sections of varying eccentricity. The conclusions are supported both by formal analysis of the order of the error terms and by comparison with existing theoretical and experimental information.

NACA TN 3731

TENSILE PROPERTIES OF INCONEL AND RS-120 TITANIUM-ALLOY SHEET UNDER RAPID-HEATING AND CONSTANT-TEMPERATURE CONDITIONS. George J. Heimerl, Ivo M. Kurg, and John E. Inge. July 1956. 29p. diagrs., photo., tabs. (NACA TN 3731)

Results are presented of rapid-heating tests to determine the tensile strength of Inconel and RS-120 titanium-alloy sheet heated to failure at uniform temperature rates from 0.2° F to 100° F per second under constant load conditions. Yield and rupture stresses, obtained by rapid heating, are conpared with yield and ultimate stresses from elevated-temperature tensile stress-strain tests for 1/2-hour exposure. The applicability of master curves and temperature-rate parameters to the prediction of yield and rupture stresses and temperatures under rapid-heating conditions was investigated.

NACA TN 3732

AN INVESTIGATION OF VERTICAL-WIND-SHEAR INTENSITIES FROM BALLOON SOUNDINGS FOR APPLICATION TO AIRPLANE- AND MISSILE-RESPONSE PROBLEMS. H. B. Tolefson. July 1956. 33p. diagrs., tabs. (NACA TN 3732)

The daily upper-wind soundings taken at one station for a one-year period are analyzed to obtain data on the vertical-wind-shear intensities and frequencies for use in airplane- and missile-response studies. The results indicated maximum shear intensities of about 100 meters per second per kilometer occurring at altitudes from 10 to 15 kilometers during the winter and spring months. The application of these results to the calculation of the normal response of a missile in vertical flight is also considered briefly.

NACA TN 3734

TURBULENT-HEAT-TRANSFER MEASUREMENTS AT A MACH NUMBER OF 3.90. Maurice J. Brevoort. July 1956. 15p. diagrs., tab. (NACA TN 3734)

An axially symmetric annular nozzle was used to obtain essentially flat-plate data on turbulent-heat-transfer coefficients and temperature-recovery factors. The test results of this paper are for a Mach number of 3.90 and for a Reynolds number range of 6.3×10^5 to 7.0×10^7. The heat-transfer-coefficient results are slightly higher than theoretical results for a Mach number of 4.0. The recovery factors show a decrease with Reynolds number from approximately 0.89 at 6.3×10^5 to approximately 0.86 at 7.0×10^7.

NACA TN 3735

BENDING TESTS OF RING-STIFFENED CIRCULAR CYLINDERS. James P. Peterson. July 1956. 14p. diagrs., photos., tab. (NACA TN 3735)

Twenty-five ring-stiffened circular cylinders were loaded to failure in bending. The results are presented in the form of design curves which are applicable to cylinders with heavy rings that fail as a result of local buckling.

NACA TN 3739

FLIGHT INVESTIGATION OF THE PERFORMANCE OF A TWO-STAGE SOLID-PROPELLANT NIKE-DEACON (DAN) METEOROLOGICAL SOUNDING ROCKET. Robert H. Heitkotter. July 1956. 21p. diagrs., photos. (NACA TN 3739)

A flight investigation of two Nike-Deacon (DAN) two-stage solid-propellant rocket vehicles indicated satisfactory performance may be expected from the DAN meteorological sounding rocket. Peak altitudes of 356,000 and 350,000 feet, respectively, were recorded for the two flight tests when both vehicles were launched from sea level at an elevation angle of 75°. Performance calculations based on flight-test results show that altitudes between 358,000 feet and 487,000 feet may be attained with payloads varying between 60 pounds and 10 pounds.

NACA TN 3756

STUDY OF SIZE EFFECT IN SHEET-STRINGER PANELS. J. P. Doman and Edward B. Schwartz, Naval Air Material Center. Appendix B: STATISTICAL ANALYSIS. Edward B. Schwartz. July 1956. 25p. diagrs., photos., tabs. (NACA TN 3756)

An investigation was conducted to determine whether there are significant size effects in compressive strength of large Z-stiffened sheet-stringer panels as compared with geometrically similar smaller models and thus to ascertain whether the prediction of the strength of large panels by model tests is reliable. The specimens studied were manufactured from 7075-T6 aluminum alloy and included four representative types of panel designs, with full- and one-quarter-scale panels of each type.

CORRELATED FATIGUE DATA FOR AIRCRAFT STRUCTURAL JOINTS. R. B. Heywood. 16p. diagrs., tab. (ARC CP 227)

Results of fatigue tests carried out at R. A. E. on typical aircraft wing structural joints are correlated to give an indication of general fatigue behavior. The results are plotted in the form of S - Log N curves, and these indicate that the mode of behavior cannot be attributed to any single factor, such as the type of aluminum alloy, the ultimate tensile strength, or the mean stress of the fatigue cycle. The detailed method of design undoubtedly has a predominant influence on behavior, but this quality is not revealed by a broad classification according to the proportion of load transmitted at holes.

LOADING CONDITIONS FOLLOWING AN AUTOMATIC PILOT FAILURE (ELEVATOR CHANNEL). D. R. Puttock. 1956. 50p. diagrs. (ARC CP 243)

A proposal is made for a standard procedure for calculating the critical loading conditions ensuing from an automatic pilot failure in the elevator channel. General expressions are derived through response theory for the increments in normal acceleration at the c. g. of the aircraft, normal acceleration at the tail, and aerodynamic load on the tail plane which result from the sequence of elevator movements assumed to follow a failure. Analysis of these general expressions leads to formulas suitable for assessing the numerical values of the critical loads on the wing and tail plane. The influence of the sequence of elevator movements on the loading conditions is discussed with reference to an example.

INVESTIGATION OF THE FATIGUE OF EXTRUDED TUBULAR BOOMS. W. A. P. Fisher and H. Yeomans. 1956. 15p. diagrs., photos., tabs. (ARC CP 234)

Three types of specimen made from aluminum alloy DTD 364 were tested and the results compared. The types of specimen were: (a) extruded tube specimens lightly machined on the outside - having transverse holes drilled through the tube (these represented the critical section of the Viking replacement and Valetta spar boom), (b) plain extruded tube with the center portion reduced to ensure failure in the test section, and (c) solid polished bar specimens made from the walls of the extruded tubes. The results showed that the fatigue strength of the plain tube, with the original extruded bore, was less than half that of the polished bar. Fatigue cracking started in every tube from an obvious flaw on the inner surface.

Aeronautical Research Council (Gt. Brit.)
THE LAMINAR BOUNDARY-LAYER WITH DISTRIBUTED SUCTION ON AN INFINITE YAWED CYLINDER. K. D. P. Sinha. 1956. 54p. diagrs., tabs. (ARC CP 214)

Rott and Crabtree have considered the chordwise boundary-layer flow on a yawed infinite cylinder with chordwise stream velocity $U = cx^m$. They showed that this yields "similar" velocity distributions, and when there is no suction, the spanwise velocity profiles are approximately coincident with the exact Blasius profile, on a scale determined by the ratio of the normal coordinate to the momentum thickness. This phenomenon has been further examined, and an explanation of it is given. The work has been further extended to the case of distributed suction: and numerical solutions have been obtained for the spanwise flow for those cases for which the chordwise solutions were available. Exact analytical solutions of the spanwise flow have also been obtained. The effect of suction on the momentum thickness and displacement thickness is discussed. Finally, the behavior of the spanwise flow in the boundary layer is compared with the chordwise flow, and certain conclusions are drawn for varying pressure gradients.

A CORRECTED SPEED TACHOSCOPE. R. Staniforth. 1956. 15p. diagrs., photos. (ARC CP 224)

It is often desirable in testing aerodynamic compressors to take all readings at fixed corrected speeds rather than true speeds. This corrected speed is defined as the actual shaft speed divided by the square root of the ratio of the absolute air inlet temperature to the standard temperature (288° K). With the instrument described, this is possible with high accuracy (error < 0.1 percent) without further complication than the setting of a dial to the observed air inlet temperature. The latter operation could be dispensed with and the correction obtained directly from a temperature sensitive device such as a thermistor or a resistance thermometer element.

PRESSURE-CABIN DESIGN. A DISCUSSION OF SOME OF THE STRUCTURAL PROBLEMS INVOLVED, WITH SUGGESTIONS FOR THEIR SOLUTION. D. Williams. 51p. diagrs., tab. (ARC CP 226)

The problems that arise in the design of a pressure cabin are almost entirely due to the numerous structural discontinuities that inevitably break up the otherwise smooth distribution of stress. Some of the main discontinuities, such as are caused by windows, doors, canopies, floors, formers, bulkheads, and domes, are discussed here, and design suggestions are made for dealing with them. Particular attention is called to Appendix D and the Addendum based on it, which refers to a scheme for making pressure cabins safe against catastrophic failure with little weight penalty.

DEVELOPMENT OF AN AIR MASS-FLOW RATE METER. W. J. G. Cox. 1956. 47p. diagrs., photos. (ARC CP 230)

The development of a meter to cover a very wide range is described which, essentially an analog computer, gives a two-sweep pointer direct presentation of air mass-flow rate, independent of pressure, temperature, and velocity changes within the range of the instrument. The pointers are driven by a servo system which is error-actuated from the computing bridge network, secondary feedback being employed to maintain stability with a saturated angular output rate of approximately 33° per second. Specifications and performance figures are given for the individual transducer elements and the complete instrument, error estimates are made, and the servo stability is discussed.

AN AUTOMATIC SELF-BALANCING CAPSULE MANOMETER. G. F. Midwood and R. W. Hayward. 1956. 21p. diagrs., photos. (ARC CP 231)

A brief description is given of an automatic self-balancing capsule manometer which has been developed primarily for the measurement of pressures encountered in the operation of supersonic wind tunnels. A remote indicating system is employed which is suitable for use with digital recording and card punching apparatus. The instrument is designed to cover a range of 0-2 atmospheres absolute and has been adjusted and calibrated to give an accuracy of 0.01 inch Hg over the range 0.5 inch Hg to 60 inches Hg absolute.

Aeronautical Research Council (Gt. Brit.)
THE EFFECT OF LACING WIRE ON AXIAL COMPRESSOR STAGE PERFORMANCE AT LOW SPEEDS. S. J. Andrews and H. Ogden. 1956. 21p. diagrs. (ARC CP 225)

Four stages of free vortex blades were tested at low speed in the 106 compressor to determine the effects of lacing wire upon stage efficiency and temperature rise. With lacing wire of 0.14 in. diameter in the rotor and stator, and with blades of height $2\frac{1}{2}$ in., the loss in stage efficiency is about 12 percent, but if 0.14-in. diameter tubular lacing is deformed within the blade pitch to a more streamlined section of $2\frac{1}{2}$:1 fineness ratio, the drop in stage efficiency would be about 5 percent. It is estimated that for the circular wire 30 percent of the increase in loss is due to the wire drag itself and 70 percent is due to interference by the wire in the normal blade flow.

THE BUCKLING UNDER LONGITUDINAL COMPRESSION OF A SIMPLY SUPPORTED PANEL THAT CHANGES IN THICKNESS ACROSS THE WIDTH. E. C. Capey. 1956. 26p. diagrs. (ARC CP 235)

An exact solution is obtained for the buckling under longitudinal compression of a simply supported panel made up of three strips in which the central strip differs in thickness from the outer strips. The critical buckling stress is calculated numerically for a number of different ratios between thicknesses and widths of the central and outer strips. Some comparative results are given for the case when the longitudinal edges are clamped.

METHODS FOR REDUCING SEAPLANE TAKE-OFF DISTANCES TO STANDARD CONDITIONS. J. A. Hamilton. 1955. 45p. diagrs., photos., tabs. (ARC CP 219)

Methods for reducing seaplane take-off distances to standard conditions of weight, wind, and ambient temperature are developed which are applicable to the waterborne run and to the airborne run up to the 50 ft height point. The methods may be applied to take-off with simulated engine failure. Theoretical results are in good agreement with measurements made on reciprocating engined seaplanes of 9000 lb and 78,000 lb weight for winds up to 20 knots, weight changes of 20 percent and a temperature range of 2 to 32° C. The general application of the corrections should be limited to temperature changes of less than 10° C and wind changes of less than 10 knots. These ranges should be adequate for the majority of flight trials conducted in one location.

VELOCITY CALCULATIONS BY CONFORMAL MAPPING FOR TWO-DIMENSIONAL AEROFOILS. D. A. Spence and N. A. Routledge. 1956. 47p. diagrs., tabs. (ARC CP 241)

A method is derived for computing the conformal transformation between the plane of an airfoil of arbitrary shape (symmetrical or cambered), and the plane of its velocity potential at zero lift (in which the airfoil contour becomes a slit), in order to permit calculations of the velocity at points off the surface. The integral equation which relates the contours is derived by an application of Cauchy's theorem, and solved to the order of the square of thickness ratio. The solution is found by representing the ordinate distribution by a Fourier series. The rapid tailing-off of the Fourier coefficients for all smooth airfoil shapes then leads to high accuracy being achieved with a comparatively small amount of effort.

VARIATIONS IN THE STRENGTH OF ALUMINUM ALLOY SHEET. D. T. Jones. 1956. 10p. diagrs. (ARC CP 229)

In the design of aircraft structures, allowance is made for variation in the material strength of sheet, but the thickness of the sheet is usually assumed to be constant at the nominal value for the gage used. Thickness variation may appreciably affect the tensile strength of nominally identical pieces of sheet, especially when the tolerance range in thickness is wide. A method is given in this note for calculating the distribution of strength when the mean and scatter of material strength and the mean and scatter of thickness of pieces are known. Expressions are given for the mean and scatter in strength of pieces and, for those cases where the distribution of the strength can be taken as normal, design values can readily be deduced from the expressions.

Aeronautical Research Council (Gt. Brit.)
LOADING CONDITIONS FOLLOWING AN AUTOMATIC PILOT FAILURE (RUDDER CHANNEL). D. R. Puttock. 1956. 35p. diagrs., tab. (ARC CP 242)

A method is presented for the determination of the critical loading conditions of aircraft that ensue

from an automatic pilot failure in the rudder channel. General expressions have been derived through response theory for the angle of sideslip, fin-and-rudder load and lateral acceleration both at the c.g. of the aircraft and at the tail, that result from the sequence of rudder movements assumed to follow an automatic pilot failure. Analysis of these general expressions leads to formulas suitable for assessing the numerical values of the critical loading conditions, and it is suggested that these formulas might form a basis for the interpretation of the appropriate design requirement. An example is given to illustrate the type of response produced by a rudder channel failure and the calculation procedure.

REPORT OF THE FIRST YEAR'S FLYING ON THE DEVELOPMENT OF FLIGHT TESTING TECHNIQUES FOR FINDING AND MEASURING NATURAL ICING CONDITIONS. G. C. Abel. 1956. 44p. diagr., photos., tabs. (ARC CP 221)

Results of the first year's flying using a Viking aircraft are given. Special meteorological forecasts of icing conditions have proved to be reasonably reliable. Good photographs of droplets that have been sampled from a cloud can now be obtained at will and they give direct measurement of droplet sizes although, when frozen particles and supercooled droplets are present together, the interpretation of the photograph is still subject to doubt. The rotating disk ice accretion meter, especially when coupled to a Hussenot recorder, has proved, within certain limitations, to be a valuable instrument for measuring both the liquid water content of the cloud and the rate at which ice is building up. The immediate program is outlined and the future program discussed.

FILAMENT LAMP FAILURES IN AIRCRAFT. J. W. Sparke. August 1955. 4p. (RAE Tech. Note EL. 100)

The failure rates of filament lamps in aircraft are becoming excessive, particularly in the rear fuselage and tail region of jet aircraft. It is believed that the primary cause of failure is due to vibration at frequencies above 150 cps. It is not possible to design 28 volt filament lamps to withstand these conditions and the best solution appears to be to use anti-vibration mountings for the lighting fittings. The use of a lower voltage supply for small wattage lamps would improve reliability.

FATIGUE TESTS ON MATERIAL TO SPECIFICATION B. A. C. E. 54 (D. T. D. 551). P. J. Frith. October 18, 1954. 18p. diagrs., photos., tabs. (Ministry of Supply. S & T Memo.16/55)

The tests reported show that material DTD 551 and heat treated to B.A.C.E. specification 54 has excellent mechanical properties with relation to crankshaft design. The high proof stress values, good fatigue properties, particularly in the presence of stress concentration after nitriding, and satisfactory surface hardness in the nitrided condition are eminently suited for highly stressed parts subjected to repeated or alternating loading. Under conditions of combined bending and torsion, the safe stress range for any combination may be calculated with confidence, provided the fatigue limits in bending and torsion have been determined with care.

STUDY OF THE FATIGUE PROPERTIES OF SHEET CONFORMING TO SPECIFICATIONS DTD.546B AND DTD.646B WHICH HAS BEEN COLD FORMED TO Z SECTION. 14p. diagrs., photos., tabs. (Ministry of Supply. S & T Memo.18/55)

This report shows that the fatigue strength of Alclad material, DTD 546B was on the average lower than that of uncoated material, DTD 646B, when complete sections were tested, although the results were confused by considerable scatter. At an endurance of 2×10^6 cycles the fatigue strength of DTD 546B sections was ± 4.0 tons/sq in. compared with ± 5.0 tons/sq in. for DTD 646B material. The fatigue strength of the latter sections was approximately the same as that obtained from tests on unmachined Z section extrusion of material conforming to specification DTD 364B. Reversed bending fatigue tests were carried out on small coupons cut from the webs of the sections. The fatigue strength as determined from these tests was higher than that obtained from the complete sections.

THE INVESTIGATION OF IMPROVED METHODS OF ULTRASONIC FLAW DETECTION. D. O. Sproule and L. H. Wells. 1955. 26p. diagrs., photos. (Ministry of Supply. S & T Memo.19/55)

This report describes the methods evolved for more reliable testing of billets and the extension of these to tackle new materials including cast iron, copper, refractory blocks, and brass billets, which previously were impossible or difficult to inspect with ultrasonics. Single probe and double probe working is discussed. It is shown that both techniques are necessary if a wide range of problems is to be tackled and that any industrial instrument should enable either to be used. Examples are given of a wide range of new probes now available including waterproof types for immersion testing. An alternative form of presentation is described in which a picture in many ways similar to a radiograph is obtained.

THE MEASUREMENT AND ASSESSMENT OF REPEATED LOADS ON AIRPLANE COMPONENTS. Philip Donely. (Presented to the 3rd meeting of the Structures and Materials Panel of Advisory Group for Aeronautical Research and Development, Langley Field, Virginia, April 12, 1956). 37p. diagrs.

An attempt is made to give a unified picture of repeated loads information available through NACA studies. Three load sources and their effectiveness in producing repeated loads are considered as being of possible significance to any airplane. These types are gust, maneuver, and ground loads of airplanes of any type and their components. The discussion is restricted to the more general aspects of each loading and to NACA work. Since work in the field of repeated loads has been concentrated in the past on gust loads, the reader will find that the material is more extensive in regard to gust loads.

INVESTIGATIONS OF BRAKE SYSTEMS ON AUTOMOBILES. (Bremswerkuntersuchungen am Kraftfahrzeug). H. Klaue. May 1956. 68p. diagrs., photos., tabs. (Trans. from Deutsche Kraftfahrtforschung, no.13, 1938, p.1-26)

The decisive factor for utilization of the interlocking forces between wheel and road for the braking of automobiles is the friction coefficient, between brake lining and brake drum on one hand, between tire and road on the other. After detailed theoretical considerations, the brake coefficients utilizable in braking are represented as functions of the slip for various road conditions, and the friction coefficients between brake lining and brake drum are determined. The brake-force distribution and its influence on the attainable braking deceleration are investigated and a brake-force distributor for hydraulic brakes is examined particularly with respect to its locking-preventive effect.

REPRESENTATION OF THE FREE VIBRATIONS OF A WING IN THE WIND WITH THE AID OF THE CONCEPT OF MEMORY. (Représentation des vibrations libres d'une aile dans le vent á l'aide de la notion de la mémoire). R. Mazet. May 1956. 29p. diagrs. (Trans. of Office National d'Etudes et de Récherches Aéronautiques, Note Technique No. 19. 1954)

The free vibrations of a lifting surface in an aerodynamic medium resulting from an arbitrary initial impulse is the problem studied. It is of a certain interest for the determination of the critical speeds since these latter, by definition, separate the case where the free vibration until failure occurs. The object of the note is to show the advantage which one may derive, with regard to a solution of the problem, from the approximate method (the so-called generalized method). It is known that this half-theoretical, half-generalized method has already been successfully applied to the practical study of the behavior of physical systems around their states of equilibrium.

NACA RM A50H09

THE USE OF AREA SUCTION FOR THE PURPOSE OF DELAYING SEPARATION OF AIR FLOW AT THE LEADING EDGE OF A 63° SWEPT-BACK WING. Woodrow L. Cook, Roy N. Griffin, Jr., and Gerald M. McCormack. November 22, 1950. 68p. diagrs., photo., tab. (NACA RM A50H09)

An investigation was conducted to determine the effectiveness of area suction used to delay the separation of air flow at the leading edge of a 63° swept-back wing. The results obtained indicate that area suction was effective on a wing swept back 63° and increased the wing lift coefficient at which leading-edge air-flow separation first occurred from 0.25 to 0.67. The results also indicate that theory can be used to estimate the spanwise and chordwise extent of area suction necessary but the actual flow coefficient required in this preliminary investigation is considerably greater than that estimated by theory.

NACA RM A50K06

THE EFFECTS OF BOUNDARY-LAYER CONTROL ON THE LONGITUDINAL CHARACTERISTICS OF A SWEPT-BACK WING USING SUCTION THROUGH STREAMWISE SLOTS IN THE OUTBOARD PORTION OF THE WING. Gerald M. McCormack and William H. Tolhurst, Jr. January 5, 1951. 34p. diagrs., photo., tabs. (NACA RM A50K06)

The results are presented of an investigation to determine whether the aerodynamic characteristics of sweptback wings could be improved at lift coefficients below the maximum by the application of suction to short streamwise slots in the forward part of the outboard portion of the wing. The application of boundary-layer control in this simplified form to a 63° sweptback wing delayed the occurrence of detrimental effects of separation from an angle of attack of 8.5° to an angle of attack of 14°. Within this range separation was eliminated and the longitudinal characteristics of the wing were improved. Beyond this range separation occurred inboard of the slots and nullified the effects of boundary-layer control.

NACA RM A51G24

EXPERIMENTAL AND THEORETICAL STUDY OF THE EFFECTS OF BODY SIZE ON THE AERODYNAMIC CHARACTERISTICS OF AN ASPECT RATIO 3.0 WING-BODY COMBINATION. Edward J. Hopkins and Hubert C. Carel. October 1951. 52p. diagrs., photos., tabs. (NACA RM A51G24)

Measurements of the forces and moments were made for a wing (aspect ratio 3.0), for three geometrically similar bodies of revolution (fineness ratio 12.5), for the wing in the presence of each of the bodies, and for the wing combined with each of the bodies. The ratios of body diameter to wing span were 0.196, 0.259, and 0.343. Good agreement between the experimental and calculated results was obtained by including the velocities induced by the body on the wing and the velocities induced by the wing on the body in the theoretical analyses.

NACA RM A51J24

THE USE OF AREA SUCTION FOR THE PURPOSE OF DELAYING SEPARATION OF AIR FLOW AT THE LEADING EDGE OF A 63° SWEPT-BACK WING - EFFECTS OF CONTROLLING THE CHORDWISE DISTRIBUTION OF SUCTION-AIR VELOCITIES. Woodrow L. Cook and Mark W. Kelly. January 1952. 51p. diagrs., photo., tab. (NACA RM A51J24)

The results obtained from the investigation of area suction applied to a 63° sweptback wing with an NACA 64A006 section parallel to the plane of symmetry indicate that area suction is effective in preventing leading-edge air-flow separation with the chordwise distributions of suction-air velocities controlled to be equal at all chordwise points. The occurrence of separation was delayed from a lift coefficient of 0.25 to a lift coefficient of 0.77 with a flow coefficient of 0.0034. The results also indicate that area suction was effective when applied with a trailing-edge flap deflected 45°.

NACA RM A52G02

AN INVESTIGATION AT SUBSONIC SPEEDS OF THE ROLLING EFFECTIVENESS OF A SMALL PERFORATED SPOILER ON A WING HAVING 45° OF SWEEPBACK. Angelo Bandettini. September 1952. 37p. diagrs., photos. (NACA RM A52G02)

The report presents the results of an investigation over a Mach number range of 0.25 to 0.96 and at a Reynolds number of 1,500,000 to determine the rolling effectiveness of a partial-span, perforated spoiler. Data were also obtained to determine the influence of the spoiler on the lift coefficient, drag coefficient, and pitching-moment coefficient. The wing had 45° of sweepback of the leading edge, an aspect ratio of 3, and a taper ratio of 0.4. The thickness-chord ratio parallel to the plane of symmetry was 0.03. The spoiler had an average projection of 6.3 percent of the local wing chord and extended over 24.6 percent of the semispan. Rolling-moment data obtained over the Mach number range of the test were used in the prediction of rate of roll. Tests were also made at Reynolds numbers of 3,000,000 and 6,000,000 at a Mach number of 0.25.

NACA RM A52G07

THE EFFECTS OF OSCILLATION AMPLITUDE AND FREQUENCY ON THE EXPERIMENTAL DAMPING IN PITCH OF A TRIANGULAR WING HAVING AN ASPECT RATIO OF 4. Benjamin H. Beam. September 1952. 44p. diagrs., photo., tab. (NACA RM A52G07)

Results are presented of a wind-tunnel investigation of the variation of the damping-in-pitch parameter $C_{m_q} + C_{m_{\dot{\alpha}}}$ with Mach number, Reynolds number, angle of attack, oscillation frequency, oscillation amplitude, and pitching axis for a model triangular wing of aspect ratio 4 and NACA 0006-63 section combined with a slender, sharp-nosed body in the subsonic Mach number range. The results show a large effect of Reynolds number for certain test conditions and a region of dynamic instability at high subsonic Mach numbers.

NACA RM A54G14

EFFECT OF ROTATION OF AN NACA 1-SERIES E-TYPE COWLING ON THE INTERNAL FLOW AND FORCE CHARACTERISTICS OF THE COWLING AT MACH NUMBERS UP TO 0.84 AND AT AN ANGLE OF ATTACK OF 0°. Robert I. Sammonds and Robert M. Reynolds. October 1954. 54p. diagrs., photos., tabs. (NACA RM A54G14)

The pressure recovery and flow angle in the duct, the flow through the cowl gap, and the thrust and torque of an NACA E-type cowl without a propeller are presented for various inlet velocity and advance ratios. All tests were made at a Reynolds number of 1.72 million, based on the maximum diameter of the cowl.

NACA RM A54H09

EXPERIMENTAL AND PREDICTED LONGITUDINAL RESPONSE CHARACTERISTICS OF A LARGE FLEXIBLE 35° SWEPT-WING AIRPLANE AT AN ALTITUDE OF 35,000 FEET. Henry A. Cole, Jr., Stuart C. Brown, and Euclid C. Holleman. November 1954. 63p. diagrs., photo., tabs. (NACA RM A54H09)

Longitudinal dynamic response to elevator motions in the form of frequency response and transfer functions is presented for a large flexible swept-wing airplane over a range of Mach numbers and center-of-gravity locations at an altitude of 35,000 feet. Comparisons are made between predicted transfer functions for the rigid and flexible airplane, and experimental transfer functions evaluated from transient flight data.

NACA RM A54I21

A PRELIMINARY INVESTIGATION OF THE USE OF CIRCULATION CONTROL TO INCREASE THE LIFT OF A 45° SWEPTBACK WING BY SUCTION THROUGH TRAILING-EDGE SLOTS. Woodrow L. Cook, Roy N. Griffin, Jr., and David H. Hickey. December 1954. 56p. diagrs., photo., tabs. (NACA RM A54I21)

The effectiveness of circulation control for increasing lift on a 45° sweptback wing was investigated. Circulation control was accomplished by suction of air through slots at the trailing edge of the wing. The results indicate that appreciable increases in lift can be obtained without change in incidence on a sweptback wing.

NACA RM A55D14

THE EFFECTS OF FLEXIBILITY ON THE LONGITUDINAL AND LATERAL-DIRECTIONAL RESPONSE OF A LARGE AIRPLANE. Henry A. Cole, Jr., Stuart C. Brown, and Euclid C. Holleman. May 1955. 16p. diagrs. (NACA RM A55D14)

Longitudinal response to elevator control and lateral-directional response to aileron and rudder controls are presented in the form of frequency responses and transfer functions for a large flexible swept-wing airplane. Comparisons are made between predicted transfer function coefficients for the rigid and flexible airplane and those evaluated from transient flight data. Acceleration frequency responses to elevator motion for a number of locations on the airplane are compared with the calculated free-free normal modes of the airplane.

NACA RM A55J21

MEASUREMENT OF THE LONGITUDINAL MOMENT OF INERTIA OF A FLEXIBLE AIRPLANE. Henry A. Cole, Jr., and Frances L. Bennion. January 1956. 30p. diagrs., photos., tabs. (NACA RM A55J21)

A method for measuring the longitudinal moment of inertia of a flexible airplane by ground oscillation tests is presented. The effects of flexibility on the fundamental frequency for various combinations of springs and knife edges are shown, and a method which minimizes flexibility effects is developed. A description and results of tests which were conducted by this method are presented.

RELATION OF ENGINE TURBINE-BLADE LIFE TO STRESS-RUPTURE PROPERTIES OF THE ALLOYS, STELLITE 21, HASTELLOY B, CAST S-816, FORGED S-816, X-40, NIMONIC 80, REFRACTALOY 26, N-155, AND INCONEL X. F. B. Garrett and C. Yaker. August 1951. 59p. diagrs., photos., tabs. (NACA RM E51G13)

An investigation was conducted to relate the engine performance of the heat-resistant alloys, Stellite 21, Hastelloy B, cast S-816, forged S-816, X-40, Nimonic 80, Refractaloy 26, N-155, and Inconel X to their stress-rupture properties. The engine test consisted of the repetition of a 20-minute cycle, 15 minutes at rated speed and approximately 5 minutes at idle. The results of the investigation indicated a direct correlation between stress-rupture lift and blade life for the relatively low-strength alloys. The stress-rupture life and blade life for the relatively high-strength alloys did not correlate because of the effects of the vibratory stresses and the corrosive-gas atmosphere.

NACA RM E52C24

EFFECT OF FUEL PROPERTIES ON CARBON DEPOSITION IN ATOMIZING AND PREVAPORIZING TURBOJET COMBUSTORS. Jerrold D. Wear and William P. Cook. June 1952. 21p. photos., diagrs., tabs. (NACA RM E52C24)

Carbon deposition of various fuels obtained in fuel-prevaporizing and fuel-atomizing single tubular combustors was evaluated by smoking tendency, NACA K factor, and function of smoking tendency and volumetric average boiling temperature. The independent effects of change in sulfur, gum, and olefins on

carbon deposition were determined in either or both combustors. NACA K factor and smoking tendency were equally effective in relating carbon deposition from prevaporizing and atomizing combustors. The function of smoking tendency and volumetric average boiling temperature best related the carbon-deposition data obtained in prevaporizing combustor. Increases in sulfur conteht of two or three times and gum content of at least five times the maximum allowed by specification MIL-F-5624A would probably be possible before appreciable increase in carbon deposition would be obtained. Large increases in olefin content had no effect on carbon deposition.

NACA RM E52G07

TEMPERATURE RESPONSE OF TURBINE-BLADE METAL COVERED WITH OXIDE COATINGS SUPPLIED BY FUEL ADDITIVES. Richard J. McCafferty and Helmut F. Butze. August 1952. 20p. diagrs., photos., tab. (NACA RM E52G07)

The effects of turbine-blade oxide coatings, supplied by tetraethyl orthosilicate (producing silicon dioxide) and triamyl borate (producing boric oxide) used as fuel additives, on heat transfer from combustor-exhaust gases in the temperature range of 1400° to 2000° F to an S-816 alloy blade were determined. Results showed that the fuel additives provided that an oxide coating on all metal parts exposed to the exhaust gas and that the coating formed had no measurable effect on blade temperature at either static or transient exhaust-gas temperature conditions.

ANALYTICAL PROCEDURES FOR RAPID SELECTION OF COOLANT PASSAGE CONFIGURATIONS FOR AIR-COOLED TURBINE ROTOR BLADES AND FOR EVALUATION OF HEAT-TRANSFER, STRENGTH, AND PRESSURE-LOSS CHARACTERISTICS. Robert R. Ziemer and Henry O. Slone. September 1952. 53p. diagrs., tabs. (NACA RM E52G18)

A method based on geometric factors of the coolant passage was evolved for the rapid selection and evaluation of coolant passage configurations for air-cooled turbine rotor blades. The more promising coolant passage configurations, as selected by the simple blade evaluation criteria, are then analyzed by detailed methods to obtain absolute values of the required cooling-air weight flow, the pressure loss, and the strength characteristics. As a verification of the simple criteria, a comparison was made of three configurations for an air-cooled blade designed for use in a centrifugal-flow-compressor turbojet engine using both the simple criteria and detailed analytical methods. Analytical and experimental blade temperatures for two different coolant passage configurations of a blade used in a turbojet engine with a centrifugal compressor were compared. The simple criteria and the detailed analytical methods were used to select a coolant passage configuration for a turbine blade to be used in a turbojet engine having an axial-flow compressor.

NACA RM E53E14

EFFECT OF CERTAIN COMBINATIONS OF WALL CONTOURING AND DESIGN EXIT VELOCITY DISTRIBUTION ON PREDICTION OF TURBINE-NOZZLE MASS FLOW. Warner L. Stewart, Warren J. Whitney, and Thomas R. Heaton. July 1953. 17p. diagrs., tab. (NACA RM E53E14)

An investigation was conducted to determine if certain combinations of design nozzle-exit velocity distribution and wall contouring, employed to increase annulus area, can alter the three-dimensional flow characteristics such that nozzle mass flow cannot be predicted by ordinary two-dimensional design techniques. Four nozzle configurations with different wall contours and velocity distributions were analyzed in the axial-radial plane (axial symmetry was assumed) to determine the effect of the three-dimensional flow characteristics on the maximum mass flow. The accuracy of the method of analysis was established by comparing the maximum mass flow obtained by analysis with the maximum obtained experimentally. The results of the analysis indicated that two-dimensional design techniques were inadequate for use in predicting mass flow for the nozzle configuration designed for a nontwisted rotor and having a convex inswept inner wall. It was therefore concluded that certain combinations of nozzle-exit velocity distribution and wall contouring employed to vary annulus area can alter the three-dimensional flow characteristics to a point where two-dimensional design techniques are inadequate for predicting mass flow. Consideration of the three-dimensional flow characteristics must therefore be included in the design of nozzles to insure satisfactory turbine performance.

NACA RM L50G12

INVESTIGATION OF DOWNWASH, SIDEWASH, AND MACH NUMBER DISTRIBUTION BEHIND A RECTANGULAR WING AT A MACH NUMBER OF 2.41. D. Adamson and William B. Boatright. September 14, 1950. 115p. diagrs., photos., tab. (NACA RM L50G12)

An investigation of the nature of the flow field behind a rectangular circular-arc wing at a Mach number of 2.41 has been made. Pitot- and static-pressure measurements in the flow field behind the wing and detailed pitot surveys throughout the viscous wake were made. The flow direction was measured by means of a weathercocking vane. Theoretical calculations of both sidewash and downwash using Lagerstrom's superposition method have been made and are compared with experiment. Modifications, where they are necessary to bring about better agreement between theory and experiment, are shown and discussed. These include the effect of the finite thickness of the wing and the displacement of the vortex sheet.

NACA RM L51G06

DAMPING IN ROLL OF ROCKET-POWERED TEST VEHICLES HAVING SWEPT, TAPERED WINGS OF LOW ASPECT RATIO. E. Claude Sanders, Jr., and James L. Edmondson. October 1951. 25p. diagrs., photos., tab. (NACA RM L51G06)

Rocket-powered test vehicles were utilized to determine the damping in roll of a group of swept, tapered wings designed for flight in the transonic speed region. The Mach number range of the tests was from approximately 0.7 to 1.4.

NACA RM L51G11

PRELIMINARY INVESTIGATION OF A SUPERSONIC SCOOP INLET DERIVED FROM A CONICAL-SPIKE NOSE INLET. Charles E. Witliff and Robert W. Byrne. September 1951. 25p. diagrs., photos. (NACA RM L51G11)

A preliminary investigation has been conducted on a supersonic scoop inlet derived from a conical-spike nose inlet at Mach numbers of 1.3, 1.6, and 1.9. The influence of the boundary layer ahead of the inlet on the pressure recovery has been investigated. The pressure recovery has been measured for various boundary-layer suction-slot heights and various amounts of suction applied to the slot.

NACA RM L51G18

FLIGHT INVESTIGATION AT SUBSONIC, TRANSONIC, AND SUPERSONIC VELOCITIES OF THE HINGE-MOMENT CHARACTERISTICS, LATERAL-CONTROL EFFECTIVENESS, AND WING DAMPING IN ROLL OF A 60° SWEPTBACK DELTA WING WITH HALF-DELTA TIP AILERONS. (Revised.) C. William Martz and James D. Church. September 1951. 32p. diagrs., photos. (NACA RM L51G18)

Hinge-moment coefficients, damping-in-roll coefficients, aileron rolling-moment coefficients, and lateral-control effectiveness were obtained at zero angle of attack from a free-flight rocket-model test of a 60° sweptback half-delta wing-tip aileron mounted on a 60° sweptback delta wing. The wings were mounted on a pointed cylindrical body and tested over a Mach number range of 0.69 to 1.52 at aileron deflections from -5° to 5°. Comparisons are made with linearized theory and previous rocket-test results.

NACA RM L51K15

THE EFFECTS OF SUCTION THROUGH POROUS LEADING-EDGE SURFACES ON THE AERODYNAMIC CHARACTERISTICS OF A 47.5° SWEPTBACK WING-FUSELAGE COMBINATION AT A REYNOLDS NUMBER OF 4.4 x 10^6. Jerome Pasamanick and William I. Scallion. March 1952. 61p. diagrs., photo., tabs. (NACA RM L51K15)

Results of the investigation in the Langley full-scale tunnel of suction through porous leading-edge surfaces on a wing-fuselage configuration having 47.5° leading-edge sweep are presented. The wing aspect ratio was 3.4; the taper ratio was 0.51; and the airfoil sections normal to the quarter-chord line were NACA 64_1A112. The data include the effects of varying the chordwise and spanwise extent of suction and suction-flow quantities on the force, surface-pressure distribution, and internal flow measurements at zero yaw over a range of angle of attack. The Reynolds number of the tests was 4.4 x 10^6 and corresponds to a Mach number of approximately 0.07.

NACA RM L52D16

A SUMMARY AND ANALYSIS OF THE LOW-SPEED LONGITUDINAL CHARACTERISTICS OF SWEPT WINGS AT HIGH REYNOLDS NUMBER. G. Chester Furlong and James G. McHugh. August 1952. ii, 227p. diagrs., tabs. (NACA RM L52D16)

An analysis of the longitudinal characteristics of swept wings which is based on available large-scale low-speed data and supplemented with low-scale data when feasible is presented. The emphasis has been placed on the differentiation of the characteristics by a differentiation between the basic flow phenomenon involved. Insofar as possible all large-scale data available as of August 15, 1951 have been summarized in tabular form for ready reference.

NACA RM L52G11a

WIND-TUNNEL INVESTIGATION OF THE STATIC LATERAL STABILITY CHARACTERISTICS OF WING-FUSELAGE COMBINATIONS AT HIGH SUBSONIC SPEEDS. SWEEP SERIES. Richard E. Kuhn and Paul G. Fournier. September 1952. 30p. diagrs., photos. (NACA RM L52G11a)

This report presents the aerodynamic characteristics in sideslip of wing-fuselage combinations and of the fuselage alone. The wings have an aspect ratio of 4, taper ratio of 0.6, sweep angles from 3.6° to 60° at the quarter-chord line, and a 65A006 airfoil section. The tests covered a Reynolds number range from 2 million to 3.5 million, a Mach number range from 0.4 to 0.95, and an angle-of-attack range from -3° to 24°.

NACA RM L52G17

INVESTIGATION AT A MACH NUMBER OF 1.2 OF TWO 45° SWEPTBACK WINGS UTILIZING NACA 2-006 AND NACA 65A006 AIRFOIL SECTIONS. Homer B. Wilson, Jr. September 1952. 20p. diagrs., photo., tab. (NACA RM L52G17)

An investigation has been made to determine the lift, drag, and moment characteristics of a wing employing an airfoil section designed for high maximum lift at low speed (NACA 2-006) and having 45° sweepback, aspect ratio 4, and taper ratio 0.6. A similar wing with the NACA 65A006 airfoil section was also investigated to provide comparative data. The investigation was made at a Mach number of 1.2 and Reynolds numbers of 1.0 x 10^6 and 3.0 x 10^6 or 3.5 x 10^6. The gains at low speed associated with the use of the NACA 2-006 section can be obtained without penalty at Mach numbers of the order of 1.2, at least for the type of wing plan form considered in the present investigation.

NACA RM L52G18a

AERODYNAMIC LOAD MEASUREMENTS OVER A LEADING-EDGE SLAT ON A 40° SWEPTBACK WING AT MACH NUMBERS FROM 0.10 TO 0.91. Jones F. Cahill and Robert J. Nuber. September 1952. 32p. diagrs., photos., tab. (NACA RM L52G18a)

Data are presented showing the aerodynamic loads on a partial-span leading-edge slat on a 40° sweptback wing having NACA 64_1-112 airfoil sections perpendicular to the 0.273-chord line at Mach numbers from 0.10 to 0.91. Loads for the slat-retracted configuration were obtained from surface pressure measurements, and for the slat-extended condition from strain-gage balance readings. Slat load data cover a range of attack from zero lift to nearly maximum lift.

NACA RM L52L17

NACA 65-SERIES COMPRESSOR ROTOR PERFORMANCE WITH VARYING ANNULUS-AREA RATIO, SOLIDITY, BLADE ANGLE, AND REYNOLDS NUMBER AND COMPARISON WITH CASCADE RESULTS. Wallace M. Schulze, John R. Erwin, and George C. Ashby, Jr. February 1953. 62p. diagrs., photos., tab. (NACA RM L52L17)

An axial-flow compressor rotor was tested at low speed and without guide vanes or stators in a 28-inch test compressor. The rotor was designed for a free-vortex type blade loading using NACA 65-series 10-percent-thick airfoil sections. In these tests, the effects of changes of blade-setting angle, annulus area ratio, solidity and Reynolds number on rotor performance were determined for a range of quantity flows. Rotor data are compared with estimations based on uncorrected and corrected cascade data.

NACA RM L53A09a

INVESTIGATION OF THE EFFECTS OF LEADING-EDGE CHORD-EXTENSIONS AND FENCES IN COMBINATION WITH LEADING-EDGE FLAPS ON THE AERODYNAMIC CHARACTERISTICS AT MACH NUMBERS FROM 0.40 TO 0.93 OF A 45° SWEPTBACK WING OF ASPECT RATIO 4. Kenneth P. Spreemann and William J. Alford, Jr. February 1953. 46p. diagrs., photo., tabs. (NACA RM L53A09a)

An investigation was conducted in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.40 to 0.93 to determine the effects of a number of wing leading-edge modifications and fences on the aerodynamic characteristics in pitch of a wing-fuselage combination with the wing quarter-chord line swept back 45°, aspect ratio 4.0, taper ratio 0.3, and an NACA 65A006 airfoil section. Lift, drag, and pitching moment were obtained for all configurations over an angle-of-attack range of about -2° to 24°.

NACA RM L53G06

RESULTS OF MEASUREMENTS OF MAXIMUM LIFT AND BUFFETING INTENSITIES OBTAINED DURING FLIGHT INVESTIGATION OF THE NORTHROP X-4 RESEARCH AIRPLANE. Thomas F. Baker. August 1953. 22p. diagrs., photos., tab. (NACA RM L53G06)

The variation of the intensity of buffeting experienced throughout the operational region of the semitailless Northrop X-4 airplane and the values of maximum and peak normal-force coefficients in the Mach number range from 0.42 to 0.92 have been determined. The results are compared with data obtained with the swept-wing Douglas D-558-II airplane.

NACA RM L53G06a

MEASUREMENTS OF FLUCTUATING PRESSURES ON THE WINGS AND BODY OF A SWEPTBACK WING-BODY COMBINATION IN THE LANGLEY 16-FOOT TRANSONIC TUNNEL. Louis W. Habel and Donald R. Bowman. September 1953. 24p. diagrs., photos. (NACA RM L53G06a)

Results are presented from tests to determine the pressure fluctuations at eight locations on the body and one location on each wing of a sweptback wing-body combination in the Langley 16-foot transonic tunnel. Four model configurations were tested: the basic configuration, the wing-aft configuration for which the wing was effectively shifted about one wing root chord towards the rear of the body, a wing-leading-edge chord-extension configuration, and a wing leading-edge slat configuration.

NACA RM L53G09

STATIC LATERAL STABILITY CHARACTERISTICS OF AN AIRPLANE MODEL HAVING A 47.7° SWEPTBACK WING OF ASPECT RATIO 6 AND THE CONTRIBUTION OF VARIOUS MODEL COMPONENTS AT A REYNOLDS NUMBER OF 4.45×10^6. Roland F. Griner. September 1953. 83p. diagrs., photos., tabs. (NACA RM L53G09)

Presented herein are the results of an investigation conducted in the Langley 19-foot pressure tunnel to determine the low-speed characteristics in yaw of an airplane model and of the model main components at a Reynolds number of 4.45×10^6. The angle-of-yaw and angle-of-attack range are -10° to 29° and -2° to 30°, respectively. Limited studies of scale effect and of the effects of leading-edge flaps, fences, and double-slotted flaps are included. Emphasis is placed on the effectiveness of the sweptback vertical tail, the importance of tail length, and on the effective air flow at the vertical tail behind a fuselage or a midwing-fuselage combination having a 47.7° sweptback wing. Included are limited sidewash-angle and dynamic-pressure-ratio data from airflow surveys in the vicinity of a vertical-tail location behind the wing without the fuselage, the fuselage alone, and the wing-fuselage combination.

NACA RM L53G09a

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE STATIC LONGITUDINAL AND STATIC LATERAL STABILITY CHARACTERISTICS OF A WING-FUSELAGE COMBINATION HAVING A TRIANGULAR WING OF ASPECT RATIO 2.31 AND AN NACA 65A003 AIRFOIL. James W. Wiggins. August 1953. 28p. diagrs., photos. (NACA RM L53G09a)

This paper presents results of an investigation to determine the static longitudinal and static lateral stability characteristics of a wing-fuselage configuration with a delta wing having a leading-edge sweep of 60°, aspect ratio of 2.31, and an NACA 65A003 airfoil section parallel to the fuselage center line. A limited investigation was made to determine the effects of notches in the leading edge of the wing on the static longitudinal stability characteristics.

NACA RM L53G09b

LOW-SPEED INVESTIGATION OF THE AERODYNAMIC, CONTROL, AND HINGE-MOMENT CHARACTERISTICS IN SIDESLIP OF A DELTA-WING-FUSELAGE MODEL WITH HORN-BALANCE-TYPE AILERONS AND WITH AND WITHOUT NACELLES. William I. Scallion. August 1953. 31p. diagrs., photo., tabs. (NACA RM L53G09b)

Results are presented of an investigation to determine the low-speed aerodynamic, control, and control hinge-moment characteristics in sideslip of a 60° sweptback-delta-wing—fuselage combination with horn-balance-type ailerons of 10.2 percent total wing area. The airfoil section was NACA 65A003 and the aspect ratio was 2.31. The model was tested with and without chord-plane nacelles at several angles of attack and sideslip. The Reynolds number was 2.3×10^6 and the Mach number was 0.10.

NACA RM L53G10b

SOME FLUTTER EXPERIMENTS AT A MACH NUMBER OF 1.3 ON CANTILEVER WINGS WITH TUBULAR AND CLOSED BODIES AT THE TIPS. John Locke McCarty and W. J. Tuovila. October 1953. 17p. diagrs., tab. (NACA RM L53G10b)

Flutter tests of 39 cantilever wings with tubular bodies or closed bodies at the tips have been made in a small intermittent-flow supersonic wind tunnel where the testing technique involved changing the structural parameters so that the combinations would flutter at the tunnel Mach number of 1.3. The experimental results are compared with an analysis that uses two-dimensional supersonic air forces on the wing and tube forces derived from a modified slender body theory. The effects of some parameters on the flutter-speed coefficient are determined from the experimental results.

NACA RM L53G13

INVESTIGATION OF THE EFFECTS OF LEADING-EDGE FLAPS ON THE AERODYNAMIC CHARACTERISTICS IN PITCH AT MACH NUMBERS FROM 0.40 TO 0.93 OF A WING-FUSELAGE CONFIGURATION WITH A 45° SWEPTBACK WING OF ASPECT RATIO 4. Kenneth P. Spreemann and William J. Alford, Jr. August 1953. 36p. diagrs., photo., tabs. (NACA RM L53G13)

An investigation was conducted in the Langley high-speed 7- by 10-foot tunnel over a Mach number range of 0.40 to 0.93 to determine the effects of full-span and various partial-span combinations of leading-edge flaps on the aerodynamic characteristics in pitch of a wing-fuselage combination with the wing quarter-chord line swept back 45°, aspect ratio 4.0, taper ratio 0.3, and an NACA 65A006 airfoil section. Lift, drag, and pitching moments were obtained for all configurations over an angle-of-attack range of about -2° to 24°.

NACA RM L53G14a

WIND-TUNNEL INVESTIGATION OF THE AERODYNAMIC CHARACTERISTICS IN PITCH AND SIDESLIP AT HIGH SUBSONIC SPEEDS OF A WING-FUSELAGE COMBINATION HAVING A TRIANGULAR WING OF ASPECT RATIO 4. Paul G. Fournier. August 1953. 23p. diagrs., photos. (NACA RM L53G14a)

This report presents the aerodynamic characteristics in pitch and sideslip at high subsonic speeds of a wing-fuselage combination having a triangular wing of aspect ratio 4, a leading-edge sweep angle of 45°, and with an NACA 65A006 airfoil section parallel to the plane of symmetry. The tests covered a range of Mach number from 0.40 to 0.95, a range of Reynolds number from 2.4×10^6 to 3.9×10^6, and a range of angle of attack from -3° to 24°.

NACA RM L53G21

AN ANALYTICAL STUDY OF SIDESLIP ANGLES AND VERTICAL-TAIL LOADS IN ROLLING PULLOUTS AS AFFECTED BY SOME CHARACTERISTICS OF MODERN HIGH-SPEED AIRPLANE CONFIGURATIONS. Ralph W. Stone, Jr. October 1953. 41p. diagrs., tabs. (NACA RM L53G21)

This paper presents the results of an analytic study of the variations of angle of sideslip in rolling-pullout maneuvers. The effects of variations in yawing-moment stability derivatives and possible errors in these derivatives on sideslip angle are discussed, as are the effects of oscillations in the vertical-tail load.

NACA RM L53G22

FLIGHT MEASUREMENT OF AERODYNAMIC LOADS AND MOMENTS ON AN EXTERNAL STORE MOUNTED UNDER THE WING OF A SWEPT-WING FIGHTER-TYPE AIRPLANE. Thomas C. O'Bryan. November 1953. 25p. diagrs., photo., tab. (NACA RM L53G22)

Flight measurements of external store characteristics have been obtained using a 245-gallon external fuel tank mounted under the wing of a North American F-86A airplane. The external-store normal- and side-load distributions were measured,

by means of an integrating pressure system, at three Mach numbers (M = 0.55, 0.75, and 0.83) for a range of lift coefficients up to the attainment of heavy buffeting. The results are presented in the form of load-coefficient distributions and their corresponding overall force and moment coefficients.

NACA RM L53G29a

DAMPING-IN-PITCH CHARACTERISTICS AT HIGH SUBSONIC AND TRANSONIC SPEEDS OF FOUR 35° SWEPTBACK WINGS. William B. Kemp, Jr., and Robert E. Becht. October 1953. 21p. diagrs., tab. (NACA RM L53G29a)

Free-oscillation tests in pitch have been conducted on four semispan-wing models having an aspect ratio of 3.0, a taper ratio of 0.6, and 35° sweepback of the quarter-chord line. Thickness ratios of 6 percent and 10.5 percent were investigated and two model sizes were used giving maximum Reynolds numbers of about 0.5×10^6 and 4×10^6 at maximum Mach numbers of 1.05 and 0.97, respectively. The effects of leading-edge roughness were determined for each model.

NACA RM L53G31

A PRELIMINARY STUDY BY MEANS OF ELECTRICAL FREQUENCY-ANALYSIS TECHNIQUES OF THE RESPONSE OF AN AIRPLANE STRUCTURE DURING BUFFETING. John E. Yeates, Jr., and Jim Rogers Thompson. December 1953. 41p. diagrs., tab. (NACA RM L53G31)

A study of flight buffeting records was made utilizing electrical frequency analysis techniques in order to investigate in detail the response of an airplane structure during buffeting. It was found that buffeting response occurred principally at the lower natural frequencies of the structure; that the relative amplitude of different modes varied with flight condition; and the response in each mode was not steady but consisted of a series of bursts at random time intervals.

NACA RM L53L23

EXPERIMENTAL INFLUENCE COEFFICIENTS FOR THE DEFLECTION OF THE WING OF A FULL-SCALE, SWEPT-WING BOMBER. Alton P. Mayo and John F. Ward. April 1954. 25p. diagrs., tabs. (NACA RM L53L23)

The results of deflection measurements on the wing of a swept-wing, jet bomber airplane are presented in the form of structural influence coefficients relating the deflection of a system of points on the wing to point loads applied on the wing spars. The procedures used for obtaining the coefficients are presented along with a comparison of wing deflections calculated with experimental influence coefficients and those measured in the manufacturers static proof test. Also presented are curves of wing twist in the streamwise direction due to point loads applied along the wing one-quarter-chord line.

NACA RM L54G01

EXPERIMENTAL INVESTIGATION OF THE FORCES AND MOMENTS DUE TO SIDESLIP OF A SERIES OF TRIANGULAR VERTICAL- AND HORIZONTAL-TAIL COMBINATIONS AT MACH NUMBERS OF 1.62, 1.93, AND 2.41. Donald E. Coletti. August 1954. 32p. diagrs., photo., tabs. (NACA RM L54G01)

An experimental investigation was made at Mach numbers of 1.62, 1.93, and 2.41 of the sideslip derivatives for tail arrangements consisting of a triangular vertical tail attached symmetrically to a triangular horizontal tail. Comparisons are made with the theoretical derivatives presented in NACA TN 3071 and NACA TN 2412.

NACA RM L54G09a

A FLIGHT STUDY OF COMPRESSIBILITY EFFECTS ON THE GUST LOADS OF A 35° SWEPTBACK-WING AIRPLANE. Harry C. Mickleboro and Jack Funk. August 1954. 23p. diagrs., tabs. (NACA RM L54G09a)

A swept-wing airplane was flown at different speeds in rough air to investigate the effects of compressibility or Mach number on gust loads. Data were obtained at a constant altitude over a Mach number range from 0.4 to 0.85. For the test airplane, the measured gust loads increased more rapidly than a direct (one to one) variation with forward speed. The experimental results for the variation of loads with Mach number for the airplane without external tanks were in agreement with calculations based on lift-curve slopes corrected for compressibility and two-dimensional unsteady-lift functions for compressible flow. The addition of external tanks caused a more rapid increase in gust loads with Mach number for the test airplane.

NACA RM L54G12

SOME EFFECTS OF TAIL HEIGHT AND WING PLAN FORM ON THE STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A SMALL-SCALE MODEL AT HIGH SUBSONIC SPEEDS. Albert G. Few, Jr., and Thomas J. King, Jr. August 1954. 63p. diagrs., photo. (NACA RM L54G12)

The present paper presents some effects of horizontal tail height and wing plan form on the static longitudinal characteristics of a complete model at high subsonic speeds. All wings had an aspect ratio of 3, quarter-chord sweeps of 25°, 30°, and 35°, and NACA 65A004 airfoil sections parallel to free stream. The Mach number range extended from about 0.80 to 0.94 with corresponding Reynolds numbers ranging from about 1.17×10^6 to 1.29×10^6.

NACA RM L54I02

CASCADE INVESTIGATION OF A RELATED SERIES OF 6-PERCENT-THICK GUIDE-VANE PROFILES AND DESIGN CHARTS. James C. Dunavant. November 1954. 48p. diagrs., tabs. (NACA RM L54I02)

A new guide-vane blade series for high critical speeds of improved section characteristics has been derived. Low-speed cascade tests were made of four blade sections of this series at solidities of 0.75, 1.00, and 1.50. From these tests, design angles of attack were selected and are presented as a method of determining camber for guide-vane turning angles as high as 50°. The results of a number of simple computations made to estimate the high-speed characteristics of the blade series are presented.

NACA RM L54L21

LOW-SPEED WIND-TUNNEL INVESTIGATION OF LEADING-EDGE POROUS SUCTION ON A 4-PERCENT-THICK 60° DELTA WING. E. Carson Yates, Jr. March 1955. 73p. diagrs., photo., tabs. (NACA RM L54L21)

A 60° delta-wing–fuselage model employing a 4-percent-thick airfoil section with large leading-edge radius was tested to determine the effectiveness of porous leading-edge suction in delaying and reducing leading-edge separation and the accompanying high drag. Mach numbers for the tests were between 0.06 and 0.20, and Reynolds numbers were between 5.8×10^6 and 17.4×10^6. Lift, drag, pitching moment, and leading-edge pressure-distribution data are given. Fences at the outboard end of the suction area and outboard droop-nose chord-extensions were tested on the delta wing. For some of the tests, the wing tips outboard of the suction area were removed. The resulting clipped wing was also tested with inboard and full-span split flaps.

NACA RM L55B17

FLIGHT TESTS OF A DELTA-WING VERTICALLY RISING AIRPLANE MODEL POWERED BY A DUCTED FAN. Powell M. Lovell, Jr. April 1955. 23p. diagrs., photos., tab. (NACA RM L55B17)

The results of a free-flight investigation of the stability and control characteristics of a delta-wing vertically rising airplane model powered by a ducted fan in take-offs, landings, and in hovering and forward flight are presented. Some effects of various artificial stabilizing devices were determined.

NACA RM L55E18a

INVESTIGATION OF EFFECT OF REDUCTION OF VALVE FRICTION IN A POWER CONTROL SYSTEM BY USE OF A VIBRATOR. William H. Phillips. July 1955. 11p. diagrs., photo. (NACA RM L55E18a)

Brief ground tests were made to determine the effect of reduction of valve friction in a power control system of a fighter airplane by use of a vibrator. The vibrator was found to be an effective means of overcoming adverse effects of valve friction on the control characteristics.

NACA RM L55J05

LOW-SPEED CASCADE INVESTIGATION OF LOADED LEADING-EDGE COMPRESSOR BLADES. James C. Emery. January 1956. 76p. diagrs., photo., tabs. (NACA RM L55J05)

Loaded leading-edge compressor-blade sections have been investigated systematically in cascade at low speed. Blade cambers having isolated-airfoil lift coefficients of 0.6, 1.2, 1.8, and 2.4 were tested over the usable angle-of-attack range for inlet-air angles of 30°, 45°, and 60° at solidities of 1.0 and 1.5. A comparative evaluation has been made of the results of this and previous cascade investigations of compressor blades having uniform chordwise loading as isolated airfoils and those having more loading at the trailing edge.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1246

THE HYDRODYNAMIC CHARACTERISTICS OF MODIFIED RECTANGULAR FLAT PLATES HAVING ASPECT RATIOS OF 1.00, 0.25, AND 0.125 AND OPERATING NEAR A FREE WATER SURFACE. Kenneth L. Wadlin, John A. Ramsen, and Victor L. Vaughan, Jr. 1955. ii, 50p. diagrs., photos. (NACA Rept. 1246. Supersedes TN 3079; TN 3249)

Results are presented from an investigation of the hydrodynamic forces and moments acting on modified rectangular flat plates with aspect ratios of 1.00, 0.25, and 0.125 mounted on a single strut and operating near the free water surface. A simplified method of obtaining the lift characteristics in unseparated flow at large depths is presented. The experimental effects of changing the angle of attack, depth of submersion, and aspect ratio are presented. The effects of cavitation and two types of high-angle leading-edge separation are also presented.

NACA Rept. 1248

AN EXPERIMENTAL STUDY OF APPLIED GROUND LOADS IN LANDING. Benjamin Milwitzky, Dean C. Lindquist, and Dexter M. Potter. 1955. ii, 34p. diagrs., photos., tab. (NACA Rept. 1248. Supersedes and extends TN 3246)

This report presents a study of the applied ground loads and the coefficient of friction during wheel spin-up in impacts of a small landing gear under controlled conditions on a concrete landing strip in the Langley impact basin. The basic investigation included impacts with forward speed, impacts with forward speed and reverse wheel rotation to simulate higher horizontal velocities, and spin-up drop tests. The effects of wheel prerotation to reduce the relative horizontal velocity were also investigated. An attempt has been made to interpret the experimental data so as to obtain an insight into the physical phenomena involved in the wheel spin-up process, particularly the factors which influence the magnitude and variation of the coefficient of friction between the tire and the ground.

NACA RM L56G10

MODEL DITCHING INVESTIGATION OF A JET TRANSPORT AIRPLANE WITH VARIOUS ENGINE INSTALLATIONS. William C. Thompson. August 1956. 27p. diagrs., photos., tabs. (NACA RM L56G10)

The ditching characteristics of a jet transport airplane with various engine configurations were investigated in Langley tank No. 2. A dynamic model was used to determine the probable ditching behavior in calm water and the best ditching procedure. Various conditions of damage, engine installations, landing attitude, and speed were investigated. Data were obtained from visual observations, acceleration records, and motion pictures.

NACA TM 1395

THE FATIGUE STRENGTH OF RIVETED JOINTS AND LUGS. (De vermoeiingssterkte van Klinkverbindingen en pengatverbindingen). J. Schijve. August 1956. 54p. diagrs., tabs. (NACA TM 1395. Trans. of Nationaal Luchtvaartlaboratorium, Rapport M.1952, May 1954)

This report deals with a number of tests on riveted joints and lugs for the primary purpose of comparing the several types of riveted joints and to study the effect of various factors on the fatigue strength of lugs. A check was made to ascertain whether or not an estimate of the fatigue life at a certain loading could be made from the dimensions of the joint and the fatigue data of the unnotched material. Recommendations are made on the proportioning of joints to obtain better fatigue behavior.

NACA TM 1423

SAFEGUARDS AGAINST FLUTTER OF AIRPLANES. (Précautions a prendre pour éviter les vibrations aérodynamiques des avions. I - Voilure. II - Empennages). Gerhard De Vries. August 1956. 94p. diagrs. (NACA TM 1423. Trans. from: La Recherche Aéronautique, no.12, 1949, p.15-30. La Recherche Aéronautique, no.13, 1950, p.27-43)

This report is a compilation of practical rules, derived both from theory and from experience, intended to guide the aeronautical engineer in the design of flutter-free airplanes. Rules applicable to the wing, the ailerons, the flaps, tabs, tail surfaces, and fuselage are discussed. Five appendixes are included.

NACA TN 3273

COMPRESSIBILITY FACTOR, DENSITY, SPECIFIC HEAT, ENTHALPY, ENTROPY, FREE-ENERGY FUNCTION, VISCOSITY, AND THERMAL CONDUCTIVITY OF STEAM. Lilla Fano, John H. Hubbell, and Charles W. Beckett, National Bureau of Standards. August 1956. 61p. diagrs., tabs. (NACA TN 3273)

The NBS-NACA tables of thermal properties of steam are grouped together for convenient use. They include the compressibility factor, density, specific heat at constant pressure, enthalpy, entropy, free-energy function, viscosity, and thermal conductivity for the real gas and the specific heat, enthalpy, entropy, and free-energy function for the ideal gas. Conversion factors to frequently used units are given to facilitate use of the tables in dimensionless form.

NACA TN 3276

PROPERTIES OF AIRCRAFT FUELS. Henry C. Barnett and Robert R. Hibbard. August 1956. 152p. diagrs., tabs. (NACA TN 3276. Supersedes RM E53A21; RM E53I16)

The primary objective of this report is to collect fuel data that should aid in the design of aircraft fuel systems. It includes a survey of recent production jet fuels and shows the ranges of fuel properties which can be encountered for each grade of fuel. The effect of temperature and pressure on many of these properties is given. In the future fuel oils may be used in jet aircraft; and, therefore, these fuels have also been treated. In addition there are discussions on the development of jet fuel specifications and the pertinence of fuel properties to fuel-system design. The practical problems associated with the use of aircraft fuels are also discussed.

NACA TN 3278

ATTENUATION IN A SHOCK TUBE DUE TO UNSTEADY-BOUNDARY-LAYER ACTION. Harold Mirels. August 1956. 60p. diagrs. (NACA TN 3278)

A method is presented for obtaining the attenuation of a shock wave in a shock tube due to the unsteady boundary layer along the shock-tube walls. It is assumed that the boundary layer is thin relative to the tube diameter and induces one-dimensional longitudinal pressure waves whose strength is proportional to the vertical velocity at the edge of the boundary layer. The method is shown to be in reasonably good agreement with existing experimental data.

NACA TN 3656

A SELF-BALANCING LINE-REVERSAL PYROMETER. Donald Buchele. August 1956. 68p. diagrs., photos., tabs. (NACA TN 3656)

A self-balancing line-reversal pyrometer is described that measures gas temperatures from 2900° to 4500° R. Its two optical components are a reflector and a fully enclosed unit containing a projection lamp, spectroscope, and photoelectric detector of line reversal. An automatic balancing mechanism permits remote operation by semiskilled personnel. Local-temperature measurements can be made by injection of a narrow stream of sodium-containing powder into the gas from a probe upstream of the point of measurement. In a comparison with a thermocouple pyrometer and a pneumatic-probe pyrometer, the average deviation of the line-reversal method from the mean of all measurements was 60° R.

NACA TN 3694

METHOD FOR CALCULATING THE AERODYNAMIC LOADING ON AN OSCILLATING FINITE WING IN SUBSONIC AND SONIC FLOW. Harry L. Runyan and Donald S. Woolston. August 1956. 76p. diagrs., tabs. (NACA TN 3694)

A method is presented for calculating the loading on a finite wing oscillating in subsonic or sonic flow. The method is applicable to any plan form and may be used for determining the loading on deformed wings. The procedure is approximate and requires a numerical integration over the wing surface.

NACA TN 3723

CALCULATIONS OF THE FLOW OVER AN INCLINED FLAT PLATE AT FREE-STREAM MACH NUMBER 1. Walter G. Vincenti, Cleo B. Wagoner, and Newman H. Fisher, Jr. August 1956. 70p. diagrs., tabs. (NACA TN 3723)

A numerical solution is given of the complete equations of inviscid compressible flow for the case of an inclined flat plate at free-stream Mach number 1. The calculations are carried as far as the end of the separated region that appears on the upper surface of the plate near the leading edge. The results, which are for an angle of attack of 13°, show the pressure distribution on the lower surface and the detailed flow field about the lower surface and the leading edge.

NACA TN 3724

CHARACTERISTICS OF FOUR NOSE INLETS AS MEASURED AT MACH NUMBERS BETWEEN 1.4 AND 2.0. George B. Brajnikoff and Arthur W. Rogers. August 1956. 48p. diagrs., photos. (NACA TN 3724. Supersedes RM A51C12)

The performance characteristics of two open-nose and two conical-shock diffusers were measured at supersonic speeds between $M_0 = 1.4$ and 2.0 at angles of attack of 0°, 3°, 6°, and 9°. Schlieren photographs of flow about the models at 0° angle of attack were used to calculate external wave drag; these values of drag agreed well with those obtained by direct force measurements after addition of skin-friction drag, except in cases of reduced mass-flow ratios.

NACA TN 3726

COMPRESSIVE AND TORSIONAL BUCKLING OF THIN-WALL CYLINDERS IN YIELD REGION. George Gerard, New York University. August 1956. 42p. diagrs., tabs. (NACA TN 3726)

Based on assumptions which have led to the best agreement between theory and test data on inelastic buckling of flat plates, a general set of equilibrium differential equations for the plastic buckling of cylinders has been derived. These equations have been used to obtain solutions for the compressive and torsional buckling of long cylinders in the yield region. Test data are presented which indicate satisfactory agreement with the theoretical plasticity-reduction factors in most cases.

NACA TN 3727

INFLUENCE OF HOT-WORKING CONDITIONS ON HIGH-TEMPERATURE PROPERTIES OF A HEAT-RESISTANT ALLOY. John F. Ewing and J. W. Freeman, University of Michigan. August 1956. 134p. diagrs., photos., tabs. (NACA TN 3727)

A study was made to determine the influence of various hot-working conditions on the high-temperature properties of a heat-resistant alloy. The effects of hot-working on response to subsequent heat treatment were also studied. The working conditions varied were temperature, amount of reduction, and a combination of both. The evaluation of the effects of rolling was based on rupture and creep tests, hardness measurements, microstructural examination, and lattice-parameter measurements.

NACA TN 3728

STUDY OF ALUMINUM DEFORMATION BY ELECTRON MICROSCOPY. A. P. Young, C. W. Melton, and C. M. Schwartz, Battelle Memorial Institute. August 1956. 39p. diagrs., photos. (NACA TN 3728)

The slip-line structure in a series of aluminum single crystals at various stages during deformation was examined in an electron microscope. The slip-line structure was also investigated in crystals strained after various degrees of prestraining. On the basis of the data from this study and from other investigations a theory is proposed for the deformation mechanism in aluminum crystals. The possible effects of short-range ordering on deformation modes are discussed.

NACA TN 3729

MECHANICAL TESTS ON SPECIMENS FROM LARGE ALUMINUM-ALLOY FORGINGS. James A. Miller and Alfred L. Albert, National Bureau of Standards. August 1956. 25p. diagrs., photos., tabs. (NACA TN 3729)

Results of tensile and bend tests on specimens in the T6 condition from 12- by 12- by 24-inch hand forgings of 7075 (75S) and 2014 (14S) aluminum alloy are presented. Properties are given for specimens from various locations within the forgings as well as for specimens oriented in both the longitudinal and transverse directions.

NACA TN 3730

THE INTERFERENCE EFFECTS OF A BODY ON THE SPANWISE LOAD DISTRIBUTIONS OF TWO 45° SWEPTBACK WINGS OF ASPECT RATIO 8.02 FROM LOW-SPEED TESTS. Albert P. Martina. August 1956. 47p. diagrs., photo., tabs. (NACA TN 3730. Supersedes RM L51K23)

Tests of two wing-body combinations have been conducted in the Langley 19-foot pressure tunnel at a Reynolds number of 4×10^6 to determine the effects of the bodies on the wing span load distributions. The wings had aspect ratios of 8.02, taper ratios of 0.45, and incorporated 12-percent-thick airfoil sections streamwise. One wing was untwisted and uncambered; the second wing was twisted and cambered. Identical bodies of revolution of 10:1 fineness ratio were mounted in mid-high-wing positions. The effects of wing incidence, wing fences, and flaps were determined for the plane wing.

NACA TN 3733

PROBABILITY AND FREQUENCY CHARACTERISTICS OF SOME FLIGHT BUFFET LOADS. Wilber B. Huston and T. H. Skopinski. August 1956. 52p. diagrs., tabs. (NACA TN 3733)

The frequency characteristics and statistical properties of the buffet loads measured on the unswept wing and tail of a fighter airplane have been studied in the stall and in the shock regime. The results indicate that the wing loads in buffeting can be treated as the Gaussian response of a simple elastic system. The tail loads appear to represent a more complicated process.

NACA TN 3736

POISSON'S RATIOS AND VOLUME CHANGES FOR PLASTICALLY ORTHOTROPIC MATERIAL. Elbridge Z. Stowell and Richard A. Pride. August 1956. 28p. diagrs., photos. (NACA TN 3736)

Measurements of Poisson's ratios have been made in three orthogonal directions on aluminum-alloy blocks in compression and on stainless-steel sheet in both tension and compression. These measurements, as well as those obtained by density determinations, show that there is no permanent plastic change in volume within the accuracy of observation. A method is suggested whereby a correlation may be effected between the measured individual values of the Poisson's ratios and the stress-strain curves for the material. Allowance must be made for the difference in the stress-strain curves in tension and compression; this difference, wherever it appears, is accompanied by significant changes in the Poisson's ratios.

NACA TN 3738

THEORETICAL AND EXPERIMENTAL INVESTIGATION OF THE SUBSONIC-FLOW FIELDS BENEATH SWEPT AND UNSWEPT WINGS WITH TABLES OF VORTEX-INDUCED VELOCITIES. William J. Alford, Jr. August 1956. 91p. diagrs., photo., tabs. (NACA TN 3738)

The flow characteristics around swept and unswept wings necessary in first-order estimations of aerodynamic loadings, trajectories, and jettison characteristics of missiles, fuel tanks, or bombs as determined experimentally are compared with the flow fields as calculated by potential-flow theory. The theoretical predictions of the flow-field characteristics were qualitatively correct in all cases considered, although there were indications that the magnitude of the downwash angles tended to be overpredicted as the tip of the swept wing was approached and that the sidewash angles ahead of the swept wing were underpredicted.

NACA TN 3742

TENSILE PROPERTIES OF HK31XA-H24 MAGNESIUM-ALLOY SHEET UNDER RAPID-HEATING CONDITIONS AND CONSTANT ELEVATED TEMPERATURES. Thomas W. Gibbs. August 1956. 20p. diagrs., tabs. (NACA TN 3742)

Specimens of HK31XA-H24 magnesium-alloy sheet from an experimental batch were heated to failure at nominal temperature rates from 0.2° F to 100° F per second under constant-load conditions. Rapid-heating yield and rupture stresses are presented and compared with the yield and ultimate stresses from elevated-temperature tensile stress-strain tests for 1/2-hour exposure. Linear temperature-rate parameters were used to correlate rapid-heating results by constructing master curves which can be used for predicting yield stresses and temperatures and for estimating rupture stresses and temperatures.

NACA TN 3757

TORSIONAL INSTABILITY OF HINGED FLANGES STIFFENED BY LIPS AND BULBS. George Gerard, New York University. August 1956. 12p. diagrs. (NACA TN 3757)

Based on torsional instability theory, buckling charts are presented for determining the critical strain of hinged flanges stiffened by idealized lip and bulb elements.

NACA TN 3759

ANALYSIS OF LAMINAR INCOMPRESSIBLE FLOW IN SEMIPOROUS CHANNELS. Patrick L. Donoughe. August 1956. 25p. diagrs., tabs. (NACA TN 3759)

Perturbation solutions for laminar incompressible flow in semiporous and fully porous channels are compared. The perturbation parameter measures the amount of suction or blowing at the porous wall. The velocity profile and the wall friction parameter are more affected by suction or blowing for the semiporous channel than for the fully porous channel. For blowing through the wall, the pressure decreases in channel direction for both channels; with sufficiently high suction rates, the analysis showed that the pressure rises in flow direction for the fully porous channel.

NACA TN 3760

AERODYNAMIC MIXING DOWNSTREAM FROM LINE SOURCE OF HEAT IN HIGH-INTENSITY SOUND FIELD. William R. Mickelsen and Lionel V. Baldwin. August 1956. (ii), 75p. diagrs., photos. (NACA TN 3760)

Theory and measurement showed that the heat wake downstream from a line source is displaced by a transverse standing sound wave in a manner similar to a flag waving in a harmonic mode. With a 147 db, 104 cps standing wave, time-mean temperatures were reduced by an order of magnitude except near the displacement-pattern nodal points. The theory showed that a 161 db, 520 cps standing wave considerably increased the mixing in both the time-mean and instantaneous senses.

Aeronautical Research Council (Gt. Brit.)
AN INVESTIGATION OF HIGH ALTITUDE CRUISING CONDITIONS FOR TURBO-JET AIRCRAFT. R. T. Shields, J. Stephenson, and I. E. Utting. 1956. 35p. diagrs., tab. (ARC CP 215)

Specific air range has been measured on the Ashton MK.1 at high altitude using differing techniques. A "quasi-level" procedure consisting of runs at constant speed involving a small rate of climb or descent is recommended for performance measurements near the optimum range conditions and any speed below about m = 1.2. Optimum specific range for the Ashton is obtained at the theoretically predicted conditions for an aircraft cruising below its drag critical Mach number, that is, maximum rpm and m = 1.2; increase of air temperature reduces this specific air range by about 1-3/4 percent per 10° C. An appendix derives and discusses the conditions for maximum specific air range, the argument being extended to the case with compressibility drag effects.

National Gas Turbine Establishment (Gt. Brit.)
SOME FURTHER JET FLAP EXPERIMENTS.
N. A. Dimmock. May 1956. 70p. diagrs., photos., tabs. (NGTE Memo. M.255)

Results are given of tests on the same airfoil which was used for an earlier work and which had a 12-5 percent thick elliptical cross section with a narrow full-span jet slot. This time, however, the jet deflection is 58.1° from the chord line. In addition to the measurement of the forces and moments acting on the model, the flow pattern in the vicinity of the airfoil was revealed with smoke filaments and was recorded photographically. A comparison with the theory of the previous report is drawn where appropriate and additional support is given to the thrust hypothesis. A check on the effects of RN variation and of the addition of transition wires to the model confirmed the results of the previous experiments. The influence of ground proximity on lift, center of lift position and thrust was investigated and found to be substantial.

ALTERNATING PRESSURES AND BLADE STRESSES IN AN AXIAL-FLOW COMPRESSOR. J. R. Forshaw, H. Taylor, and R. Chaplin. 29p. diagrs., photos., tabs. (ARC R & M 2846; ARC 14,509. Supersedes NGTE R. 92)

An investigation has been made into the origin of the forces exciting vibration in an axial-flow compressor, and their magnitude relative to the calculated gas bending loads. The blade stresses resulting from these forces were measured, and a value obtained for the energy input to a blade when vibrating in the predominant modes under running conditions. The experimental data were obtained from pressure elements and strain gages fitted to the inlet guide vanes and first four stator-blade rows of an early compressor.

Aeronautical Research Council (Gt. Brit.)
PRELIMINARY LOW SPEED WIND TUNNEL TESTS ON FLAT PLATES AND AIR BRAKES: FLOW, VIBRATION AND BALANCE MEASUREMENTS.
R. Fail, T. B. Owen, and R. C. W. Eyre. 1956. 45p. diagrs., tabs. (ARC CP 251)

Flow measurements were made behind sharp edged flat plates (a) at 90° for various shapes, and (b) for a square plate over an incidence range. Measurements of velocity fluctuations were made for (b), showing that a regular shedding of turbulent eddies occurs for $\theta = 50°$ and over, but stops by 40°. Lift, drag, and pitching-moment increments were measured on a square plate mounted on (a) a long cylinder and (b) near the end of several shapes of rear fuselage, to see how the moments on opening the brake could be modified. Comparative tests were made on a cascade brake.

RELATIVE ACCURACY OF DEFLECTIONS AND BENDING MOMENTS (OR STRESSES) DERIVED BY THE METHOD OF R. A. E. REPORT NO. STRUCTURES 168. D. Williams. 1956. 11p. diagrs., tabs. (ARC CP 254)

The relative accuracies of moments and deflections, as derived by the method (ref. 1) are discussed, and it is shown that moments are not expected in general to be less accurate than the deflections.

N-44675*

Aeronautical Research Council (Gt. Brit.)
MEASUREMENTS OF PITCHING MOMENT DERIVATIVES FOR A SERIES OF RECTANGULAR WINGS AT LOW WIND SPEEDS. P. R. Guyett and D. E. G. Poulter. 1956. 52p. diagrs., tabs. (ARC CP 249)

The direct aerodynamic moments for pitching oscillations have been measured on a series of rectangular wings having aspect ratios between 2 and 8 for axis positions at the wing leading edges and trailing edges. Two of the wings were also tested with single end plates which were aerodynamically effective in doubling the wing geometric aspect ratio. The measurements were made at low speeds in an open jet wind tunnel and covered the range of frequency parameter (based on wing chord) 0.13 to 0.39. The results are in general agreement with theoretical results due to Lawrence and Gerber. Similar tests were also made on a wing fitted with two end plates in an attempt to obtain results for two-dimensional flow.

INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS. HYDRODYNAMIC STABILITY. PART 21. SOME NOTES ON THE EFFECT OF WAVES ON LONGITUDINAL STABILITY CHARACTERISTICS. D. M. Ridland. 1956. 58p. diagrs., tabs. (ARC CP 237)

Results are given of tests on three models of the series, designed to provide information on the correlation between stability with disturbance and stability in waves. No correlation was observed, but the results are analyzed and compared with previous work, and some important general conclusions drawn as to the nature of disturbed stability and the behavior of flying boats in waves.

N-44677*

Aeronautical Research Council (Gt. Brit.)
INVESTIGATION OF HIGH LENGTH/BEAM RATIO SEAPLANE HULLS WITH HIGH BEAM LOADINGS. HYDRODYNAMIC STABILITY. PART 13. THE EFFECT OF AFTERBODY ANGLE ON STABILITY AND SPRAY CHARACTERISTICS. D. M. Ridland. 1956. 30p. diagrs., photos., tabs. (ARC CP 236)

The effects of afterbody angle on longitudinal stability, spray, and directional stability characteristics and elevator effectiveness are deduced from the results of tests on three models of the series which were alike in every major respect except that of afterbody angle. The models have afterbody angles of 4°, 6°, and 8°, respectively. It was found that increasing afterbody angle improved longitudinal stability characteristics considerably, both with and without disturbance, increased trim generally, gave a slight improvement in spray and directional stability characteristics, and increased elevator effectiveness. The best hydrodynamic configuration was that with the 8° afterbody angle.

A SPECTROPHOTOMETRIC METHOD FOR THE DETERMINATION OF UNSATURATED LINKAGES IN ALKENYL SILANE TREATED GLASS FABRIC. E. J. McLauchlan and B. Bedford. February 1956. 6p. diagr., tabs. (AID Chem. 7)

A method for the determination of unsaturated linkages in alkenyl silane treated glass fabric by the absorption of bromine from a standard solution is described. The residual bromine is extracted and determined spectrophotometrically. An estimate of the amount of finish on the glass fabric may also be obtained.

N-44682*

Royal Aircraft Establishment (Gt. Brit.)
AERODYNAMIC DERIVATIVES FOR TWO CROPPED DELTA WINGS AND ONE ARROWHEAD WING OSCILLATING IN DISTORTION MODES. D. L. Woodcock. April 1956. 69p. tabs. (RAE Structures 201)

Aerodynamic derivatives are given for three particular plan forms oscillating with symmetric distortion modes in incompressible flow. The plan forms are: (1) a cropped delta wing of aspect ratio 3 and taper ratio 1/7; (2) a cropped delta wing of aspect ratio 1.2 and taper ratio 1/7; and (3) an arrowhead wing of aspect ratio 1.32, taper ratio 7/18, and angle of sweep of 63.4^{o} at the quarter chord. The results are for modes of the form $|\eta|^{n}$ for $n = 0(1)4$ where η is a nondimensional spanwise coordinate. They have been determined from intermediate results which D. E. Lehrian had earlier obtained by the vortex lattice method. The results are compared, for some cases, with the corresponding values given by very low-aspect-ratio theory.

Royal Aircraft Establishment (Gt. Brit.)
THE TIMING OF THE ATTEMPT ON THE WORLD AIRSPEED RECORD AT FORD ON 10th MARCH, 1956. N. E. G. Hill, W. Goldsmith, and T. H. Kerr. Appendix VI: MEASUREMENT OF POSITION ERROR ON THE FAIREY DELTA 2 (WG. 774). T. H. Kerr. Appendix VII: DATA REDUCTION FOR THE ANALYSIS OF HEIGHT DURING THE WORLD SPEED RECORD ATTEMPT. T. H. Kerr. May 1956. 38p. diagrs., photos., tabs. (RAE Instn. 9)

On March 10, 1956, Mr. L. P. Twiss flying in a Fairey Delta 2 airplane attempted to establish a new world airspeed record at unrestricted altitude. The attempt was made at a height of about 38,000 feet, over a course 15.6 kilometers long near Ford and Chichester, Sussex, and was timed by a team of R. A. E. engineers who determined the speeds achieved by the airplane, and the variations of height during the attempt. The results show that Mr. Twiss kept his airplane within the height tolerances permitted by the F. A. I. Code Sportif, and that his mean speed for two successive transits of the course in opposite directions was 1822 km/hr (1132 statute miles/hr). The global margin of error of the measurement of speed was 0.033 percent at the 99 percent confidence level.

N-44684*

Royal Aircraft Establishment (Gt. Brit.)
IMPROVED EQUIPMENT FOR TIMING WORLD AIRSPEED RECORDS AT HIGH ALTITUDE. N. E. G. Hill and W. Goldsmith. April 1956. 35p. diagrs., photos. (RAE Instn. 6)

Advances in supersonic flight made it necessary to prepare new timing equipment in anticipation of the first British attempt at high altitude on the world airspeed record under the F. A. I. rules. Various techniques of speed measurement were considered, and the photographic camera and chronometer method was chosen although its use is restricted to clear sky conditions. A camera and an electronic chronometer were specially designed and made for the purpose, and are described in some detail in this report; the technique of setting up, calibrating, and using the equipment, and the monitoring of an airplane's height during a speed record attempt, are also described. An analysis of the random errors to be expected in the distance and time measurements suggests that determination of speed with a margin of error of 1 in 2000 should be possible at a height of 40,000 feet. At greater heights larger errors are to be expected.

N-44690*

Aeronautical Research Council (Gt. Brit.)
SOME TESTS ON THE SPREAD OF VELOCITY IN A COLD JET DISCHARGING WITH EXCESS PRESSURE FROM A SONIC EXIT INTO STILL AIR. J. Seddon and L. Haverty. 1956. 15p. diagrs., photos. (ARC CP 246)

This spread has been examined over the range 40 to 200 diameters from the exit. Jet pressure ratios (outside static pressure + jet total pressure) were

from 0.479 to 0.042, corresponding to isentropic Mach numbers from 1.08 to 2.72. Rates of spread are not greatly different from that for a subsonic jet. The effective exit of an underexpanded jet is, however, displaced some distance downstream of the actual exit. For a jet of isentropic Mach number 1.51, the effective exit position is about 8 diameters downstream and the half-velocity circles lie on a cone of semiangle 5.7° from the center of the effective exit.

National Bureau of Standards. THE CREEP BAHAVIOR OF STRUCTURAL JOINTS OF AIRCRAFT MATERIALS UNDER CONSTANT LOADS AND TEMPERATURES. Leonard Mordfin and Alvin C. Legate. April 20, 1955. 33p. diagrs., tabs. (National Bureau of Standards. Rept. 4052)

A method is described by which the time to rupture and the mode of rupture may be predicted. This method utilizes creep rupture data on the materials from which the joint is fabricated, and its accuracy is within the scatter of the materials data. It is shown that the stress concentrations and the interactions between the tensile, shear, and bearing stresses in a joint do not affect the time to rupture. The test data also indicate that the creep rupture properties of spotwelds are different from those of the parent material. The relative merits of various methods of predicting the times to rupture of joints are discussed.

NACA RM A51H02

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - PLANE TRIANGULAR WING OF ASPECT RATIO 3 WITH NACA 0003-63 SECTION. John C. Heitmeyer. September 1951. 20p. diagrs. (NACA RM A51H02)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination, having a triangular wing of aspect ratio 3 with NACA 0003-63 sections in streamwise planes. Results are shown for Mach numbers from 0.60 to 0.92 and from 1.20 to 1.70 at a Reynolds number of 4.80 million. The variations of the characteristics with Reynolds number are also shown for several Mach numbers.

NACA RM A51H10

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - PLANE 45° SWEPT-BACK WING OF ASPECT RATIO 3, TAPER RATIO 0.4 WITH 3-PERCENT-THICK, BICONVEX SECTION. John C. Heitmeyer. September 1951. 20p. diagrs. (NACA RM A51H10)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a wing-body combination, having a plane 45° sweptback wing of aspect ratio 3 and taper ratio 0.4 with 3-percent-thick biconvex sections in streamwise planes. Results are shown for Mach numbers from 0.60 to 0.92 and from 1.20 to 1.70 at a Reynolds number of 3.83 million. The variation of the characteristics with Reynolds number is also shown for several Mach numbers.

NACA RM A51H22

LIFT, DRAG, AND PITCHING MOMENT OF LOW-ASPECT-RATIO WINGS AT SUBSONIC AND SUPERSONIC SPEEDS - BODY OF REVOLUTION. John C. Heitmeyer. October 1951. 10p. diagrs. (NACA RM A51H22)

This report presents the results of an investigation to ascertain the lift, drag, and pitching moment of a body of revolution. Results are shown for Mach numbers from 0.60 to 0.92 and from 1.20 to 1.70 at Reynolds numbers of 0.64 million, 1.02 million, and 1.59 million.

NACA RM A54H12a

THE EFFECT OF WING PROFILE ON THE TRANSONIC CHARACTERISTICS OF RECTANGULAR AND TRIANGULAR WINGS HAVING ASPECT RATIOS OF 3 - TRANSONIC BUMP TECHNIQUE. Warren H. Nelson and Joseph L. Frank. October 1954. 33p. diagrs., photo., tab. (NACA RM A54H12a)

Lift, drag, and pitching-moment data are compared for five wings having NACA 63A004, NACA 2-004, and circular-arc profiles. The Mach number range of the tests, in general, was from 0.6 to 1.10 with a Reynolds number range of 1.7 million to 2.8 million. The results indicate that in the transonic Mach number range, these variations in profile had no major effects on the wing characteristics.

NACA RM A54H26

TESTS IN THE AMES 40- BY 80-FOOT WIND TUNNEL OF THE AERODYNAMIC CHARACTERISTICS OF AIRPLANE MODELS WITH PLAIN SPOILER AILERONS. Ralph W. Franks. December 1954. 47p. diagrs., photo., tabs. (NACA RM A54H26)

Data are presented of tests of four wing plan forms equipped with plain spoiler ailerons. For most of the tests the spoilers were mounted along the 70-percent-chord line normal to the wing surface. They were of constant-percent-chord height. Heights of 5-, 10-, and 15-percent chord were tested. The tests were made at Reynolds numbers from 7 to 13 million and at Mach number of 0.13. The data are presented without discussion.

NACA RM A54H26a

THE APPLICATION OF A SIMPLIFIED LIFTING-SURFACE THEORY TO THE PREDICTION OF THE ROLLING EFFECTIVENESS OF PLAIN SPOILER AILERONS AT SUBSONIC SPEEDS. Ralph W. Franks. December 1954. 29p. diagrs., tab. (NACA RM A54H26a)

A method is described for predicting the subsonic rolling effectiveness at zero angle of attack of spoiler ailerons on straight or sweptback wings. A simplified lifting-surface flap theory is used in conjunction with two-dimensional spoiler data and an empirical factor for the effective spanwise location on swept wings. A comparison is made of the predicted rolling moments with experimentally obtained values.

NACA RM E51H17

AERODYNAMIC CHARACTERISTICS OF A SLENDER CONE-CYLINDER BODY OF REVOLUTION AT A MACH NUMBER OF 3.85. John R. Jack. November 1951. 24p. diagrs., photos. (NACA RM E51H17)

An experimental investigation of the aerodynamics of a slender cone-cylinder body of revolution was conducted at a Mach number of 3.85 for angles of attack of 0° to 10° and a Reynolds number of 3.85×10^{6}. Boundary-layer measurements at zero angle of attack are compared with the compressible-flow formulations for predicting laminar boundary-layer characteristics. Comparison of experimental pressure and force values with theoretical values showed relatively good agreement for small angles of attack. The measured mean skin-friction coefficients agreed well with theoretical values obtained for laminar flow over cones.

NACA RM E51H21

PRELIMINARY INVESTIGATION OF COOLING-AIR EJECTOR PERFORMANCE AT PRESSURE RATIOS FROM 1 TO 10. C. W. Ellis, D. P. Hollister, and A. F. Sargent, Jr. October 1951. 21p. diagrs. (NACA RM E51H21)

Preliminary investigation was made of conical cooling-air ejectors at primary pressure ratios from 1 to 10. The cooling-air flow was maintained at zero and the resulting pressure variation in the shroud indicated pumping ability. The gross thrusts of the ejector and nozzle were compared. Several ratios of the spacing between the nozzle and shroud exit to the nozzle exit diameter were investigated for several shroud to nozzle exit diameter ratios. Maximum gross thrust loss occurred under conditions of zero cooling-air flow and was as much as 35 percent below nozzle jet thrust. For minimum thrust loss, ejectors should be designed with as low diameter and spacing ratio as possible.

NACA RM E52H21

EFFECT OF FUEL ADDITIVES ON CARBON DEPOSITION IN A J33 SINGLE COMBUSTOR. I - THREE METALLIC-ORGANIC ADDITIVES. Edmund R. Jonash, Jerrold D. Wear, and William P. Cook. October 1952. 12p. diagrs., photos., tabs. (NACA RM E52H21)

An investigation was conducted in a J33 single combustor to determine the effects of three fuel additives on the carbon-deposition characteristics of MIL-F-5624A fuel, grades JP-3 and JP-4, and an aromatic fuel blend. The additives considered included a commercial fuel-oil additive (containing cobalt and lead compounds), tetraethyl lead, and lead naphthenate. The combustor was operated for 4-hour periods at simulated full-scale operating conditions at 90 percent of normal rated engine speed, zero Mach number, and 20,000-foot altitude. Small concentrations of all additives reduced carbon deposition significantly. A 0.1-percent concentration of the

fuel-oil additive in JP-3 fuel reduced carbon deposition 23 percent. Of the two lead additives tested, lead naphthenate was the more effective; a 0.005-percent concentration of this additive reduced the carbon deposition obtained with a highly aromatic fuel blend 66 percent. For at least two of the additives tested, there appeared to be optimum concentrations; larger concentrations caused significant metallic-compound deposition which was included in the reported deposition. The effectiveness of the lead naphthenate additive varied considerably for two widely different fuels considered, an aromatic fuel blend and a JP-4 fuel.

INVESTIGATION OF MECHANICAL FASTENINGS FOR SOLID TURBINE BLADES MADE FROM DUCTILE MATERIALS. André J. Meyer, Jr., Albert Kaufman, and W. C. Caywood. August 1954. 45p. diagrs., photos., tabs. (NACA RM E54E21)

Three fir-tree root designs were evaluated in short- and long-time pull tests at temperatures up to 1500° F. The root strength was found to depend on the cross-sectional areas carrying the load and not on the size or number of serrations. The strengths correlated well with the properties of the root materials.

NACA RM E54H12
National Advisory Committee for Aeronautics.
ANALYTICAL DETERMINATION OF EFFECT OF TURBINE COOLING-AIR-IMPELLER PERFORMANCE ON ENGINE PERFORMANCE AND COMPARISON OF EXPERIMENTALLY DETERMINED PERFORMANCE OF IMPELLERS WITH AND WITHOUT INDUCER VANES. Louis J. Schafer, Jr., and Robert O. Hickel. October 1954. 44p. diagrs., photos. (NACA RM E54H12)

An analysis was made of the effect of impeller performance on turbojet-engine thrust and specific fuel consumption for two coolant-flow ratios at 70 and 100 percent of rated engine speed. Experimentally determined total-pressure ratios across two cooling-air impellers having different designs, one with straight radial vanes and the other with an inducer section at the vane inlet, were compared over a range of engine speed and cooling-air weight flow. The analysis showed a small effect of impeller performance.

NACA RM E54H20
National Advisory Committee for Aeronautics.
METHOD OF DESIGNING CORRUGATED SURFACES HAVING MAXIMUM COOLING EFFECTIVENESS WITHIN PRESSURE-DROP LIMITATIONS FOR APPLICATION TO COOLED TURBINE BLADES. Henry O. Slone, James E. Hubbartt, and Vernon L. Arne. December 1954. 103p. diagrs., tab., charts. (NACA RM E54H20)

A method utilizing charts is presented for the systematic determination of a corrugation geometry configuration which, for a specific application to an air-cooled turbine blade, gives the required amount of blade temperature reduction using the minimum amount of coolant flow within pressure-drop limitations. The cooling effectiveness varies appreciably with changes in corrugation geometry, and these changes may be reflected in improvements in the coolant flow and pressure requirements for air-cooled turbine blades. A numerical example is included to illustrate use of the method.

NACA RM E54H23
National Advisory Committee for Aeronautics.
EFFECT OF FUEL ADDITIVES ON CARBON DEPOSITION IN A J33 SINGLE COMBUSTOR. II - SEVEN COMMERCIAL ORGANO-METALLIC ADDITIVES. Vincent F. Hlavin and William P. Cook. November 1954. 12p. diagrs., photos., tabs. (NACA RM E54H23)

Investigations with seven organo-metallic additives in a No. 2 furnace oil (NACA fuel 53-193) and additional tests with two of these additives in a minimum quality MIL-F-5624A, grade JP-4, fuel (NACA fuel 54-41) were conducted to determine their effectiveness in reducing carbon deposits in a J33 single combustor operating at zero flight Mach number, 20,000-foot altitude, and 90-percent rated speed for a 4-hour period. Six of the seven additives in concentrations of 1/4 to 1 gallon per 1000 gallons of fuel reduced carbon deposits of the furnace oil more than 60 percent. The two additives in the JP-4 fuel were less effective in reducing carbon than when used in the furnace oil.

NACA RM E55F30a
National Advisory Committee for Aeronautics.
EFFECT OF FUEL ADDITIVES ON CARBON DEPOSITION IN A J33 SINGLE COMBUSTOR. III - FIVE ORGANO-METALLIC ADDITIVES. Edmund R. Jonash and William P. Cook. September 1955. 11p. diagrs., photos., tabs. (NACA RM E55F30a)

The effectiveness of three commercial additives containing lead and two organo-metallic compounds, cadmium naphthenate and dicyclopentadienyliron, in reducing carbon formation of a low-volatility jet-type fuel was studied in a single turbojet combustor. The largest reduction in carbon deposits, about 80 percent, was obtained with dicyclopentadienyliron. The commercial additives were somewhat less effective, and cadmium naphthenate was ineffective. None of the additives affected exhaust-gas-smoke concentration.

CONTROL EFFECTIVENESS LOAD AND HINGE-MOMENT CHARACTERISTICS OF A TIP CONTROL SURFACE ON A DELTA WING AT A MACH NUMBER OF 1.9. D. William Conner and Ellery B. May, Jr. October 7, 1949. 41p. diagrs., photo. (NACA RM L9H05)

A half-delta control flap composing the outer one-third of a semispan delta wing swept back 60° was tested at control deflections up to 12° and at small angles of attack in the Langley 9- by 12-inch supersonic blowdown tunnel. Aerodynamic data were obtained for the complete wing and for the control alone tested in the presence of the wing. The test Reynolds number was 4×10^6. Comparison is made with rocket test results and with linearized theory.

NACA RM L9H26
National Advisory Committee for Aeronautics.
CONTROL EFFECTIVENESS AND HINGE-MOMENT CHARACTERISTICS OF A TIP CONTROL SURFACE ON A LOW-ASPECT-RATIO POINTED WING AT A MACH NUMBER OF 1.9. D. William Conner and Ellery B. May, Jr. October 5, 1949. 28p. diagrs., photo. (NACA RM L9H26)

A control flap composing the outer 28 percent of a pointed semispan wing of aspect ratio 1.7 was tested through a range of control deflections and at small angles of attack in the Langley 9- by 12-inch supersonic blowdown tunnel. Aerodynamic data were obtained for the complete wing, while normal-force and hinge-moment data were obtained for the control surface. The test Reynolds number was 4,900,000. Comparison is made with test results of a similar wing-control-surface configuration having different conditions of trailing-edge sweep.

NACA RM L9H30

FLIGHT INVESTIGATION FROM HIGH SUBSONIC TO SUPERSONIC SPEEDS TO DETERMINE THE ZERO-LIFT DRAG OF A TRANSONIC RESEARCH VEHICLE HAVING WINGS OF 45° SWEEPBACK, ASPECT RATIO 4, TAPER RATIO 0.6, AND NACA 65A006 AIRFOIL SECTIONS. Ellis Katz. October 27, 1949. 16p. diagrs., photos., tab. (NACA RM L9H30)

Rocket-powered flight tests were made at high subsonic, transonic, and supersonic speeds and at high Reynolds numbers to determine the zero-lift drag and base pressure of a transonic wing-body and body-alone configuration. The test wing was of 45° sweepback, aspect ratio 4, taper ratio 0.6, and NACA 65A006 airfoil section. The body had a fineness ratio of 10 and a frontal area equal to 6.06 percent of the wing-plan-form area.

NACA RM L9K25a

PRELIMINARY RESULTS FROM A FREE-FLIGHT INVESTIGATION AT TRANSONIC AND SUPERSONIC SPEEDS OF THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF AN AIRPLANE CONFIGURATION WITH A THIN STRAIGHT WING OF ASPECT RATIO 3. Clarence L. Gillis, Robert F. Peck, and A. James Vitale. February 14, 1950. 53p. diagrs., photos., tabs. (NACA RM L9K25a)

A flight test was conducted on a rocket-propelled airplane model having a thin straight tapered wing of aspect ratio 3 and hexagonal airfoil sections. The Mach number range covered was from 0.75 to 1.42. Aerodynamic derivatives defining the longitudinal stability, control, trim, and drag characteristics of the configuration were obtained over all or part of this Mach number range. The variation of the various aerodynamic quantities with Mach number in the transonic region was fairly gradual, no unusual stability or control problems being encountered.

BUFFETING INFORMATION OBTAINED FROM ROCKET-PROPELLED AIRPLANE MODELS HAVING THIN UNSWEPT WINGS. Clarence L. Gillis. October 18, 1950. 15p. diagrs., photos. (NACA RM L50H22a)

Flight tests were conducted on rocket-propelled models of an airplane configuration having an unswept low-aspect-ratio wing with 4.5-percent-thick hexagonal airfoil sections. A high positive lift-coefficient range was covered in the Mach number range from 0.75 to 1.35. In the subsonic range some maximum-lift and buffeting information was obtained. Buffeting occurred at a lift coefficient only a little below the maximum. At Mach numbers of 1.0 and above no evidence of buffeting appeared in the lift-coefficient range covered in the tests.

ROCKET-MODEL INVESTIGATION TO DETERMINE THE FORCE AND HINGE-MOMENT CHARACTERISTICS OF A HALF-DELTA TIP CONTROL ON A 59° SWEPTBACK DELTA WING BETWEEN MACH NUMBERS OF 0.55 AND 1.43. C. William Martz, James D. Church, and John W. Goslee. October 1952. 53p. diagrs., photos., tab.
(NACA RM L52H06)

Control-force and hinge-moment characteristics were obtained from a free-flight test of a rocket-powered model equipped with 60° sweptback half-delta tip controls mounted on a 59° sweptback delta wing. Data were obtained for deflections up to ±10° and for angles of attack from ±3° to ±11° between the Mach numbers of 0.55 and 1.43. Comparisons are made with linearized theory and other rocket-test results.

NACA RM L52H08a
National Advisory Committee for Aeronautics.
AN INVESTIGATION AT TRANSONIC SPEEDS OF THE AERODYNAMIC CHARACTERISTICS OF AN AIR INLET INSTALLED IN THE ROOT OF A 45° SWEPTBACK WING. Robert R. Howell and Arvid L. Keith, Jr. October 1952. 47p. diagrs., photos., tabs.
(NACA RM L52H08a)

An investigation has been made in the Langley transonic blowdown tunnel to determine the lift and drag increments due to installation of a triangular-shaped air inlet in the root of a 45° sweptback wing and to study the internal flow characteristics of the inlet. The tests were conducted for a Mach number range from 0.80 to 1.41 at a Reynolds number of approximately 6.5 x 10^6. The measurements included total-pressure recovery at the inlet and at an assumed engine compressor-face station and the lift and drag for ranges of angle of attack and inlet mass-flow ratio from -2.0° to 8.2°, and from 0.34 to 0.77, respectively.

NACA RM L52H13

CONTROL HINGE-MOMENT AND EFFECTIVENESS CHARACTERISTICS OF A 60° HALF-DELTA TIP CONTROL ON A 60° DELTA WING AT MACH NUMBERS OF 1.41 AND 1.96. Lawrence D. Guy. October 1952. 40p. diagrs., photo., tab.
(NACA RM L52H13)

A wind-tunnel investigation has been made of a half-delta wing-tip control on a semispan 60° delta-wing—fuselage combination at Mach numbers of 1.41 and 1.96 and at Reynolds numbers of 2.4 and 2.0, respectively. Control-surface hinge moments and bending moments, as well as aerodynamic characteristics of the complete wing-fuselage combination, were obtained throughout a maximum control-deflection range of ±30° and at angles of attack as high as 24°. Comparison is made with previous wind-tunnel test results and with linearized theory. A mathematical analysis of the optical system, used to measure control-surface hinge moments and bending moments, is included in the appendix.

NACA RM L52H14
National Advisory Committee for Aeronautics.
THE LONGITUDINAL STABILITY AND CONTROL CHARACTERISTICS OF A 60° DELTA-WING MISSILE HAVING HALF-DELTA TIP CONTROLS AS OBTAINED FROM A FREE-FLIGHT INVESTIGATION AT TRANSONIC AND SUPERSONIC SPEEDS. Martin T. Moul and Hal T. Baber, Jr. October 1952. 35p. diagrs., photos. (NACA RM L52H14)

A 60° delta-wing missile configuration having half-delta tip controls has been flight-tested by means of a rocket-propelled model. The square-wave pulsed-control technique was utilized to determine longitudinal stability derivatives, control effectiveness, and drag characteristics as the model decelerated through the Mach number range 1.65 to 0.70.

National Advisory Committee for Aeronautics.
PRELIMINARY TANK TESTS OF SOME HYDRO-SKI-WHEEL COMBINATIONS IN THE PLANING CONDITION. Norman S. Land and Rudolph E. Fontana. October 1952. 71p. diagrs. (NACA RM L52H15)

A preliminary investigation was made of the planing characteristics of a few combinations of a wheel and a hydro-ski. The models that were tested included at least two values of the following parameters: Diameter of wheel, width of wheel, cross-section shape of wheel, fore-and-aft location of wheel, lateral location of wheel, gap between wheel and ski, rotation of wheel, protrusion of wheel, and dead rise of ski. The data gathered are presented in the form of plots of resistance, trimming moment, and wetted length against speed at various values of load and trim.

NACA RM L52H18
National Advisory Committee for Aeronautics.
SOME EFFECTS OF SPOILER HEIGHT, WING FLEXIBILITY, AND WING THICKNESS ON ROLLING EFFECTIVENESS AND DRAG OF UNSWEPT WINGS AT MACH NUMBERS BETWEEN 0.4 AND 1.7.
E. M. Fields. October 1952. 20p. diagrs., photo.
(NACA RM L52H18)

Rolling effectiveness and drag tests have been conducted over the Mach number range from 0.4 to 1.7 by the Langley Pilotless Aircraft Research Division utilizing rocket-propelled test vehicles in free flight. The wings with an aspect ratio of 3.7 were unswept and untapered, varied in thickness ratio from 3 percent to 9 percent, and had full-span, solid, sharp-edge spoilers located at the 0.8-chord line. Increasing the wing flexibility increased the rolling effectiveness at subsonic speeds and decreased it at supersonic speeds. Increasing the spoiler height increased the rolling effectiveness linearly near $M = 1.0$ but the increase was nonlinear at the other speeds tested. The rigid-wing rolling effectiveness of the 3-percent-thick wing, compared with that of the 9-percent-thick wing, was lower at subsonic speeds, higher at low supersonic speeds, and about the same at speeds above $M = 1.3$. The drag generally increased linearly with increased spoiler height except at the lower supersonic speeds.

NACA RM L52H29
National Advisory Committee for Aeronautics.
EFFECTS OF THE SPANWISE, CHORDWISE, AND VERTICAL LOCATION OF AN EXTERNAL STORE ON THE AERODYNAMIC CHARACTERISTICS OF A 60° DELTA WING AT MACH NUMBERS OF 1.41, 1.62, AND 1.96. Carl R. Jacobsen. October 1952. 34p. diagrs. (NACA RM L52H29)

An investigation has been made in the Langley 9- by 12-inch supersonic blowdown tunnel to determine the effects of external store location on the lift, drag, and pitching-moment characteristics of a 60° delta wing at Mach numbers of 1.41, 1.62, and 1.96. The chordwise and vertical location of a store having a Douglas Aircraft Company, Inc., store shape of fineness ratio 8.58 was systematically varied at 40 and 60 percent of the wing semispan. For a wing area of 750 square feet, the store would have sufficient volume to contain about 400 gallons of fuel.

NACA RM L53H04
National Advisory Committee for Aeronautics.
PRESSURE DISTRIBUTIONS ON THREE BODIES OF REVOLUTION TO DETERMINE THE EFFECT OF REYNOLDS NUMBER UP TO AND INCLUDING THE TRANSONIC SPEED RANGE. John M. Swihart and Charles F. Whitcomb. October 1953. 39p. diagrs., photo., tab. (NACA RM L53H04)

The effects of varying Reynolds number on the pressure distribution over a transonic body of revolution are presented. Angles of attack from -2° to 15° were investigated through a Mach number range from 0.60 to 1.09. The Reynolds number based on body length varied from 9×10^6 to 39×10^6, and on maximum diameter from 1.35×10^5 to 4.53×10^5. There were small effects of Reynolds number on the axial pressure distributions of these bodies. These effects were of such a nature as to cause an increase of 0.05 in the normal-force coefficient of the body when tested in the subcritical cross-flow Reynolds number range. A comparison between experimental values of incremental pressure coefficient due to angle of attack and theoretical values was made.

NACA RM L53H14a
National Advisory Committee for Aeronautics.
LOW-SPEED LONGITUDINAL CHARACTERISTICS OF TWO UNSWEPT WINGS OF HEXAGONAL AIRFOIL SECTIONS HAVING ASPECT RATIOS OF 2.5 AND 4.0 WITH FUSELAGE AND WITH HORIZONTAL TAIL LOCATED AT VARIOUS VERTICAL POSITIONS.
William M. Hadaway and Patrick A. Cancro.
October 1953. 29p. diagrs., photos.
(NACA RM L53H14a)

Tests have been conducted in the Langley 19-foot pressure tunnel to determine the low-speed horizontal tail effectiveness and static longitudinal characteristics of two unswept wings of aspect ratios 2.5 and 4.0. Both wings had a taper ratio of 0.625 and modified double-wedge 6-percent-chord airfoil sections. Comparisons of the two wings are presented. Tests were made with circular fuselages attached to the wings with and without full-span drooped leading edges and part-span trailing-edge flaps. A horizontal tail at three vertical locations was tested on each configuration. Tests were made at a Mach number of 0.15 corresponding to Reynolds numbers of 6.2×10^6 for the aspect-ratio-4.0 wing and 7.6 for the aspect-ratio-2.5 wing.

NACA RM L53H19a
National Advisory Committee for Aeronautics.
LOW-SPEED INVESTIGATION OF THE EFFECTS OF LOCATION OF A DELTA HORIZONTAL TAIL ON THE LONGITUDINAL STABILITY AND CONTROL OF A FUSELAGE AND THIN DELTA WING WITH DOUBLE SLOTTED FLAPS INCLUDING THE EFFECTS OF A GROUND BOARD. John M. Riebe and Jean C. Graven, Jr. October 1953. 38p. diagrs., tabs. (NACA RM L53H19a)

Results are presented of a wind-tunnel investigation at low speeds of the effect of horizontal-tail location on longitudinal stability and control characteristics of a fuselage and a thin delta wing with double slotted flaps including the effects of a ground board. Satisfactory locations of horizontal tail with flaps deflected were indicated to be lower and more rearward than for the flap-retracted condition. Ground board effects with flaps deflected were similar to the results of previous investigations of other wing plan forms with flaps deflected.

NACA RM L53H24
National Advisory Committee for Aeronautics.
WIND-TUNNEL INVESTIGATION OF THE EFFECTS OF A FENCE AND A LEADING-EDGE NOTCH ON THE AERODYNAMIC LOADING CHARACTERISTICS IN PITCH OF A 45° SWEPTBACK WING AT HIGH SUBSONIC SPEEDS. Richard E. Kuhn, James W. Wiggins, and Andrew L. Byrnes, Jr. October 1953. 56p. diagrs., photo., tabs. (NACA RM L53H24)

The aerodynamic loading characteristics of a 45° sweptback wing of aspect ratio 4, in combination

with a fuselage, as obtained from pressure-distribution measurements are presented for the clean wing and for the wing with fences and leading-edge notches. The tests covered a Mach number range from 0.50 to 0.95 and angles of attack up to 24°.

NACA RM L54H03

THE EFFECT OF GROUND ON THE LOW-SPEED AERODYNAMIC, CONTROL, AND CONTROL HINGE-MOMENT CHARACTERISTICS OF A DELTA-WING—FUSELAGE MODEL WITH TRAILING-EDGE CONTROLS. William I. Scallion. September 1954. 52p. diagrs., photos., tabs. (NACA RM L54H03)

Results are presented of an investigation to determine the low-speed aerodynamic, control, and control hinge-moment characteristics near the ground of a 60° sweptback delta-wing—fuselage combination with trailing-edge and horn-balance-type controls of 10.8 and 10.2 percent total wing area, respectively. The airfoil section was NACA 65A003 parallel to model axis of symmetry and the aspect ratio was 2.31. The Reynolds number was 2.3×10^6 and the Mach number was 0.10.

NACA RM L54H10

WATER-IMPACT THEORY FOR AIRCRAFT EQUIPPED WITH NONTRIMMING HYDRO-SKIS MOUNTED ON SHOCK STRUTS. Emanuel Schnitzer. October 1954. 29p. diagrs. (NACA RM L54H10)

Theoretical equations are derived for the motions of aircraft equipped with shock-mounted hydro-skis impacting on a water surface. A rough approximation to the hydrodynamic-force term is included in a non-dimensional form which permits design-trend study solutions for a wide range of practical impacts. A second, better approximation to the hydrodynamic force is included in a dimensional form. This form allows solutions for various bottom shapes, shock-strut spring types, and exponential damping constants. An appendix gives a simple step-by-step procedure for solving any of the sets of equations derived in the paper.

NACA RM L54H12

WIND-TUNNEL INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE STATIC LONGITUDINAL STABILITY CHARACTERISTICS OF A COMPLETE MODEL HAVING CROPPED-DELTA, SWEPT, AND UNSWEPT WINGS AND SEVERAL HORIZONTAL-TAIL HEIGHTS. Kenneth W. Goodson and Robert E. Becht. October 1954. 44p. diagrs. (NACA RM L54H12)

The present paper presents static longitudinal stability characteristics at high subsonic speeds of a complete model having a cropped delta wing, a swept wing (quarter-chord line swept 30°), and an unswept (50-percent-chord line unswept) wing and having several horizontal-tail heights. These midwings were of aspect ratio 3 and had taper ratios of 0.143, 0.50, and 0.20, respectively.

NACA RM L54H23

AN INVESTIGATION AT HIGH SUBSONIC SPEEDS OF THE PRESSURE DISTRIBUTIONS ON A 45° SWEPTBACK VERTICAL TAIL IN SIDESLIP WITH AND WITHOUT A 45° SWEPTBACK HORIZONTAL TAIL LOCATED ON THE FUSELAGE CENTER LINE. Harleth G. Wiley and William C. Moseley, Jr. November 1954. 81p. diagrs., photos., 7 tabs. (NACA RM L54H23)

This paper presents the chordwise pressure distributions at high subsonic speeds on a 45° sweptback, untapered vertical tail in sideslip with and without a 45° sweptback, untapered horizontal tail mounted on the fuselage center line. Tests were made at 0°, 4°, and 12° angle of attack through a sideslip range of about -2° to 23° and over a Mach number range of 0.60 to 0.95. Presented are integrated span loadings and section normal-force and moment coefficients for all tests, as well as typical chordwise pressure distributions at six spanwise stations of the vertical tail.

NACA RM L54H25

A TRANSONIC WIND-TUNNEL INVESTIGATION OF THE LONGITUDINAL FORCE AND MOMENT CHARACTERISTICS OF A PLANE AND A CAMBERED 3-PERCENT-THICK DELTA WING OF ASPECT RATIO 3 ON A SLENDER BODY. Dale L. Burrows and William E. Palmer. November 1954. 31p. diagrs., photos., tab. (NACA RM L54H25)

Wind-tunnel tests at Mach numbers from 0.76 to 1.38 have been made on two delta-wing—body combinations to obtain lift, drag, pitching-moment, and base-pressure data at angles of attack from 0° to 20° and at Reynolds numbers of about 5×10^6. A plane wing and a cambered-leading-edge wing with three-percent thickness ratios and an aspect ratio of 3 were tested. Camber provided improvements in maximum lift-drag ratio throughout the Mach number range and improvements in longitudinal stability at high lift and high subsonic Mach numbers.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1247

CHARACTERISTICS OF TURBULENCE IN A BOUNDARY LAYER WITH ZERO PRESSURE GRADIENT. P. S. Klebanoff, National Bureau of Standards. 1955. ii, 19p. diagrs. (NACA Rept. 1247. Supersedes TN 3178)

The results of an experimental investigation of a turbulent boundary layer with zero pressure gradient are presented. Measurements with the hot-wire anemometer were made of turbulent energy and turbulent shear stress, probability density and flattening factor of u-fluctuation, spectra of turbulent energy and shear stress, and turbulent dissipation. The importance of the region near the wall and the inadequacy of the concept of local isotropy are demonstrated. Attention is given to the energy balance and the intermittent character of the outer region of the boundary layer. Also several interesting features of the spectral distribution of the turbulent motions are discussed.

NACA RM E56D23

THEORETICAL PERFORMANCE OF JP-4 FUEL AND LIQUID OXYGEN AS A ROCKET PROPELLANT. II - EQUILIBRIUM COMPOSITION. Vearl N. Huff, Anthony Fortini, and Sanford Gordon. September 1956. 47p. diagrs., tabs. (NACA RM E56D23)

Data were calculated for equivalence ratios of 1 to 3, chamber pressures of 300 and 600 pounds per square inch absolute, and pressure ratios of 1 to 1500. Parameters included are specific impulse, combustion and exit temperature, molecular weight, characteristic velocity, coefficient of thrust, ratio of nozzle-exit area to throat area, specific heat at constant pressure, isentropic exponent, viscosity, and thermal conductivity. A correlation is given which permits determination of performance for a wide range of chamber pressures.

NACA TM 1416

TESTS TO DETERMINE THE ADHESIVE POWER OF PASSENGER-CAR TIRES. (Versuche zur Feststellung des Haftvermögens von Personenwagen-Bereifungen). B. Förster. August 1956. 36p. diagrs., photos., tab. (NACA TM 1416. Trans. from Deutsche Kraftfahrtforschung, no. 22)

Experimental data on braking coefficients of friction and cornering characteristics for automobile tires are presented. Although the particular types of tires investigated are not of direct interest to the aircraft industry, the data do serve to indicate certain basic aspects of tire behavior and should be of interest to those concerned with the study of tire braking and cornering characteristics. The effects of the following factors are indicated: (a) forward speed, (b) tire loading, (c) tire pressure, (d) form stiffness of tire, (e) tire size, (f) tread pattern, (g) road surface material and condition, and (h) the effects of braking on cornering characteristics.

NACA TM 1419

EFFECTS OF INTERMITTENT VERSUS CONTINUOUS HEATING UPON THE TENSILE PROPERTIES OF 2024-T4, 6061-T6, AND 7075-T6 ALLOYS. G. W. Stickley and H. L. Anderson, Aluminum Company of America. August 1956. 7p. tabs. (NACA TM 1419)

The object of these tests was to determine the effects of intermittent and continuous heating at 300 and 400° F, for total periods of 100 and 200 hours, upon the tensile properties of 2024-T4 and 6061-T6 alloy rolled-and-drawn rod and 7075-T6 alloy extrusions, at room temperature and at the temperature of heating. The effects of intermittent heating were found to be cumulative and the same as for continuous heating.

NACA TN 3709

AERODYNAMIC INVESTIGATION OF A PARABOLIC BODY OF REVOLUTION AT MACH NUMBER OF 1.92 AND SOME EFFECTS OF AN ANNULAR SUPERSONIC JET EXHAUSTING FROM THE BASE. Eugene S. Love. September 1956. 62p. diagrs., photos., tab. (NACA TN 3709. Supersedes RM L9K09)

An aerodynamic investigation of a slender pointed parabolic body of revolution was conducted at a Mach number of 1.92 with and without the effects of an annular supersonic jet exhausting from the base. Measurements with the jet inoperative were made of lift, drag, pitching moment, base pressures, and radial and axial pressures. With the jet in operation, pressure measurements were made over the rear of the body with the primary variables being angle of attack, ratio of jet velocity to stream velocity, and ratio of pressure at jet exit to stream pressure.

NACA TN 3722

GENERAL THEORY OF WAVE-DRAG REDUCTION FOR COMBINATIONS EMPLOYING QUASI-CYLINDRICAL BODIES WITH AN APPLICATION TO SWEPT-WING AND BODY COMBINATIONS. Jack N. Nielsen and William C. Pitts. September 1956. 79p. diagrs. (NACA TN 3722. Supersedes RM A55B07)

An analysis is made of wave-drag reduction for wing and quasi-cylindrical body combinations produced by changes in cross-sectional shape and in area distribution. The theory, applicable at all supersonic speeds, has been applied to a swept-wing and body combination with sonic leading and trailing edges. A reduction of 22 percent of the wave drag of the winged part of the undistorted combination was achieved by utilizing the optimum axially symmetric indentation, and a further reduction of 42 percent was achieved by distortion of cross-sectional shape. An analytical expression for the optimum axially symmetric indentation is obtained by an alternate method.

NACA TN 3743

AN OPTIMUM SWITCHING CRITERION FOR A THIRD-ORDER CONTACTOR ACCELERATION CONTROL SYSTEM. Anthony L. Passera and Ross G. Willoh, Jr. August 1956. 46p. diagrs., tab. (NACA TN 3743)

A switching criterion for optimum performance of a third-order contactor acceleration control system having complex roots is presented. Analytical and analog-computer methods are utilized to determine this criterion. The resulting optimum transient responses are presented and compared with those of an equivalent linear system.

NACA TN 3745

TRANSITION-FLIGHT TESTS OF A MODEL OF A LOW-WING TRANSPORT VERTICAL-TAKE-OFF AIRPLANE WITH TILTING WING AND PROPELLERS. Powell M. Lovell, Jr., and Lysle P. Parlett. September 1956. 30p. diagrs., photo., tab. (NACA TN 3745)

An investigation of the stability and control of a low-wing four-engine transport vertical-take-off airplane during the transition from hovering to normal forward flight has been conducted with a remotely controlled free-flight model. The model had four propellers distributed along the wing with the thrust axes in the wing-chord plane. The wing could be rotated to 90° incidence so that the propeller thrust axes were vertical for hovering flight.

NACA TN 3751

A STUDY OF THE EFFICIENCY OF HIGH-STRENGTH, STEEL, CELLULAR-CORE SANDWICH PLATES IN COMPRESSION. Aldie E. Johnson, Jr., and Joseph W. Semonian. September 1956. 26p. diagrs., tab. (NACA TN 3751)

Structural efficiency curves are presented for high-strength, stainless-steel, cellular-core sandwich plates of various proportions subjected to compressive end loads for temperatures of 80° F and 600° F. Optimum proportions of sandwich plates for any value of the compressive loading intensity can be determined from the curves. The efficiency of steel sandwich plates of optimum proportions is compared with the efficiency of solid plates of high-strength steel and aluminum and titanium alloys at the two temperatures.

NACA TN 3752

TENSILE PROPERTIES OF AZ31A-0 MAGNESIUM-ALLOY SHEET UNDER RAPID-HEATING AND CONSTANT-TEMPERATURE CONDITIONS. Ivo M. Kurg. August 1956. 21p. diagrs., tabs. (NACA TN 3752)

Specimens of AZ31A-0 magnesium-alloy sheet were heated to rupture at nominal rates of 0.2° F to 100° F per second under constant tensile load conditions. The data are presented and compared with the results of conventional tensile stress-strain tests at elevated temperatures after 1/2-hour exposure. A temperature-rate parameter was used to construct master curves from which stresses and temperatures for yield and rupture can be predicted under rapid-heating conditions. A comparison of the elevated-temperature tensile properties of AZ31A-0 and HK31XA-H24 magnesium-alloy sheet under both constant-temperature and rapid-heating conditions is included.

NACA TN 3821

FLIGHT TECHNIQUES FOR DETERMINING AIRPLANE DRAG AT HIGH MACH NUMBERS. De E. Beeler, Donald R. Bellman, and Edwin J. Saltzman. (Presented to Flight Test Panel of Advisory Group for Aeronautical Research and Development, Brussels, Belgium, August 27-31, 1956). August 1956. 40p. diagrs., photos. (NACA TN 3821)

The accelerometer method has proved to be the most satisfactory method for the flight measurement of total airplane drag during research investigations of high-speed airplanes by the NACA High-Speed Flight Station. The method requires special instrumentation and measuring techniques which are described in detail. Methods for separating the flight-measured overall drag into drag components and for comparing the flight data with wind-tunnel-model data are presented.

NACA TN 3856

FATIGUE-CRACK PROPAGATION IN ALUMINUM-ALLOY BOX BEAMS. Herbert F. Hardrath, Herbert A. Leybold, Charles B. Landers, and Louis W. Hauschild. August 1956. 33p. diagrs., photo. (NACA TN 3856)

Eighteen box-beam specimens constructed according to four designs were subjected to fatigue tests to study fatigue-crack propagation and accompanying stress redistribution. At least two specimens of each design were constructed from each of the aluminum alloys 2024-T3 and 7075-T6.

NACA TN 3859

COMPARISON OF FLIGHT AND WIND-TUNNEL MEASUREMENTS OF HIGH-SPEED-AIRPLANE STABILITY AND CONTROL CHARACTERISTICS. Walter C. Williams, Hubert M. Drake, and Jack Fischel. (The information in this report was also contained in a paper by the same authors which was presented to Wind Tunnel and Model Testing Panel of Advisory Group for Aeronautical Research and Development, Brussels, Belgium, August 27-31, 1956). August 1956. 16p. diagrs. (NACA TN 3859)

Comparisons of some wind-tunnel- and flight-measured values of stability and control characteristics have been made for three swept-wing airplanes to show the agreement in trends and values of the data. In general, agreement of the data was good; however, where differences in the data were shown, generally they could be attributed either to specific geometric discrepancies between model and airplane or to model test techniques. Some suggestions are included for improving correlation of wind-tunnel and flight data and for analysis of the wind-tunnel data.

BRITISH REPORTS

Aeronautical Research Council (Gt. Brit.)
EXPERIMENTS WITH SLOTTED AND PERFORATED WALLS IN A TWO-DIMENSIONAL HIGH-SPEED TUNNEL. D. W. Holder, R. J. North, and A. Chinneck. 1956. 59p. diagrs., photos., tabs. (ARC R & M 2955. Supersedes ARC 14,411, TP 352, FM 1631)

Preliminary tests were made with a 7-1/2 inch by 3 inch two-dimensional induced-flow tunnel fitted with slotted or with perforated walls, and with a closed tunnel and an open jet of the same size. The experiments include observations of the pressures in the empty tunnel, and of the pressure distribution and flow pattern round a 2-inch chord airfoil at angles of attack of 0° and 2°. The reliability of the measurements on the airfoil at high subsonic speeds is estimated by comparison with measurements in the 20- by 8-inch tunnel on an airfoil of the same section and chord.

A METHOD FOR CALCULATING THE PRESSURE DISTRIBUTION OVER JET-FLAPPED WINGS. D. Kuchemann. May 1956. 38p. diagrs. (RAE Aero 2573)

The incompressible flow past an airfoil with a thin jet emerging from its lower surface somewhere near the trailing edge is considered. Based on the work of Gates, Maskell, and Spence, a simple method is described for calculating the pressure distribution over wings of nonzero thickness. The effects of finite aspect ratio and of camber are included and the method can be used for design purposes. The possible effects of sweep are briefly discussed. It is pointed out that a saddleback chordwise loading is typical for airfoils with jets and that this is the basic reason for most of the aerodynamic advantages of the jet-flap system.

Royal Aircraft Establishment (Gt. Brit.)
THE LIFT ON A THIN AEROFOIL WITH A BLOWN FLAP. D. A. Spence. May 1956. 17p. diagrs. (RAE Tech. Note Aero 2450)

The method which was previously developed for calculating the lift on a thin jet-flapped airfoil is applied to the case of airfoils with blown flaps. The classical results for attached flow on flapped airfoils without supercirculation are also obtained as a special case. Results show that the effectiveness of the jet flap scheme might be greatly increased by blowing over flaps of the order of 20 or 30 percent of the chord, rather than over the very small shrouds which have hitherto been proposed.

A THEORY OF SLENDER DELTA WINGS WITH LEADING EDGE SEPARATION. K. W. Mangler and J. H. B. Smith. April 1956. 21p. diagrs. (RAE Tech. Note Aero 2442)

Flow past a slender delta wing with a highly swept, sharp leading edge, at incidence, usually separates along the edge and a vortex sheet is formed, extending from the wing. This rolls up to form a region of flow with high vorticity, called the "core", joined to the leading edge by a vortex sheet. A potential theory for this type of flow is developed based on the assumptions of slender wing theory and of a conical

velocity field. The three-dimensional problem reduces to a two-dimensional one. The shape of the entire vortex sheet and its strength are determined by the two conditions that the flow must be parallel to the vortex sheet and the pressure continuous across it. The shape and strength of the "core" are found and a graphical method for finding the remainder of the solution is outlined. Some features of the three-dimensional and the corresponding two-dimensional flow pattern are discussed with the aid of diagrams.

Royal Aircraft Establishment (Gt. Brit.)
A PRELIMINARY SURVEY OF SOME EXPERIMENTAL RESULTS OF THE WAVE DRAG OF WINGS AT ZERO LIFT. R. A. Bishop. April 1956. 10p. diagrs., tab. (RAE Tech. Note Aero 2445)

In association with the present work on the theoretical wave drag of wings at zero lift, an examination of experimental data is in progress and a preliminary survey is given here. It appears that because of the existence of interference effects between wings and the bodies on which they are mounted, there is a shortage of experimental results from which the drag of isolated wings can be deduced, but a selection of some results which do seem reliable is made. In one instance a comparison with theoretical estimates is made.

REDUCTION OF THE EFFECT OF VIBRATIONS IN OPTICAL INVESTIGATIONS: THE BERKSHIRE COPSE LABORATORY AND 210 INCH f/15 COLLIMATOR. J. M. Naish. March 1956. 22p. diagrs., photos. (RAE Tech. Note Ph. 496)

A description is given of the monolithic design and kinematic mounting of a 210-inch collimator. Details are given of precautions taken to insure thermal stability for the collimator and for the associated-optical bench which is carried on the same foundation unit. Photoelectric probe measurements are reported which show the equipment to be suitable for determining the response function of a long-focus camera lens, the angular stability being of the order of 0.1 second of arc.

N-44950*

Royal Aircraft Establishment (Gt. Brit.)
THE SIMULATION OF MECHANICAL THRESHOLD. M. Squires. March 1956. 33p. diagrs. (RAE Tech. Note GW 403)

Three electronic analogs for the threshold behavior found in some mechanisms are described. This behavior is characterized in general by (a) a failure to develop relative motion between rubbing surfaces unless the applied tangential force (or the applied torque in the case of bearings in rotating machinery) exceeds some critical value; (b) the common occurrence of a region of bistable operation, due to reduction in the coefficient of friction with relative velocity; and (c) a range of velocities which cannot be stably maintained.

N-44951*

Royal Aircraft Establishment (Gt. Brit.)
THE EFFECT OF WING TORSION ON AILERON-TAB FLUTTER. H. Hall. April 1956. 31p. diagrs., tab. (RAE Structures 203)

Results are presented for a series of calculations on an idealized system having degrees of freedom in wing pitch, rotation of the control surface and rotation of the tab; the pitching degree of freedom is spring restrained and is intended to represent wing torsion. The tab is restrained as a trim tab or pure aerodynamic servo tab, but the results are expected to apply qualitatively to a spring tab. A comparison is made to results by Wittmeyer and Wittmeyer and Templeton where the main surface mode considered was one of vertical translation to represent wing bending. From this previous work criteria were suggested for the prevention of this type of flutter, and in an analogous manner criteria are now proposed for prevention of wing torsion-aileron-tab flutter.

SOME TESTS OF INJECTORS FOR ROCKET MOTORS USING LIQUID OXYGEN. J. Humphries and W. H. J. Riedel. February 1956. 25p. diagrs., photos., tabs. (RAE Tech. Note RPD 140)

This note describes some early work during 1950-51 to compare the behavior of three types of injector tested with liquid oxygen as oxidant and 75 percent ethyl alcohol/water and kerosene as fuels. The three injectors were of the V2, peripheral slit, and non-impinging shower or multihole types. With the alcohol fuel, the specific thrusts recorded represented approximately 70 percent, 75 percent, and 90 percent of theoretical respectively. Besides giving a high performance, the multihole injector offered the advantage of stable running with propellant injection pressures as low as 12 lb/sq inch. Only a few tests were carried out with kerosene as fuel, before the work was terminated.

TECHNIQUES FOR TESTING MODELS OF VTOL AND STOL AIRPLANES. John P. Campbell. (Presented to Wind Tunnel and Model Testing Panel of the Advisory Group for Aeronautical Research and Development, Brussels, Belgium, August 27-31, 1956). 34p. diagrs., photos.

The purpose of this paper is to describe briefly some of the techniques that have been used by the NACA during the last seven years in conducting research on VTOL and STOL airplanes. These testing techniques may be divided into two general classes: first, conventional wind-tunnel force testing techniques; and, second, the free-flying model techniques including the control-line technique. This paper is primarily concerned with the free-flying model technique; however, a brief description of some of the force-testing techniques is presented.

CURRENT NACA RESEARCH REPORTS

NACA Rept. 1251

STRESS ANALYSIS OF CIRCULAR SEMIMONOCOQUE CYLINDERS WITH CUTOUTS. Harvey G. McComb, Jr. 1955. ii, 55p. diagrs., tabs. (NACA Rept. 1251. Supersedes TN 3199; TN 3200; TN 3460)

A method is presented for analyzing the stresses about cutouts in circular semimonocoque cylinders with flexible rings. The method involves the use of so-called perturbation stress distributions which are superposed on the stress distribution that would exist in the structure with no cutout in such a way as to give the effects of a cutout. The method can be used for any loading case for which the structure without the cutout can be analyzed and is sufficiently versatile to account for stringer and shear reinforcement about the cutout.

NACA Rept. 1256

AXIALLY SYMMETRIC SHAPES WITH MINIMUM WAVE DRAG. Max. A. Heaslet and Franklyn B. Fuller. 1956. ii, 16p. diagrs. (NACA Rept. 1256. Supersedes TN 3389)

Optimum bodies consisting of a basic cylinder with added peripheral volume are derived and presented in terms of the effective radius-length ratio. Variation of this parameter from 0 to ∞ encompasses the spectrum of results from slender to two-dimensional. A reciprocal theorem leads to simple interpretation of variational problems.

NACA Rept. 1258

A WIND-TUNNEL TEST TECHNIQUE FOR MEASURING THE DYNAMIC ROTARY STABILITY DERIVATIVES AT SUBSONIC AND SUPERSONIC SPEEDS. Benjamin H. Beam. 1956. ii, 14p. diagrs., photos. (NACA Rept. 1258. Supersedes TN 3347)

An experimental technique for measuring dynamic stability derivatives of a model airplane in a wind tunnel is described. A single-degree-of-freedom, feedback-controlled, forced-oscillation system was used to measure the stability derivatives which are important in estimating the lateral and longitudinal oscillatory motions of a rigid airplane. Some representative experimental data are included.

NACA Rept. 1260

STUDIES OF THE SPEED STABILITY OF A TANDEM HELICOPTER IN FORWARD FLIGHT. Robert J. Tapscott and Kenneth B. Amer. 1956. ii, 12p. diagrs., photos., tab. (NACA Rept. 1260. Supersedes RM L53F15a)

Analytical and experimental studies and corresponding pilots' opinions of the speed stability of a tandem helicopter are presented and means for improving the speed stability are discussed. An analytical expression is derived for use in predicting changes in speed stability of a tandem helicopter brought about by changes in the rotor geometry. Constants for use with the analytical expression are presented in chart form.

NACA Rept. 1261

THE NEAR NOISE FIELD OF STATIC JETS AND SOME MODEL STUDIES OF DEVICES FOR NOISE REDUCTION. Leslie W. Lassiter and Harvey H. Hubbard. 1956. i, 12p. diagrs., photos. (NACA Rept. 1261. Supersedes TN 3187)

Experimental studies of the pressure fluctuations near jets were made during unchoked operation of both a full-scale turbojet engine and a 1-inch-diameter high-temperature model jet and during choked operation of model jets of 0.275-inch to 2.00-inch diameter with unheated air. Frequency spectra and spatial distributions of pressure magnitude are given for the full-scale configuration and model data are used to illustrate probable trends at different operating conditions for the unchoked jets. Model tests for choked operation indicate the presence of a discrete-frequency component, and shadowgraph records illustrate that an unusual type of flow formation is associated with this condition. The frequency of this component is shown to be somewhat related to the shock-separation distances and to nozzle diameter. Laboratory methods of reducing the magnitude of pressure fluctuations from choked and unchoked jets are discussed and sample illustrations are given.

MEASUREMENTS OF BOUNDARY-LAYER TRANSITION AT LOW SPEED ON TWO BODIES OF REVOLUTION IN A LOW-TURBULENCE WIND TUNNEL. Frederick W. Boltz, George C. Kenyon, and Clyde Q. Allen. September 1956. 14p. diagrs., photos., tabs. (NACA RM A56G17)

An investigation of the location of transition from laminar to turbulent flow in the boundary layer on two bodies of revolution of fineness ratios 7.5 and 9.0 has been made in the Ames 12-foot pressure wind tunnel. Transition measurements were obtained by the use of microphones installed within the bodies. Also presented are the pressure distributions for both bodies of revolution.

NACA TM 1383

FINITE SPAN WINGS IN COMPRESSIBLE FLOW. E. A. Krasilshchikova. September 1956. 130p. diagrs. (NACA TM 1383. From: Scientific Records of the Moscow State University, v.154, Mechanics no.4, 1951, with appendix condensed from a document "Modern Problems of Mechanics," Govt. Pub. House of Tech. Theor. Literature, (Moscow, Leningrad) 1952.)

Equations are developed using the source distribution method for the velocity potential function and pressure on thin wings in steady and unsteady motion. Closed form solutions are given for harmonically oscillating wings of general plan form including the effect of the wing wake. Some useful examples are presented in an appendix for arrow, semielliptical, and hexagonal plan form wings. The paper is essentially a summary of previous work by the author.

NACA TN 3680

INTERACTION OF GRIDS WITH TRAVELING SHOCK WAVES. Darshan Singh Dosanjh, Johns Hopkins University. September 1956. 80p. diagrs., photos. (NACA TN 3680)

Grids were mounted in the path of traveling shock waves in a shock tube. The incident shock wave after its collision with the grid split into transmitted and reflected waves. The emergence, growth, and speeds of these shock fronts were recorded with shadowgraphic and hot-wire techniques. The oscillograms of the hot-wire response of various transient flow regions are examined and some preliminary conclusions regarding the state of the flow downstream of the grid are reached.

NACA TN 3744

SUPERSONIC FLOW PAST NONLIFTING BUMPED AND INDENTED BODIES OF REVOLUTION. F. Edward McLean and Conrad Rennemann, Jr. September 1956. 39p. diagrs. (NACA TN 3744)

Linear-theory values of the supersonic pressure field and wave drag of nonlifting bumped and indented bodies of revolution are presented and compared with the corresponding properties of a smooth body. The comparisons indicate that relatively small surface irregularities cause large pressure disturbances and changes in wave drag. The interference drag produced by bumps and indentations is discussed and a correction for the curvature of the characteristics is applied.

NACA TN 3746

INITIAL RESULTS OF A FLIGHT INVESTIGATION OF THE WING AND TAIL LOADS ON AN AIRPLANE EQUIPPED WITH A VANE-CONTROLLED GUST-ALLEVIATION SYSTEM. T. V. Cooney and Russell L. Schott. September 1956. 31p. diagrs., photos. (NACA TN 3746)

Results are given of an analysis of wing and horizontal-tail spar strains measured on a twin-engine light transport airplane which was modified for the installation of a control system to alleviate airplane motions in turbulent air and thus improve passenger comfort. From a sample of the measurements obtained in flight through clear-air turbulence, normal acceleration at the airplane center of gravity was reduced 43 percent, wing main-spar bending strains were reduced, and wing-spar shear strains were increased. Horizontal-tail shear and bending strains were increased. Measurements of aerodynamic loads obtained in a pull-up with the gust-alleviation system in operation are also presented.

NACA TN 3755

SOME OBSERVATIONS ON THE RELATIONSHIP BETWEEN FATIGUE AND INTERNAL FRICTION. S. R. Valluri, California Institute of Technology. September 1956. 42p. diagrs., photos., tabs. (NACA TN 3755)

Results are presented of an investigation made to determine the internal friction and fatigue strength of commercially pure 1100 aluminum under repeated stressing in torsion at various temperatures and stress levels in an effort to find if there exists any correlation between internal friction and fatigue characteristics.

NACA TN 3761

TURBULENT SHEAR SPECTRA AND LOCAL ISOTROPY IN THE LOW-SPEED BOUNDARY LAYER. Virgil A. Sandborn and Willis H. Braun. September 1956. 34p. diagrs. (NACA TN 3761)

From measurements of turbulent shear spectra together with previously reported longitudinal turbulent energy spectra, the concept of local isotropy in a low-speed boundary layer was examined. Results of these measurements and measurements of the time derivatives of turbulent velocities in the x- and y-directions for various frequency bands showed no evidence of local isotropy in the boundary layer. Several methods (based on isotropy) of evaluating the turbulent dissipation term failed to give consistent answers, further emphasizing a lack of local isotropy.

NACA TN 3762

DRAG COEFFICIENTS FOR DROPLETS AND SOLID SPHERES IN CLOUDS ACCELERATING IN AIR-STREAMS. Robert D. Ingebo. September 1956. 31p. diagrs., photos., tab. (NACA TN 3762)

Linear accelerations for droplets and solid spheres (in clouds) in airstreams were determined from sphere diameter and velocity data obtained with a high-speed camera developed at the NACA Lewis laboratory. An empirical expression $C_D = 27/Re^{0.84}$ correlated drag coefficient C_D with Reynolds number Re for the case of accelerating droplets (iso-octane, water, and trichloroethylene) and solid spheres (magnesium and calcium silicide). This expression was derived for a Reynolds number range of 6 to 400, which included a range of airstream pressure, temperature, and velocity conditions. Trajectory equations for spheres were also derived.

NACA TN 3764

NEAR NOISE FIELD OF A JET-ENGINE EXHAUST. II - CROSS CORRELATION OF SOUND PRESSURES. Edmund E. Callaghan, Walton L. Howes, and Willard D. Coles. Appendix: CORRELATION COMPUTER. Channing C. Conger and Donald F. Berg. September 1956. 53p. diagrs., photos., tab. (NACA TN 3764)

Pressure cross correlations were obtained over a range of jet velocities both longitudinally and laterally for the overall sound pressure and for several frequency bands. The region of positive correlation was found to increase with distance downstream of the nozzle exit and was greater for lateral than for longitudinal correlations. In general, little change in the correlation curves was found as a function of jet velocity or frequency band width. Measurements made with a fixed and a movable microphone in a plate showed correlations similar to the free-field results. The results are interpreted in terms of pressure loads on surfaces.

NACA TN 3765

SOME EFFECTS OF SMALL-SCALE FLOW DISTURBANCE ON NOZZLE-BURNER FLAMES. Edgar L. Wong. September 1956. 19p. diagrs., photos., tabs. (NACA TN 3765)

Laminar-like and brush-like propane-air flames were obtained when wire grids were used as turbulence generators in a 1/2-inch nozzle burner. The laminar-like flames for grid-disturbed flow had a slightly higher burning velocity than "true" laminar flames (no grid used). The brush-like flames were similar to those obtained with pipe turbulent flow. Their burning-velocity dependence on a "flow disturbance" Reynolds number compared favorably with that obtained for pipe turbulent flames. Hot-wire-anemometer equipment was used to measure the flow disturbance intensity in the cold flow with and without the grids in place.

NACA TN 3767

THE USE OF PERFORATED INLETS FOR EFFICIENT SUPERSONIC DIFFUSION. John C. Evvard and John W. Blakey. September 1956. 35p. diagrs., photo. (NACA TN 3767. Supersedes RM E51B10)

The use of wall perforations on supersonic diffusers to avoid the internal contraction-ratio limitation is described. Experimental results at a Mach number of 1.85 on a preliminary model of a perforated diffuser having a geometric internal contraction ratio of 1.49 (the isentropic value) are presented. A theoretical discussion of the flow coefficients as well as the size and the spacing of the perforations is also included. At angles of attack of 0°, 3°, and 5°, total-pressure recoveries of 0.931, 0.920, and 0.906, respectively, were obtained.

NACA TN 3769

FURTHER INVESTIGATION OF THE FEASIBILITY OF THE FREEZE-CASTING METHOD FOR FORMING FULL-SIZE INFILTRATED TITANIUM CARBIDE TURBINE BLADES. E. M. Grala. October 1956. 19p. diagr., photos., tabs. (NACA TN 3769)

A method of casting a full-size cermet turbine blade from titanium carbide was investigated. An extremely thick slip of titanium carbide was prepared with a small amount of binder, cast into a mold by vibration, centrifuged, and frozen to retain the shape of the mold. The casting was then dried in an absorbent sand and sintered by conventional means. The porous casting could then be infiltrated with a nickel- or cobalt-base alloy.

NACA TN 3772

EFFECT OF THREE DESIGN PARAMETERS ON THE OPERATING CHARACTERISTICS OF 75-MILLIMETER-BORE CYLINDRICAL ROLLER BEARINGS AT HIGH SPEEDS. William J. Anderson. October 1956. 37p. diagrs., photo., tabs. (NACA TN 3772)

A total of 30 bearings were run at loads to 368 pounds and DN values to 2.1×10^6. Roller axial clearance ratio had no significant effect on bearing temperature, cage slip, wear, or high-speed operating characteristics except at the lowest clearance ratio (0.0005) where failures occurred. Bearing temperatures were minimum at a cage diametral clearance ratio of about 0.004. Cage land width-diameter ratio had little effect on bearing temperature. At a 368-pound load, cage wear increased with increasing cage land width-diameter ratio.

NACA TN 3773

THE DESIGN OF BRITTLE-MATERIAL BLADE ROOTS BASED ON THEORY AND RUPTURE TESTS OF PLASTIC MODELS. André J. Meyer, Jr., Albert Kaufman, and William C. Caywood. September 1956. 46p. diagrs., photos., tab. (NACA TN 3773. Supersedes RM E53C12)

Theoretical design charts based on Neuber's equations for symmetrically located notches are presented for estimating the approximate rupture strengths of blade roots made from brittle materials. The limit of applicability of the theoretical charts is shown as determined by rupture tests of plastic models. The optimum proportions among overall root width, neck width, notch radius, and notch depth are determined from the design charts. Eighteen different root designs were investigated, their relative strengths were evaluated analytically and experimentally, and the results were compared. A dovetail root having the optimum proportions as established by this investigation was the strongest root evaluated.

NACA TN 3779

TENTATIVE METHOD FOR CALCULATION OF THE SOUND FIELD ABOUT A SOURCE OVER GROUND CONSIDERING DIFFRACTION AND SCATTERING INTO SHADOW ZONES. David C. Pridmore-Brown and Uno Ingard, Massachusetts Institute of Technology. September 1956. 33p. diagrs. (NACA TN 3779)

A semiempirical method is given for the calculation of the sound field about a source over ground considering the effects of vertical temperature and wind gradients as well as scattering of sound by turbulence into shadow zones. The diffracted field in a wind-created shadow zone is analyzed theoretically in the two-dimensional case and is shown to be similar to the results obtained for a temperature-created shadow field as given in NACA TN 3494.

NACA TN 3788

STABILITY DERIVATIVES OF CONES AT SUPERSONIC SPEEDS. Murray Tobak and William R. Wehrend. September 1956. 43p. diagrs. (NACA TN 3788)

The aerodynamic stability derivatives due to pitching velocity and vertical acceleration are derived for circular cones traveling at supersonic speeds. Both first-order and a combination of first- and second-order potential solutions are obtained, and, in calculations for the forces, no approximations are made to the tangency condition or the isentropic pressure relation. In addition, expressions for the forces, moments, and stability derivatives of arbitrary bodies of revolution are derived from Newtonian impact theory.

NACA TN 3789

THE RESULTS OF WIND-TUNNEL TESTS TO A MACH NUMBER OF 0.90 OF A FOUR-ENGINE PROPELLER-DRIVEN AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. George G. Edwards, Jerald K. Dickson, Fred B. Sutton, and Fred A. Demele. September 1956. 171p. diagrs., photo., tabs. (NACA TN 3789. Supersedes RM A53I28)

The effects of operating propellers on the longitudinal characteristics of the model have been investigated at thrust coefficients up to 0.9 per propeller at Mach numbers from 0.082 to 0.90 and at Reynolds numbers from 1,000,000 to 8,000,000. Variations in the model included different heights and incidences of the horizontal tail, split flaps, several propeller-blade angles, and independent as well as simultaneous operation of the inboard and outboard propellers. Coefficients of lift, longitudinal force, pitching moment, propeller thrust, and propeller power are presented.

NACA TN 3790

ANALYSIS OF WIND-TUNNEL TESTS TO A MACH NUMBER OF 0.90 OF A FOUR-ENGINE PROPELLER-DRIVEN AIRPLANE CONFIGURATION HAVING A WING WITH 40° OF SWEEPBACK AND AN ASPECT RATIO OF 10. George G. Edwards, Donald A. Buell, Fred A. Demele, and Fred B. Sutton. September 1956. 170p. diagrs., photos., tabs. (NACA TN 3790. Supersedes RM A54F14)

Experimental data published in NACA TN 3789 are analyzed. The effects of operating propellers on the longitudinal characteristics of the model are separated into various components to illustrate the origin, nature, and intensity of each. The analysis indicates certain configuration changes which would reduce the adverse effects of propellers on the longitudinal stability.

NACA TN 3791

ON A METHOD FOR OPTIMIZATION OF TIME-VARYING LINEAR SYSTEMS WITH NONSTATIONARY INPUTS. Marvin Shinbrot. September 1956. 39p. (NACA TN 3791)

By means of examples, a new method is illustrated for optimizing, over a finite interval of time, time-varying systems with stationary or nonstationary statistical inputs. The method depends on the correlation functions being of a certain type, which, fortunately, is the type found in a large number of practical problems of importance.

NACA TN 3798

A THEORETICAL ESTIMATE OF THE EFFECTS OF COMPRESSIBILITY ON THE PERFORMANCE OF A HELICOPTER ROTOR IN VARIOUS FLIGHT CONDITIONS. Alfred Gessow and Almer D. Crim. October 1956. 33p. diagrs. (NACA TN 3798)

The effects of compressibility arising from high-tip-speed operation on the flapping, thrust, and power of a helicopter rotor in forward speed are investigated for a particular set of airfoil characteristics. Tip-speed ratios ranging from 0.2 to 0.5 were covered at several tip-speed values.

NACA TN 3800

EXPLORATORY INVESTIGATION OF THE EFFECTIVENESS OF BIPLANE WINGS WITH LARGE-CHORD DOUBLE SLOTTED FLAPS IN REDIRECTING A PROPELLER SLIPSTREAM DOWNWARD FOR VERTICAL TAKE-OFF. Robert H. Kirby. October 1956. 22p. diagrs., tab. (NACA TN 3800)

Results are presented from static-force tests on biplane wings with large-chord double slotted flaps which turn the slipstream of a single counterrotating propeller downward for vertical take-off. The investigation provided information on the effect of chord length, flap deflection, propeller position, end plates, fuselage, and ground proximity on the efficiency of the wing system in turning the propeller slipstream.

NACA TN 3801

EXPERIMENTAL INVESTIGATION OF THE STRENGTH OF MULTIWEB BEAMS WITH CORRUGATED WEBS. Allister F. Fraser. October 1956. 17p. diagrs., photos., tabs. (NACA TN 3801)

The results of an experimental investigation of the strength of multiweb beams with corrugated webs are reported. Included in the investigation were two types of connection between the web and the skin. A comparison between the structural efficiency of corrugated-web and channel-web multiweb beams is presented, and it is shown that, for a considerable range of the structural index, corrugated-web beams can be built which are structurally more efficient than channel-web beams.

NACA TN 3803

BAND-PASS SHOCK AND VIBRATION ABSORBERS FOR APPLICATION TO AIRCRAFT LANDING GEAR. Emanuel Schnitzer. October 1956. 27p. diagrs. (NACA TN 3803)

In order to overcome rigidity limitations of conventional shock absorbers over certain frequency ranges or rates of load application, frequency-discriminating band-pass shock absorbers are introduced and the principles of operation are explained. The application of a low-pass shock strut to high-speed aircraft for which conventional oleo struts become rigid links when loads are rapidly applied during landing or taxiing over steep bumps is discussed. Theoretical solutions indicate marked load reductions for the low-pass shock absorbers for steep bumps or water waves and equal actions of both struts for long hills or swells. Possible extension of the principles to double-action band-pass vibration absorbers is discussed.

NACA TN 3805

CALCULATION OF THE FORCES AND MOMENTS ON A SLENDER FUSELAGE AND VERTICAL FIN PENETRATING LATERAL GUSTS. John M. Eggleston. October 1956. 20p. diagrs., tab. (NACA TN 3805)

A theory is presented for calculating the variation with frequency of the lateral-force and yawing-moment coefficients due to sinusoidal side gusts passing over the profile of a simple fuselage—vertical-fin combination. The analysis is based on slender-body theory. The method considers the penetration effect of both fuselage and vertical tail in calculating side force and yawing moment due to side gusts, as opposed to a simple lag concept which considers the flow angle to be uniform over the configuration.

NACA TN 3808

WIND-TUNNEL CALIBRATION OF A COMBINED PITOT-STATIC TUBE AND VANE-TYPE FLOW-ANGULARITY INDICATOR AT MACH NUMBERS OF 1.61 AND 2.01. Archibald R. Sinclair and William D. Mace. October 1956. 11p. diagrs., photo. (NACA TN 3808)

A limited calibration of a combined pitot-static tube and vane-type flow-angularity indicator has been made in the Langley 4- by 4-foot supersonic pressure tunnel at Mach numbers of 1.61 and 2.01. The results indicated that the angle-of-attack indications were affected by upwash about the probe tube and that the angle-of-yaw indications were affected by unsymmetric shock effects at low angles of attack.

NACA TN 3827

EXPERIMENTAL INVESTIGATION OF A LIGHTWEIGHT ROCKET CHAMBER. John E. Dalgleish and Adelbert O. Tischler. October 1956. 11p. photos. (NACA TN 3827. Supersedes RM E52L19a)

Experiments have been conducted with a jacketed rocket combustion chamber that was fabricated by hydraulic forming from sheet metal. Rocket combustion chambers made by this method have been used successfully. Runs with these combustion chambers have been made at overall heat-transfer rates of 2.5 Btu per square inch per second with water cooling and also with ammonia as a regenerative coolant.

Royal Aircraft Establishment (Gt. Brit.)
PRECISION PLANNING TECHNIQUES AS APPLIED TO THE MANUFACTURE OF SUPERSONIC WIND TUNNEL MODELS. G. W. Rawlings. (For presentation at the 8th Meeting of the Advisory Group for Aeronautical Research and Development Wind Tunnel Panel, Rome). February 1956. 20p. diagrs., photos. (RAE Tech. Note ADW 2)

The considerable development in recent years in the use of supersonic and transonic wind tunnels has created an increasing demand for scale prototypes or

models and this in turn has given rise to quite a variety of production problems. It is proposed in this paper to discuss these problems and to outline the methods by which, in some measure, they have been met. Since the accuracy or validity of any conclusions reached from wind tunnel testing is so closely related to the accuracy or quality of the models used in the tests, it is essential that the standard of precision of the models shall at least correspond to the standard of precision of the wind tunnels in which they are used and it is from this necessity that the production problems arise. The model types to be discussed fall broadly into three classes, namely, airfoil research models, complete aircraft models, and guided missile models. In the airfoil research class, the models may be either in the form of a single wing arranged for side or base mounting, or in the form of a complete aircraft mounted upon a mandrel adapter or sting.

Royal Aircraft Establishment (Gt. Brit.)
AN INVESTIGATION INTO THE SUITABILITY OF SHOCK TESTING AS A MEANS OF THERMIONIC VALVE SELECTION FOR MISSILE CONTROL SYSTEMS. L. A. J. Lawrence and C. A. Mountford. April 1956. 41p. diagrs., photos., tabs. (RAE Tech. Note GW 411)

A method is described by which VX8122 subminiature valves (vacuum tubes) were initially subjected to controlled shock tests and to controlled vibration tests. The quantities measured were zero drift and microphony. The results are tabulated and an analysis is made to correlate the data from the tests. A description is given of the equipment used for generation and control of both shock and vibration; details of the equipment for measurement and recording are also given.

BRIEF DESCRIPTION OF THE R. A. E. INTERMITTENT SUPERSONIC WIND TUNNEL PLANT. K. G. Winter. June 1956. 15p. diagrs., photos. (RAE Tech.Note Aero 2459)

The plant is vacuum-operated on a closed circuit with storage of the air in a flexible container. The useful Mach number range is up to about 4.5. For the largest of the tunnels (15 in. x 16 in.) the maximum running time is of the order of 20 seconds over the whole Mach number range. Runs of 10 to 15 seconds duration can be made every 5 minutes.

N-46128*

Royal Aircraft Establishment (Gt. Brit.)
NOTE ON STRAIN GAUGE RECORDING EQUIPMENT FOR THE R. A. E. INTERMITTENT SUPERSONIC WIND TUNNELS. K. G. Winter and E. J. Petherick. June 1956. 12p. diagrs., photos. (RAE Tech. Note Aero 2461)

A description is given of a simple system for photographing, up to six times per second, revolution counters driven from strain gage balance indicators. A further proposed system using punched cards is also described. Results show that, even with comparatively slow strain gage balance indicators, satisfactory recording of the loads on a model over a wide incidence range can be obtained in a run of 20 seconds duration.

Royal Aircraft Establishment (Gt. Brit.)
THE FATIGUE STRENGTH OF ALUMINIUM ALLOY SHEET TO SPECIFICATION D. T. D.546 USING SPECIMENS OF TWO DIFFERENT SIZES. N. J. Wadsworth. April 1956. 12p. diagrs. (RAE Tech. Note Met. 237)

The effect of specimen size on the fatigue strength of specimens cut from 16 gage Alclad D. T. D. 546 sheet was investigated at an endurance of 10^5 cycles. Specimens 1 inch and 0.3 inch wide with and without a central hole (giving an elastic stress concentration factor of 2.44) were tested in a Haigh machine. The strength reduction factor due to the hole was 1.8 in the large specimens and 1.48 on the small. There was little or no difference in the strength of the plain specimens.

LOADS ON A MODEL DURING STARTING AND STOPPING OF AN INTERMITTENT SUPERSONIC WIND TUNNEL. K. G. Winter and C. S. Brown. May 1956. 17p. diagrs., photos. (RAE Tech. Note Aero 2453)

Measurements are given of the loads on a model during starting and stopping of an intermittent supersonic wind tunnel at Mach numbers of 2.00 and 2.48. Qualitative agreement is obtained with a simple theory but a need is evident for further measurements at higher Mach numbers. The use of a model loading coefficient in terms of tunnel stagnation pressure is proposed.

THE FOULING OF TURBINE BLADES BY FUEL ASH. PART V. CORROSION TESTS WITH VARIOUS HEAT RESISTING MATERIALS. F. S. E. Whitcher. June 1956. 36p. diagrs., tabs. (NGTE R. 192)

The resistance of selected materials to accelerated oxidation by vanadium bearing fuel oil ash has been assessed by means of a series of rig tests. It is shown that alloys based on nickel or cobalt are more resistant to this type of corrosion than those based on iron. It is also shown that a considerable reduction in corrosion is achieved by the addition of magnesium to the fuel. For iron base alloys at temperatures up to 700° C, and for nickel and cobalt base alloys up to 800° C the oxidation is in many cases reduced to below that found under "ash free" conditions.

National Gas Turbine Establishment (Gt. Brit.)
A METHOD OF CORRECTION OF COMPRESSOR CHARACTERISTICS FOR CHANGE OF WORKING FLUID SPECIFIC HEAT. S. J. Moyes. July 1956. 13p. diagr. (NGTE Memo. M. 276)

In some applications, the specific heat of the working fluid in the compressor of a gas turbine engine differs considerably from that obtaining in rig tests, due to a difference in temperature levels. It thus becomes necessary to ascertain the effect of changes of specific heat on compressor characteristics. This may be done using stage-by-stage analysis and synthesis, but a more direct and less laborious method is obviously desirable. This memorandum presents such a method for an axial flow compressor, based on aerodynamic relationships, the application of the method being illustrated by an example. The method is limited to cases where Mach number effects in the compressor are not present or are small. It is thought, however, that the method has a useful range of application and also is capable of being extended to deal with changes in working fluid properties other than specific heat.

APPLICATION OF SEQUENCE TRANSFORM ANALYSIS TO THE DESIGN OF SAMPLING CONTROL SYSTEMS. A. R. Boothroyd and J. H. Westcott. March 1956. 53p. diagrs. (RAE Tech. Note GW 405)

Analytical methods are described appropriate to linear control systems in which the input is in the form of discrete samples, rather than continuous. The techniques described are applicable to guided weapon systems in which the guidance information is obtained intermittently. The analysis of sampling systems by the sequence transform method is presented, particular reference being made to the important contributions of R. H. Barker in this field. Control systems involving basically the double integrations of a clamped error signal are considered and Barker's method of stabilizing the system in regard to its response sequence at the sampling times is applied.

Forest Products Research Lab., Dept. of Scientific and Industrial Research (Gt. Brit.) COMPOSITE WOOD SECTION. TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. YELLOW SERAYA - SHOREA (RICHETIA) SP. - NORTH BORNEO. CONSIGNMENT NO. 861 - GIVING TWO BILLETS FROM TWO TREES; WEIGHT - VARIABLE, RANGES FROM 32 TO 55 LB. PER CU. FT. AT 15 PER CENT MOISTURE CONTENT. TIMBER PROVISIONALLY CLASSIFIED AS GROUP I. (PROGRESS REPORT THIRTY-FIVE). April 1956. 8p. tabs. (Forest Products Research Lab., DSIR)

N-46288*

Forest Products Research Lab., Dept. of Scientific and Industrial Research (Gt. Brit.) COMPOSITE WOOD SECTION. TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. KAPUR - DRYOBALANOPS LANCEOLATA - NORTH BORNEO. CONSIGNMENT NO. 842 GIVING TWO BILLETS FROM TWO TREES; WEIGHT - 46 LB./CUBIC FEET AT 15 PER CENT MOISTURE CONTENT. TIMBER PROVISIONALLY CLASSIFIED AS GROUP III. (PROGRESS REPORT THIRTY-SIX). April 1956. 7p. tabs. (Forest Products Research Lab., DSIR)

N-46289*

Forest Products Research Lab., Dept. of Scientific and Industrial Research (Gt. Brit.) COMPOSITE WOOD SECTION. TRIALS OF TIMBERS FOR PLYWOOD MANUFACTURE. KERUING - DIPTEROCARPUS TAWENSIS - NORTH BORNEO. CONSIGNMENT NO. 860 GIVING TWO BILLETS FROM TWO TREES; WEIGHT - VARIABLE, INDIVIDUAL SPECIES VARY BETWEEN 39 AND 59 LB/CU. FT. AT 15 PER CENT MOISTURE CONTENT. TIMBER PROVISIONALLY CLASSIFIED AS GROUP III. (PROGRESS REPORT THIRTY-SEVEN). April 1956. 8p. tabs. (Forest Products Research Lab., DSIR)

Advisory Group for Aeronautical Research and Development. COMPRESSORS FOR HIGH-SPEED WIND TUNNELS. Andrew A. Fejer, University of Toledo and James Clark, Air Research Manufacturing Company of Phoenix. Wilbur C. Nelson, University of Michigan, Editor. January 1956. 216p. diagrs., photos. (AGARDograph 14)

This study is concerned with the compressor drive systems for high-speed wind tunnels of the continuous type. It contains information regarding the aerodynamic characteristics of wind tunnel circuits from which the compressor requirements can be established, presents a method to guide in the selection of the compressor type, and discusses compressor drives utilizing various types of prime movers. It outlines some of the aerodynamic and mechanical considerations underlying the design and operation of wind tunnel drives including a discussion of vibrational problems encountered in systems of this type.
